The phenomena exhibited between loadstones or magnets and iron have long attracted attention; and the use to which the polarity of the loadstone has been applied, namely, the directing the course of a ship through the pathless ocean, has rendered these phenomena extremely interesting. They are specified by the term magnetism. Considerable progress has been made in the arrangement and generalization of them; but we have by no means been able hitherto to bring them all under one simple fact. The attention has been too much turned to the discovery of the ultimate cause of magnetism; whereas we should have rather employed our ingenuity in discovering all the general laws, in the same manner as Kepler and Newton did with respect to the celestial phenomena, without troubling themselves with the cause of gravitation. Dr. Gilbert of Colchester was the first who considered the magnetical phenomena in the truly philosophical manner; and

PHYSICS.

his treatise *De Magnete* may be considered as the first and one of the most perfect specimens of the Baconian or inductive logic. It is indeed an excellent performance; and when we consider its date, 1580, it is a wonder. *Æpinus's Tentamen Theoriæ Magnetismi* is a most valuable work, and contains all the knowledge which we have as yet of the subject.

There is another class of mechanical phenomena which has a considerable affinity with the magnetical; we mean the phenomena called electrical. Certain bodies, when rubbed or otherwise treated, attract and repel other bodies, and occasion a great variety of sensible motions in the neighbouring bodies. Philosophers have paid much attention to these appearances of late years, and established many general laws concerning them. But we have not been more successful in bringing them all under the fact, and thus establishing a complete theory of them, than in the case of magnetism. Franklin and *Æpinus* are the authors who have been most successful in this respect. Dr. Franklin in particular has acquired great celebrity by his most sagacious comparison of the phenomena; which has enabled him to establish a few general laws, almost as precise as those of Kepler, and of equally extensive influence. His discovery too of the identity of thunder and electricity has given an importance and dignity to the whole subject.

There are many phenomena of electricity which cannot be called mechanical, and are of the most curious and interesting kind. As these have little connection with any of the other great branches of physical science, they have generally been considered in treatises of natural philosophy; and along with inquiries into the original cause of electricity in general, continue to engage much of our attention. See **ELECTRICITY** and **VOLTAISM**.

The appearances which are presented to us by our sense of seeing form another class, which have always been considered as making a branch of natural philosophy in all seminaries of learning. It does not, however, obviously appear, that they are mechanical phenomena. The intimate nature of light is still a secret. Fortunately it is not necessary to be known to give us a very perfect theory of the chief phenomena. The general laws of optics are so few, so simple, and so precise, that our theories are perhaps more perfect here than in any other branch of physics; but these theories are as yet far removed from the rank of primary facts. Many unknown events happen before the phenomenon comes under the hands of the ordinary optician, so as to become the subjects of the simple laws of reflection and refraction. It may even be doubted, and has been doubted, whether the phenomena of optics are cases of body in motion; whether all the lines which the optician draws are any thing but the directions along which certain qualities are exerted. See **OPTICS** and **VISION**.

The questions about the activity or inactivity of matter are not physical, but metaphysical. Natural philosophy, it is true, commonly takes it for granted that matter is wholly inactive; but it is not of any moment in physics whether this opinion is true or false; whether matter is acted on according to certain laws, or whether it acts of itself according to the same laws, makes no difference to the natural philosopher. It is his business to discover the laws which really obtain, and to apply these to the solution of subordinate

phenomena: but whether these laws arise from the nature of some agent external to matter, or whether matter itself is the agent, are questions which may be above his comprehension, and do not immediately concern his proper business.

We shall conclude this disquisition by remarking that there is no class of men to whom this science is of more service than to those who hold the honourable office of teachers of religion. Their knowledge in their own science, and their public utility, are prodigiously hurt by ignorance of the general frame and constitution of nature; and it is much to be lamented that this science is so generally neglected by them, or considered only as an elegant accomplishment: nay, it is too frequently shunned as a dangerous attainment, as likely to unhinge their own faith, and taint the minds of their hearers. We hope, however, that few are either so feebly rooted in the belief of the great doctrines of religion as to fear this, or of minds so base and corrupted as to adopt and inculcate a belief which they have any suspicion of being ill-founded. But many have a sort of horror at all attempts to account for the events of nature by the intervention of general causes, and think this procedure derogatory to the Divine nature, and inconsistent with the doctrine of his particular providence; believing, that "a sparrow does not fall to the ground without the knowledge of our heavenly Father." Their limited conceptions cannot perceive, that, in forming the general law, the Great Artist did at one glance see it in its remotest and most minute consequence, and adjust the vast assemblage so as completely to answer every purpose of His providence. There never was a more eager inquirer into the laws of nature, or more ardent admirer of its glorious Author, than the hon. Robert Boyle. This gentleman says, that he will always think more highly of the skill and power of that artist who should construct a machine, which, being once set a-going, would of itself continue its motion for ages, and from its inherent principles continue to answer all the purposes for which it was first contrived, than of him whose machine required the continual aid of the hand which first constructed it. It is owing to great inattention that this aversion to the operation of secondary causes has any influence on our mind. What do we mean by the introduction of secondary causes? How do we infer the agency of any cause whatever? Would we ever have supposed any cause of the operations of nature, had they gone on without any order or regularity? Or would such a chaos of events, any more than a chaos of existences, have given us any notion of a forming and directing hand? No surely. We see the hand of God in the regular and unvaried course of nature, only because it is regular and unvaried. The philosopher expresses this by saying, that the phenomena proceed by unalterable laws. Greatly mistaken, therefore, are they who think that we supersede the existence of mind and of providence when we trace things to their causes. A physical law, being an unvaried fact, is an indication, and the strongest possible indication, of an unerring mind, who is incapable of change, and must do to-day what He always did: for to change is to deviate from what is best. The operations of unerring mind will therefore be regular and invariable. Physical laws, therefore, or secondary causes, are the best proofs of unerring wisdom. Such regularity of conduct is universally considered as indications of wisdom

among men. The wise man is known by the constancy of his conduct, while no man can depend on the future conduct of a fool.

And what astonishing evidences of wisdom do we not observe in the general laws of the material world! They will ever be considered by the intelligent philosopher as the most glorious display of inconceivable wisdom, which has been able, by means so few and so simple, to produce effects which by their grandeur astonish our feeble understandings, and by their inexhaustible variety elude all possibility of enumeration.

While the teachers of religion remain ignorant of the beautiful laws of nature, the great characteristics of the wisdom and goodness of the Almighty Creator, their hearers are deprived of much sublime pleasure; God is robbed of that kind of praise which he would have received from an enlightened people; and the worship he receives, however sincere, may be tainted with mean notions of his attributes, if it be accompanied by any notions at all.

PHYSIOGNOMER. PHYSIOGNOMIST.
s. (from *physiognomy*.) One who judges of the temper or future fortune by the features of the face (*Peacham. Dryden*).

PHYSIOGNOMIC. PHYSIOGNOMONIC.
a. (*φυσιογνωμονικός*.) Drawn from the contemplation of the face; conversant in contemplation of the face.

PHYSIOGNOMY. (*physiognomia*, *φυσιογνωμία*; from *φύσις*, nature, and *γινωσκω*, to know.) "The science by which the dispositions of mankind are discoverable by the features of the body, and especially by those of the countenance." Aristotle, who first employed this term, and professedly treated of the subject it indicates, has given this definition of the study. His leading principle in treating of it was the following: a peculiar form of body is invariably accompanied by a peculiar disposition of mind: a human intellect is never found in the corporeal form of a beast; and the mind and body exercise a reciprocal affection over each other: thus in intoxication and mania, the mind exhibits the affections of the body; and in fear, in joy, &c. the body inversely displays the affections of the mind.

From such facts he argues, that when in man a particular bodily character appears, which by prior experience and observation has been found uniformly accompanied by a certain mental disposition, with which therefore it must have been necessarily connected; we are entitled in all such cases to infer the disposition from the appearance. Our observations, he conceives, may be drawn from other animals as well as from men: for, as a lion possesses one bodily form and mental character, a hare another, the corporeal characteristics of the lion, such as strong hair, deep voice, large extremities, discernible in a human creature, denote the strength and courage of that noble animal; while the slender extremities, soft down, and other features of the hare, visible in a man, betray the mental character of that pusillanimous creature.

Upon this principle Aristotle treats of the corporeal features of man; and the correspondent dispositions, so far as observed: he illus-

trates them by the analogy just mentioned, and in some instances he attempts to account for them by physiological reasoning.

At the early period in which Aristotle wrote, his theory, plausible certainly, and even probable, displays his usual penetration, and a considerable degree of knowledge. He distinctly notices individual physiognomy, national physiognomy, and comparative physiognomy. The state of knowledge in his time did not admit of a complete elucidation of his general principles; on that account his enumeration of particular observations and precepts is by no means so well founded or so accurate as his method of study. Even his style, concise and energetic, was inimical to the subject; which, to be made clearly comprehensible, must require frequent paraphrases. Aristotle's performance, however, such as it is, has been taken as the groundwork and model of every physiognomical treatise that has since appeared.

The imitators of this great man in the 16th and 17th centuries have even copied his language and manner, which are sententious, indiscriminate, and obscure. His comparative physiognomy of men with beasts has been frequently though not universally adopted. Besides his treatise expressly on the subject, many incidental observations on physiognomy will be found interspersed through his other works, particularly in his history of animals.

Next after Aristotle, his disciple and successor Theophrastus deserves to be particularly mentioned as a writer on the subject in question. His ethic characters, a singular and entertaining performance, composed at the age of 99, form a distinct treatise on a most important branch of physiognomy, the physiognomy of manners: but the translations and imitations of La Bruyere are so excellent, that by referring to them we do greater justice than would otherwise be in our power, both to Theophrastus and to our readers. We cannot, however, omit observing, that the accuracy of observation and liveliness of description displayed in the work of Theophrastus will preserve it high in classical rank, while the science of man, and the prominent characteristics of human society, continue to be objects of attention.

Polemon of Athens, Adamantius the sophist, and several others, wrote on the subject about the same period. Lately there has been published a collection of all the Greek authors on physiognomy; the book is entitled, *Physiognomiaz veteris Scriptores Græci. Gr. et Lat. a Franzio Altenb. 1780, 8vo.* From the number of these authors, it appears that the science was much cultivated in Greece; but the professors seem soon to have connected with it something of the marvellous, and especially with the art of divination.

From this period to the close of the Roman republic, nothing worthy of remark occurs in the literary history of physiognomy. About the last-mentioned era, however, and from thence to the decline of the empire under the later emperors, the science appears to have been

P H Y S I O G N O M Y.

cultivated as an important branch of erudition, and assumed as a profession by persons who had acquired a superior knowledge in it.

In the works of Hippocrates and Galen, many physiognomical observations occur. Cicero appears to have been peculiarly attached to the science. In his oration against Piso, and in that in favour of Roscius, the reader will at the same time perceive in what manner the orator employs physiognomy to his purposes, and find a curious instance of the ancient manner of oratorical abuse.

Many physiognomical remarks are to be found likewise in the writings of Sallust, Suetonius, Seneca, Pliny, Aulus Gellius, Petronius, Plutarch, and others.

That in the Roman empire the science was practised as a profession, ample evidence appears in the writings of several of the authors just mentioned. Suetonius, for instance, in his life of Titus, mentions that Narcissus employed a physiognomist to examine the features of Britannicus, who predicted that Britannicus would not succeed, but that the empire would devolve on Titus.

The science of physiognomy shared the same fate with all others, when the Roman empire was overthrown by the northern barbarians. About the beginning of the sixteenth century it began again to be noticed. From that time till the close of the seventeenth, it was one of the most fashionable studies. Within that space have appeared almost all the approved modern authors on the subject. See the Polyhistor of Morhoff. I. i. 15; and II. iii. 1.

It is unfortunate for physiognomy, that by many of these writers it has been held to be connected with doctrines of which the philosophy of the present day would be ashamed. With these doctrines it had at one time almost sunk into oblivion.

In every period of the history of literature there may easily be marked a prevalence of particular studies. In the early period, for instance, of Grecian literature, mythological morality claimed the chief attention of the philosophers. In the more advanced state of learning in Greece and in Rome, poetry, history, and oratory, held the pre-eminence. Under the later emperors, and for some time afterwards, the history of theological controversies occupied the greatest part of the works of the learned. Next succeeded metaphysics, and metaphysical theology. These gave place to alchemy, magic, judicial astrology, the doctrine of signatures and sympathies, the mystic, theosophic, and Rosicrucian theology, with physiognomy. Such were the pursuits contemporary with the science which is the object of our present inquiry. It is no matter of surprise, that, so associated, it should have fallen into contempt. It is not unusual for mankind hastily to reject valuable opinions, when accidentally or artificially connected with others which are absurd and untenable. Of the truth of this remark, the history of theology, and the present tone of theological opinions in Europe, furnish a pregnant example.

To physiognomy, and the exploded sciences last mentioned, succeeded classic philology; which gave place to modern poetry and natural philosophy; to which recently have been added the studies of rational theology, chemistry, the philosophy of history, the history of man, and the science of politics.

About the commencement of the eighteenth century, and thence forward, the occult sciences, as they are termed, had declined very considerably in the estimation of the learned; and those who treated of physiognomy forbore to disgrace it by a connection with those branches of ideal learning with which formerly it had been invariably conjoined. In Britain, Dr. Gwyther noticed it with approbation. His remarks are published in the Philosophical Transactions, vol. xviii. and Dr. Parsons chose it for the subject of the Croonian lectures, published at first in the second supplement to the 44th volume of the Philosophical Transactions, and afterwards (1747) in a separate treatise, entitled Human Physiognomy explained.

The observations, however, of these writers, as well as of Lancisius, Haller, and Buffon, relate rather to the transient expression of the passions than to the permanent features of the face and body. The well-known characters of Le Brun likewise are illustrative of the transient physiognomy, or (as it is termed) pathognomy. See PASSIONS in PAINTING.

During the present century, although physiognomy has been now and then attended to, nothing of importance appeared on the subject till the discussion between Pernetty and Le Cat, in the Berlin Transactions. Their essays are employed in discussing the following questions: 1. Whether it would or would not be advantageous to society, were the character, disposition, and abilities, of each individual so marked in his appearance as to be discovered with certainty?

2. Whether, on the supposition that by the highest possible proficiency in physiognomy we could attain a knowledge in part only of the internal character, it would be advantageous to society to cultivate the study, mankind being in general imperfect physiognomists?

No reasoning *a priori* can possibly determine these questions. Time and experience alone must ascertain the degree of influence which any particular acquisition of knowledge would have on the manners and characters of mankind; but it is difficult to conceive how the result of any portion of knowledge, formerly unknown, and which mankind would be permitted to discover, could be any thing but beneficial.

Soon after this controversy in the Berlin Transactions, appeared the great work of M. Lavater, dean of Zurich, which has excited no inconsiderable portion of attention in the literary world. The work itself is magnificent: that circumstance, as well as the nature of the subject which was supposed to be fanciful, have contributed to extend its fame; and certainly, if we may judge, the book, though many faults may be detected in it, is the most important of

any that has appeared on the subject since the days of Aristotle. Lavater professes not to give a complete synthetical treatise on physiognomy, but, aware that the science is yet in its infancy, he exhibits fragments only illustrative of its different parts. His performance is no doubt desultory and unconnected. It contains, however, many particulars much superior to any thing that had ever before appeared on the subject.

With the scholastic and systematic method adopted by the physiognomists of the last and preceding centuries, Lavater has rejected their manner of writing, which was dry, concise, indeterminate, and general: his remarks, on the contrary, are for the most part precise and particular, frequently founded on distinctions extremely acute. He has omitted entirely (as was to be expected from a writer of the present day) the astrological reveries, which deform the writings of former physiognomists; and he has with much propriety deduced his physiological observations but seldom from anatomical or physiological reasoning. Such reasoning may perhaps at some future period become important; but at present our knowledge of facts, although extensive, is not so universal as to lay a stable foundation for particular deductions. Lavater has illustrated his remarks by engravings; a method first adopted by Baptista Porta. Lavater's engravings are very numerous, often expressive, and tolerably executed.

The opinions of this celebrated physiognomist are evidently the result of actual observation. He appears indeed to have made the science his peculiar study, and the grand pursuit of his life. His performance exhibits an extended comprehension of the subject, by a particular attention to osseal physiognomy, and the effect of profiles and contours. His style in general is forcible and lively, although somewhat declamatory and digressive. His expressions are frequently precise, and strikingly characteristic; and the spirit of piety and benevolence which prevades the whole performance renders it highly interesting.

The defects of the work, however, detract much from the weight which Lavater's opinions might otherwise challenge. His imagination has frequently so far outstript his judgment, that an ordinary reader would often be apt to reject the whole system as the extravagant reverie of an ingenious theorist. He has clothed his favourite science in that affected mysterious air of importance which was so usual with his predecessors, and describes the whole material world to be objects of the universal dominion of physiognomy. He whimsically conceives it necessary for a physiognomist to be a well-shaped handsome man. He employs a language which is often much too peremptory and decisive, disproportioned to the real substance of his remarks, or to the occasion of making them. The remarks themselves are frequently opposite in appearance to common observation, and yet unsupported by any illustrations of his.

Lavater certainly errs in bestowing too great a reliance on single features, as the foundation of decision on character. His opinions on the physiognomy of the ears, hands, nails, and feet, of the human species, on hand-writing, on the physiognomy of birds, insects, reptiles, and fishes, are obviously premature, as hitherto no sufficient number of accurate observations have been made, in regard to either of these particulars, to authorise any conclusion. He has erred in the opposite extreme, when treating of the important topic of national physiognomy, where he has by no means prosecuted the subject so far as facts might have warranted. We must farther take the liberty to object to the frequent introduction of the author's own physiognomy throughout the course of his work. His singular remarks on his own face do not serve to prejudice the reader in favour of his judgment, how much soever his character may justify the truth of them. We must regret likewise, for the credit of the science, that the author's singularly fanciful theory of apparitions should so nearly resemble a revival of the antiquated opinions of the sympathists.

To these blemishes, which we have reluctantly enumerated, perhaps may be added that high impassioned tone of enthusiasm in favour of his science every where displayed throughout the work of this author, which is certainly very opposite to the cool patient investigation befitting philosophy. To that enthusiasm, however, it is probable that in this instance (as is, indeed, no unrequent effect of enthusiasm) we are indebted for the excellency which the author has attained in his pursuit; and it possesses the salutary tendency of putting us on our guard against a too implicit acquiescence in his physiognomical decisions.

In the Berlin Transactions for 1775, there appears a formal attack upon Lavater's work by M. Formey. After disputing the propriety of the extensive signification applied by Lavater and Pernetty to the term physiognomy, M. Formey adopts nearly the definition which we conceive to be the most proper. He allows that the mental character is intimately connected with, and sensibly influenced by, every fibre of the body; but his principal argument against physiognomy is, that the human frame is liable to innumerable accidents, by which it may be changed in its external appearance, without any correspondent change of the disposition; so that it surpasses the extent of the skill of mortals to distinguish the modifications of feature that are natural from those which may be accidental. Although, therefore, the science of physiognomy may be founded in truth, he infers that the Deity only can exercise it.

M. Formey further contends, that education, diet, climate, and sudden emotions, nay even the temperaments of ancestors, affect the cast of human features; so that the influence of mental character on these features may be so involved with, or hidden by, accidental circumstances, that the study of physiognomy must ever be attended by hopeless uncertainty.

PHYSIOGNOMY.

These objections are worthy of notice, but they are by no means conclusive.

We shall give a specimen of M. Lavater's manner of treating the subject on the opposite side of the question: a specimen not in Lavater's precise words, but conveying more shortly an idea at once of his sentiments, and of his manner of expressing them.

No study, says he, excepting mathematics, more justly deserves to be termed a science than physiognomy. It is a department of physics, including theology and belles lettres, and in the same manner with these sciences may be reduced to rule. It may acquire a fixed and appropriate character; it may be communicated and taught.

Truth or knowledge, explained by fixed principles, becomes science: Words, lines, rules, definitions, are the medium of communication. The question, then, with respect to physiognomy will thus be fairly stated. Can the striking and marked differences which are visible between one human face, one human form, and another, be explained, not by obscure and confused conceptions, but by certain characters, signs, and expressions? Are these signs capable of communicating the vigour or imbecility, the sickness or health, of the body; the wisdom, the folly, the magnanimity, the meanness, the virtue, or the vice, of the mind?

It is only to a certain extent that even the experimental philosopher can pursue his researches. The active and vigorous mind, employed in such studies, will often form conceptions which he shall be incapable of expressing in words, so as to communicate his ideas to the feebler mind, which was itself unable to make the discovery: but the lofty, the exalted mind, which soars beyond all written rule, which possesses feelings and energies reducible to no law, must be pronounced unscientific.

It will be admitted, then, that to a certain degree physiognomical truth may as a science be defined and communicated. Of the truth of the science there cannot exist a doubt. Every countenance, every form, every created existence, is individually distinct, as well as different, in respect of class, race, and kind. No one being in nature is precisely similar to another. This proposition, in so far as regards man, is the foundation-stone of physiognomy. There may exist an intimate analogy, a striking similarity between two men, who yet being brought together, and accurately compared, will appear to be remarkably different. No two minds perfectly resemble each other. Now, is it possible to doubt that there must be a certain native analogy between the external varieties of countenance and form and the internal varieties of the mind? By anger the muscles are rendered protuberant: are not, then, the angry mind, and the protuberant muscles, as cause and effect? The man of acute wit has frequently a quick and lively eye. Is it possible to resist the conclusion, that between such a mind and such a countenance there is a determinate relation?

Every thing in nature is estimated by its

physiognomy; that is, its external appearance. The trader judges by the colour, the fineness, the exterior, the physiognomy of every article of traffic; and he at once decides that the buyer "has an honest look," or "a pleasing or forbidding countenance."

That knowledge and science are detrimental to man, that a state of rudeness and ignorance is preferable, and productive of more happiness, are tenets now deservedly exploded. They do not merit serious opposition. The extension and increase of knowledge, then, is an object of importance to man: and what object can be so important as the knowledge of man himself? If knowledge can influence his happiness, the knowledge of himself must influence it the most. This useful knowledge is the peculiar province of the science of physiognomy. To conceive a just idea of the advantages of physiognomy, let us for a moment suppose that all physiognomical knowledge were totally forgotten among men; what confusion, what uncertainty, what numberless mistakes would be the consequence! Men destined to live in society must hold mutual intercourse. The knowledge of man imparts to this intercourse its spirit, its pleasures, its advantages.

Physiognomy is a source of pure and exalted mental gratification. It affords a new view of the perfection of Deity: it displays a new scene of harmony and beauty in his works; it reveals internal motives, which without it would only have been discovered in the world to come. The physiognomist distinguishes accurately the permanent from the habitual, the habitual from the accidental, in character. Difficulties, no doubt, attend the study of this science. The most minute shades, scarcely discernible to the unexperienced eye, denote often total opposition of character. A small inflexion, diminution, lengthening or sharpening, even though but of a hair's breadth, may alter in an astonishing degree the expression of countenance and character. How difficult then, how impossible indeed, must this variety of the same countenance render precision! The seat of character is often so hidden, so masked, that it can only be detected in certain, perhaps uncommon, positions of countenance. These positions may be so quickly changed, the signs may so instantaneously disappear, and their impression on the mind of the observer, may be so slight, or these distinguishing traits themselves so difficult to seize, that it shall be impossible to paint them or describe them in language. Innumerable great and small accidents, whether physical or moral, various incidents and passions, the diversity of dress, of position, of light or shade, tend to display the countenance often in so disadvantageous a point of view, that the physiognomist is betrayed into an erroneous judgment of the true qualities of the countenance and character. Such causes often occasion him to overlook the essential traits of character, and to form a decision on what is purely accidental. How surprisingly, for instance, may the smallpox disfigure the countenance, and destroy or confound, or render

imperceptible, traits otherwise the most decisive!

We shall then, continues Lavater, grant to the opposer of physiognomy all he can ask; and yet we do not live without hopes that many of the difficulties may be resolved which at first appeared inexplicable.

He then proceeds to a specific illustration of his subject under a great variety of titles, in which he treats of human nature in general, and of each particular feature separately.

To enumerate the different divisions of his book would not be more satisfactory to our readers than the perusal of the contents of the book itself: and an attempt to epitomise even the essential substance of the vast multiplicity of matter contained in his essays (which are yet only fragments, and to which indeed he himself does not pretend to give any higher appellation), would extend this article to a disproportionate length. Such an abridgement, after all, would convey no solid information on a subject which merits all the time and study that an attentive perusal of Lavater's works at large would require.

From the historical deduction of the literary progress of physiognomy which we have thus attempted to lay before our readers, it appears, that although the science has fallen into disrepute, there can scarcely be mentioned a period in which any cultivation of science took place when physiognomy was not likewise the study, nay sometimes even the profession, of men of the most eminent abilities and the greatest learning.

The reasons why at present so little attention is paid to the subject probably are,

1. That it has been treated in conjunction with subjects now with propriety exploded: and,

2. That it has been injured by the injudicious assertions and arguments of those who have undertaken its defence.

Sometimes, however, the wise and the learned may err. The use of any thing must not be rejected for no better reason than that it is capable of abuse. Perhaps the era is not distant when physiognomy shall be reinstated in the rank which she merits among the valuable branches of human knowledge, and be studied with that degree of attention and perseverance which a subject deserves so essentially connected with the science of man.

That there is an intimate relation between the dispositions of the mind and the features of the countenance is a fact which cannot be questioned. He who is sinking under a load of grief for the death of an affectionate wife or a dutiful child, has a very different cast of features from the man who is happy in the prospect of meeting his mistress. A person boiling with anger has a threatening air in his countenance, which the most heedless observer never mistakes; and if any particular disposition be indulged till it become habitual, there cannot be a doubt that the corresponding traces will be so fixed in the face as to be discernible by the skilful physiognomist, under every effort

made to disguise them. But when we attempt to decide on a man's intellectual powers by the rules of this science, we are often deceived: and in this respect we have reason to believe that Lavater himself has fallen into the grossest mistakes.

The latest popular attempt at any department of this science was that of Dr. Gall of Vienna, in his lectures on what he chose to denominate craniology, although he affected to be displeased at every attempt to connect his own peculiar study with that of physiognomy. The theory of this learned but as it appears to us extravagant philosopher endeavoured to account for every variety of habit or of feeling, and in reality for all the animal senses of every kind both external and internal, by supposing some particular part of the brain to be allotted to each peculiarity, and that the general character and temper of the individual is the result of the different proportions which these different parts or chambers of the brain bear to one another. He supposes also that this organ is possessed of two distinct sets of nervous fibres, a secretant and an absorbent; both directly connected with what is called the cineritious or ash-coloured department of the brain; the former issuing from it and secreting the fluid of the will, or that by which the mind operates on the muscles; and the latter rather terminating in it, and conveying to it the fluid of the external senses, secreted by those senses themselves, and communicating a knowledge of the presence and degree of power of external objects. This elaborate theory and the facts to which it appeals were very minutely investigated about three or four years ago, by a very excellent committee of the physical class of the French National Institute, assisted by M. Spurzheim, the most intimate friend and co-adjutor of the inventor; who, after a very minute and cautious research, gave it as a part of their report that the doctrine of the origin and action of the nerves is probably correct; but that this doctrine does not appear to have any immediate or necessary connection with that part of Dr. Gall's theory which relates to distinct functions possessed by distinct parts of the brain. In refutation, however, of this last part of the theory it will only be sufficient to observe, that while many of the nerves productive of various functions originate in the same part of the brain, others confined to the same function originate in various parts. Thus the cerebrum, which gives birth to the olfactory and ophthalmic nerves, gives birth also to the oculorum motorii; the cerebellum gives birth to both the trochleatores and the trigemini; and the medulla oblongata to the auditory, the par vagum and the lingual. For more on this subject, see CRANIOGNOMY.

PHYSIOLOGICAL. *a.* (from *physiology*.) Relating to the doctrine of the natural constitution of things (*Boyle*).

PHYSIOLOGIST. *s.* (from *physiology*.) A writer of natural philosophy.

PHYSIOLOGY. (*φυσικη*, nature, and *λογος*, doctrine, science, or treatise.) The science of na-

ture; physics; natural philosophy; the philosophy of physics or of nature.

Such is the literal meaning of the word; and such was, at one time, the subject it was employed to designate. As the terms natural history, however, have been of late years limited to the history of organized nature, physiology has, in like manner, been limited to the philosophy of natural history, in the same restricted sense; and is now commonly used to import general or synthetical views of organized life, whether in regard to plants or animals; and is occasionally, indeed, confined to those of animals alone.

To controvert the erroneous use of a term is the purport of the etymologist, the grammarian, and the critic, but not of the editor of a dictionary of arts and sciences. We are therefore compelled to take the word in the common, though erroneous, sense in which we find it in the present day, and shall consider it as simply referring to the more important phenomena of vegetable and animal life.

Vegetable Physiology.

The best writers in the present day upon this subject as a whole are M. Wildenow, M. Mirbell, and Dr. Smith: besides whom, there are many others that have touched upon particular parts with great advantage, and among these it would be unjust not to mention the names of Dr. Darwin, Mr. Knight, and Mr. Ellis. We must, in as few words as we can, give the general result of their separate pursuits and observations. Plants and animals are equally the progeny of seeds: there are other modes of production to be met with perhaps in both instances, as those of buds and bulbs, of slips and cuttings, but the common mode belonging to both is that of semination.

The seed is sometimes naked, but more generally covered with a pericarp, whence plants become naturally divided into the two grand classes of gymnospermous, and angiospermous. The pericarp is of various forms and structures; and of these the more common are the legume, silique, or siliqua, being merely varieties of what, among ourselves, is denominated in popular language, pod or pod; the loment, which is a kind of pod not so frequent as either of the former, but of which we have an instance in the mimosas and cassia fistula, the pome or core-apple, of which we have instances in the common-apple, and the orange; the drupe, or stone-apple, instances of which occur to us in the plum, cherry, and almond; the glume or chaff; the berry; the acinus or conglomerate berry, as in the rasp; the nut; and the capsule.

Stripping off this outer covering, we find the seed to consist internally of a coraculum, corcle, or little heart, and externally of a parenchymatous substance surrounded with a double integument, sometimes single, sometimes bifid, and sometimes more than bifid, and hence denominated monocotyledonous, dicotyledonous, polycotyledonous; in plain English, seed-lobes, or seed-leaves, single, double, or more than double. It was very generally supposed formerly, and is still supposed by some botanists, that the seeds of various orders of plants, as the mosses, fungi, and algae, are acotyledonous, or totally destitute of a cotyledon of any kind. But as many, perhaps most plants of this kind have of late been discovered to possess some such parenchyma, we have great reason to believe that this organ is universal, and that there is no such thing as an acotyledonous seed in the whole

vegetable kingdom. In reality the cotyledon appears absolutely necessary for the germination and future growth of the seed, and may hence be denominated its lungs or placental. Like the perfect plant, it possesses lymphatics and air-vessels. Through the former of these it absorbs the moisture of the soil into which it is plunged, decomposes a part of it into its elementary principles, and conducts those principles together with the undecomposed water to the corcle, which becomes stimulated to the process of germination by the oxygen thus set at liberty; while through the latter it breathes forth its excess of oxygen, together with a considerable portion of carbonic acid, and hydrogen gasses, and generally some portion of azot.

It is the corcle, then, which is the true punctum saliens of vegetable life, and to this the cotyledon is subservient. The corcle consists of two parts, an ascending and a descending; the former called its plumule, which gives birth to the trunk and branches, the latter denominated its rosetel, which gives birth to the root and radicles. The position of the corcle in the seed is always in the vicinity of the hilum or eye, which is a cicatrix or umbilicus, remaining after the separation of the funis or umbilical cord from the pericarp to which the seed has hereby been attached. The first radicle or germinating branch of the rosetel uniformly elongates, and pushes into the earth, before the plumule evinces any change: like the cotyledon, the radicles consist chiefly of lymphatics and air-vessels, which serve to separate the water from the soil, in order that the oxygen may be separated from the water.

Hence originates the root, unquestionably the most important part of the plant, and which, in some sense, may be regarded as the plant itself: for if every other part of the plant be destroyed, and the root remain uninjured, this organ will regenerate, and the whole plant be renewed; but if the root perish, the plant becomes lost irrecoverably. Yet there are various phenomena in vegetable life that manifest a smaller difference in the nature of the root and the trunk, than we should at first be induced to suppose; for in several species, and especially those of the prunus and salix tribes, if the stem branches be bent down to the earth, plunged into it, and continued in this situation for a few months, these branches will throw forth radicles; and if, after this, the original root be dug up, and suffered to ascend into the air, so that the whole plant become completely inverted, the original root will throw forth stem-branches, and bear the wild fruit peculiar to its tribe. The rhizophora, mangle or mangrove-tree, grows naturally in this manner; for its stem-branches, having reached a certain perpendicular height, bend downwards of their own accord, and throw forth root-branches into the soil, from which new trunks arise, so that it is not uncommon, in some parts of Asia and Africa, to meet with a single tree of this species covering the oozy waters in which it grows, with a forest of half a mile in length.

The solid parts of the trunk of the plant consist of cortex, cuticle, or outer bark, liber, cutis, or inner bark, albumen, or soft wood, lignum, or hard wood, and medulla, or pith. Linnæus gave the name of medulla to the pith of plants, upon a supposition that it had a near resemblance to the medulla spinalis of quadrupeds. A closer investigation, however, has since proved, that this resemblance is very faint, and that the pith or medulla

of vegetables consists of nothing more than a mere spongy cellular substance, forming indeed an admirable reservoir for moisture; and hence of the utmost importance to young plants, which, in consequence of their want of leaves and branches whose surfaces are covered with the bibulous mouths of innumerable lymphatics, would otherwise be frequently in danger of perishing through absolute drought; but gradually of less use as the plant advances in age, and becomes possess of these ornamental appendages; and hence, except in a few instances, annually encroached upon, and at length totally obliterated by the surrounding lignum.

All these lie in concentric circles, and the trunk enlarges, according to the theory of Grew and Malpighi, by the formation of a new liber or inner bark every year; the whole of the liber of one year, excepting indeed its outermost layer, which is transformed into cortex, becoming the alburnum of the next, and the alburnum becoming the lignum: but according to Mr. Knight's recent and very ingenious and well supported theory, it enlarges by an annual transfer of a layer of the preceding year's alburnum into a state of wood, a new layer being formed every year to take the place of that which is thus transferred. Whence it is obvious, that a mark of any kind which has penetrated through the outer into the inner bark, must in a long process of years be comparatively transferred to the central parts of the trunk; on which account we often find in felling trees of great longevity, as the oak, for example, the date of very remote national æras, and the initials of monarchs who flourished in very early periods of our national history, stamped in the very heart of the timber on its being subdivided.

As these series of concentric circles, moreover, produced by the growth of every year, are still visible after the conversion of every other part into lignum or hard wood, we can trace the age of a tree, with a considerable degree of certainty, by allowing a year for every outer circle, and about two or three years for the complete lignification of the innermost.

Independently of these more solid parts of the trunk or stem, we generally meet with some portion of parenchyma and cellular substance, and always with the different systems of vegetable vessels disposed in one common and uniform arrangement. The lower orders of plants, indeed, such as the annuals and biennials, consist almost exclusively of parenchyma or cellular substance, with an inner and outer bark, and the respective vessels of the vegetable system.

These vessels are adducent and reducent, or arteries and veins, pneumatic or air-vessels, and lymphatics. The lymphatics lie immediately under the cuticle and in the cuticle. They anastomose in different ways through their minute intermediate branches, and, by surrounding the apertures of the cuticle, perform the alternating economy of inhalation and exhalation. Their direction varies in different species of plants, but is always uniform in the same species.

Immediately below these lie the adducent vessels or arteries; they are the largest of all the vegetable vessels, rise immediately from the root, and communicate nutriment in a perpendicular direction; and when the stem of a plant is cut horizontally they instantly appear in circles. Interior to these lie the reducent vessels or veins, which are softer, more numerous, and more minute than the arteries, and in young shoots run down

through the cellular texture and the pith. Between the arteries and veins are situated the air-vessels as they were formerly called, but which Dr. Darwin and Mr. Knight have sufficiently succeeded in proving to contain not air in their natural state, but sap. They are delicate membranous tubes stretching in a spiral direction, the folds being sometimes close to each other and sometimes more distant, but generally growing thicker towards the root, and especially in ligneous plants. These vessels also are very minute, and according to numerous observations of Hedwig made with the microscope, seldom exceed a 290th part of a line, or a 3000th part of an inch in diameter.

The lymphatics of a plant may be often seen with great ease by merely stripping off the cuticle with a delicate hand, and then subjecting it to a microscope; and in the course of the examination we are also frequently able to trace the existence of a great multitude of valves, by the action of which the apertures of the lymphatics are commonly found closed. Whether the other systems of vegetable vessels possess the same mechanism, we have not been able to determine decisively; the following experiment, however, should induce us to conclude that they do. If we take the stem of a common balsamine, or of various other plants, and cut it horizontally at its lower end, and plunge it, so cut, into a decoction of Brazil wood, or any other coloured fluid, we shall perceive that the arteries or adducent vessels, as also the air-vessels, will become filled or injected by an absorption of the coloured liquor, but that the veins, or reducent vessels, will not become filled; of course evincing an obstacle, in this direction, to the ascent of the coloured fluid. But if we invert the stem, and in like manner cut horizontally the extremity which till now was uppermost, and plunge it so cut into the same fluid, we shall then perceive that the veins will become injected, or suffer the fluid to ascend, but that the arteries will not; proving clearly the same kind of obstacle in the course of the arteries in this direction, which was proved to exist in the veins in the opposite direction, and which reverse obstacles we can scarcely ascribe to any other cause than the existence of valves.

By this double set of vessels, moreover, possess of an opposite power, and acting in an opposite direction, the one to convey the sap or vegetable blood forwards, and the other to bring it backwards, we are able very sufficiently to establish the phenomenon of a circulatory system, and, according to several of the experiments of M. Willdenow, it seems probable that this circulatory system is maintained by the projectile force of a regular and alternate contraction and dilatation of the vegetable vessels. Yet the great minuteness of these vessels must ever render it extremely difficult to obtain any thing like absolute certainty upon this subject. Nor could we establish the fact should we by any means be able to determine the cause of their propulsive or contractile power; for no experiments hitherto made have proved vegetables of any kind, even the most irritable of them, as the mimosas, the drosera, the hedyasrum gyrans, to be possessed of any thing like muscularity of fibre. Grew ascribed the ascent of the sap to its levity as though acting with the force of vapour; Malpighi to an alternate contraction or dilation of the air contained in what he erroneously conceived to be air-vessels, and which now appear to be nutritive vessels; Perrault to fermentation;

PHYSIOLOGY.

Hales and Tournefort to capillary attraction: not one of which theories however will better explain the fact than another, as Dr. Thomson has very ably established, *Chem. V.* 388; as he has also the probability of the existence of a contractile power from some cause or other in the different sets of vegetable vessels.

In what part of a plant the vital principle chiefly exists, or to what quarter it retires during the winter, we know not: but we are just as ignorant in respect to animal life. In both it operates towards every point; it consists in the whole, and resides in the whole; and its proof of existence is drawn from its effecting almost every one of its functions and combinations in direct opposition to the laws of chemical affinity, which would otherwise as much control it as they control the mineral world, and which constantly assume an authority as soon as ever the vegetable is dead. Hence the plant thrives and increases in its bulk, puts forth annually a new progeny of buds, and becomes clothed with a beautiful foliage of lungs, every leaf being a distinct lung of itself, for the respiration of the rising brood; and with an harmonious re-action that can never be too much admired, inhales for its support, from the surrounding atmosphere, the carbonic acid gas which is irrespirable by animals, and throws forth the pure oxygen on which animal respiration depends.

Animal Physiology.

The approach from vegetable to animal life is by shades, almost, and sometimes altogether, imperceptible. Even that ammoniacal smell which has been conceived to be chemically characteristic of the former origin, is given forth by the clavaria and several other funguses: nor is it long since this genus was actually regarded as a zoophyte, while to this hour it remains in Millar arranged along with the corals and corallines.

Generally speaking, however, and with respect to all the more perfect and elaborate kinds, we may observe that while the principle of life in vegetables evinces no other powers that can be fairly traced than those of irritability and contractility, it superadds to these, in animals, the higher powers of muscularity, sensation, and consciousness.

Animal physiology is a science as yet in its infancy, though from the antiquity of its birth it might have been expected long ere now to have made a much greater progress towards maturity. Many circumstances, however, have checked its growth, and not a few derived from general science itself, and which were started with a view of accelerating its progress. Such more especially have been the fond and sickening favouritisms that have been bestowed upon it by almost every branch of science in its turn. It was once almost killed by the kindness of the metaphysicians, and was afterwards as nearly destroyed by the dandling of the mechanical philosophers; nor has it been put in the right track, or given proofs of any thing like healthful vigour, or a promise of maturity, till assisted by the discoveries of chemistry, and the labours of the comparative anatomist.

To the first of these it is very essentially and very extensively indebted, and it may literally be said to have

Grown with its growth and strengthened with its strength.

From a small beginning, and from modestly professing to observe merely the different phenomena which are the effects of heat and mix-

ture, chemistry has risen, like astronomy, to the first eminence among the sciences. By its numerous researches it has found widely diffused over nature a variety of singularly active bodies, which have been generally called salts. Of these salts it has noticed some which change a blue vegetable tincture into green, and others which change that tincture into red: the former of these it has called alkalis, and the latter are known by the name of acids. It has observed, that when acids and alkalis are brought into contact, and either of them nearly in a fluid state, they encounter with violence effervescence and heat, and form a salt, which, being neither acid nor alkaline, is called neutral. It has been remarked that all these salts, whether volatile or fixed, whether fluid or concrete, have each permanently uniform characters; and that, though sometimes blended in a mixture, or made to vanish in a solution, yet, when they are separated, they resume their taste, their smell, their colour, and their form, and exhibit as before the same power in dissolving earths, metals, and stones, and in making inflammable bodies to smoke, to kindle, and explode with a loud noise. All, however, act not alike upon all bodies; those acids which dissolve iron remain quite harmless upon gold. And chemistry here has been led to observe that particular salts show a preference for particular bodies, that there is in them an appearance of choice, and that their character is never to be known but by studying their different elective attractions.

Besides salts, chemistry of late has also discovered a number of bodies that are still more wonderful, still more active, and some of them at least still more widely diffused over nature. These are certain aeriform fluids which are called gasses: these gasses, like the mind itself, are discernible only by their effects; all are elastic, and all are combined with the principle of heat. Their kinds are various; some are inflammable, some are saline and soluble in water, some are neither the one nor the other, and some distinguished by the name of airs, maintaining combustion and respiration: their importance is such, that there is not a single process in chemistry, nor perhaps one regular process in nature, in which the phenomena of the disengagement or fixation of heat, and the disengagement or fixation of elastic fluids, are not observed either separately or together. Two of these fluids compose water, two the nitric acid, two ammonia, and three of them are found in atmospheric air; one of them has been plausibly thought to be the alkaligenous principle in bodies, and two of them to be the constituents of oil: the principle of acidity is sufficiently ascertained to be one of the two which compose water. The same fluid oxydates metals, supports flame during combustion, communicates heat to the circulating blood, and maintains life in the act of respiration.

Such are a few of the general and admitted phenomena; and to which we must adhere till the later experiments have been more completely established, and the theories which have originated from them are divested of their doubts.

By that knowledge which it thus has acquired of salts and of gasses, by its more ingenious modes of analysis, and by some discoveries which it has made concerning the nature of heat and of light, chemistry is now able to account for many phenomena that before were inexplicable. In France particularly it has been recently extending its researches with a good deal of ardour towards the phenomena of both the animal and vegetable

PHYSIOLOGY.

kingdoms: it has there found its salt and its gasses, its heat and its light, active and busy.

It is more than a century since it observed that plants were nourished by pure water and atmospheric air; that from these alone they derived their extracts, their mucilage, their oil, their coal, their acids, their alkalis, and aroma. But since the discovery of different kinds of elastic fluids, it has farther remarked, that they grow rapidly in hydrogenous gass, and in air mixed with carbonic acid; that assisted by light their leaves absorb hydrogen from water, carbon from the acid of which they are so fond; and, thus decomposing the one and the other, disengage from both the oxygenous principle, or vital air, and restore to the atmosphere salubrity and health.

Leaving vegetables, which, by analysis in close vessels and in red-hot pipes, it has reduced to hydrogen, oxygen, azot, and charcoal, it has made discoveries no less important in the animal kingdom. It has found that the food of the nobler animals, which immediately or remotely is prepared by vegetables, is generally acted upon by a solvent: it has proved by experiment, that the animal organs can fix azot; can decompose atmospheric air; can form lime, iron, and carbonic acid, as well as vegetables, produce a number of saline substances, which no art could detect in their food. Nor is it here that such discoveries are meant to terminate; these seemingly creative powers of vegetation and of animalization, with other phenomena in the structure and economy of living bodies, chemistry imagines that it will yet be able to explain. We may safely venture, however, to predict, that something more than its present knowledge of the various effects of heat and of mixture will in this case be found necessary to ensure success. The late discovery of elastic fluids and their singular properties affords the strongest reasons to suspect that we yet may be ignorant of many agents which nature employs in the functions of bodies. But whatever be the truth, we are almost certain that these agents discovered by the chemists are not alone concerned. Electricity, magnetism, and what have been called animal electricity and animal magnetism, must not be excluded from acting some part. The growth of plants, it is well known, is considerably affected by the electrical state of the atmosphere; it is sensibly promoted by a proper use of the vegeto-electrometer, and has been said to indicate a difference between the negative and positive electricities, whether these be kinds or states of the fluid. Such too is our present knowledge, that electricity as yet seems the only cause to which we can ascribe the seeming chemical affinities of the dew; its constant practice in avoiding some bodies, its predilection for others, and particularly its attachment to the living points of plants and of leaves: nor is this electricity wholly unconnected with the animal kingdom; when we think of its singular fondness for points, it occurs that one intention of our hairs may probably have been to collect and diffuse it. It is plainly excited in cross rubbing the hair of some animals; and when we wear silk, it is frequently accumulated upon the surface of our own bodies.

The iron found in plants and in animals is certainly somewhat of a striking circumstance, and cannot be denied to be one reason why magnetism should not be wholly overlooked.

As for animal electricity, or what has been called so, it is now, we believe, generally allowed to hold an important place in the system. It is

very perceptible in all those nerves which are subservient to voluntary motions; nor is it limited to these alone. In several instances where metals were applied to the nerves of the heart, which nature has destined to spontaneous motions, they were seen to awaken the dormant powers in the muscular fibres of that viscus. We here speak only of the nerves; but the torpedo, the gymnotus electricus, and silurus electricus, possess a particular structure of organs for collecting this fluid, for discharging it at pleasure, and for giving a shock. If those who are accustomed to the common kind of electrical experiments may at first be surprised that this electric fluid in the animal is not discharged from the nerves by water, or any other metallic conductor that is pure and unmixed, another fact, which is fully as striking, though it has not been hitherto mentioned by any observer known to us, appears to merit equal attention: Cut away the leg of a frog, uncover a part of the crural nerve, place the limb now on a table on which an electrifying machine is working, you will see the muscles strongly convulsed at every spark which you draw from the conductor, but remaining motionless upon the discharge of the Leyden phial.

The aid which anatomy affords to physiology is next to be considered. Physiology in general and the study of anatomy are so closely connected, that, as Haller imagined, they can hardly be separated even in idea. In his opinion, the man who should attempt to become a physiologist without anatomy, would act as wisely as the mathematician who, without seeing the wheels or the pinions, or without knowing the size, the proportions, or the materials of any machine, would yet presume from mere calculation to determine its powers, its properties, and uses. In this comparison, the importance of anatomy, we are really persuaded, is not represented in a light too strong; nor does that medium through which it has been viewed appear to have been magnified beyond nature.

Whether art or science, anatomy is one of those eminent accomplishments without which no one is able to prosecute his studies with half that pleasure and success which he might in either the animal or vegetable kingdoms.

To his lasting praise, and the singular improvement of true physiology, the anatomist has examined the living body, and has there observed, that all motion proceeds immediately from the muscular fibre; that the muscular fibre again derives its power from the nerve, which terminates in the brain; that fibre and nerve, and the whole system, are nourished by the blood which comes from the heart; and that the waste of blood is supplied by the lacteals, which absorb nutritious matter from the food as it passes along the intestinal canal.

He has also observed, that the blood, which is in continual motion, has a circular course; that other vessels along with the lacteals are employed to absorb; and by means of injection has shown the route of the different fluids as clearly in the dead as they could have been seen in the living subject.

When his eyes have failed in tracing objects that were too minute for unaided sight, he has called in the help of the microscope, and discovered the red globules of the blood, animalculæ in the semen, and the anastomoses of the arteries and veins; and when the microscope could lead him no further, he has had recourse to chemical

PHYSIOLOGY.

analysis, and made discoveries equally important in demonstrating the bodies which compose the several fluids and the solids.

Besides these services which the anatomist has rendered to physiology, the science is likewise greatly indebted to him for those various and ingenious methods which he has taken to diffuse his knowledge. Whatever has occurred remarkable or rare he has studied to preserve, either dried, or in fluids that resist putrefaction. By corroding the parts which he has injected, in a certain acid, he has given an idea of the vascular system, which is at once instructive and elegant. Where it has been necessary to destroy the parts when incapable of preservation, or where the preservation would have been expensive, he has not neglected to represent them in models of wax, or to perpetuate them in accurate casts of lead or of stucco: and, lastly, that the valuable fruits of his labours might not be confined in his room of preparations or to his pupils, he has described most of them in drawings, has multiplied his drawings by correct engravings; he has even published his numerous engravings, and, to render them intelligible, has illustrated each with copious explanations.

Formerly, indeed, and in reality till within the last half century, anatomy was principally studied with a view to the art of surgery: but it has of late taken a much more extensive and liberal scope; and the bodies of brutes of all kinds have been dissected, and the vast diversity of their structures investigated, with the express intention of enlarging our knowledge upon the subject of physiology. In addition to which the bowels of the earth have been cautiously scrutinized for petrified remains of species, kinds, and orders that have been extinct for ages; and thus geology has been called in to contribute with her powerful aid (for powerful it has of late been discovered) towards the common object.

Every science can only be studied accurately under distinct chapters or divisions; and it has always been an object, and always ought to be so, to give such divisions a methodic arrangement. This plan has, therefore, been pursued in a variety of instances, in regard to physiology; but it has seldom been pursued with great success. It has been thought by many speculatists advisable to attempt one common system for the sister studies of anatomy and physiology; and possibly some few advantages might hereby be attained on the score of simplicity. Yet, for a variety of reasons, such an union is not possible. Anatomy examines for the most part the dead subject; physiology altogether the living: the chief object of attention to anatomy is the structure of the organ; the chief object of attention to physiology is the powers of the function: the former confines its views to what is visible and palpable; the latter extends them from what is visible and palpable to what is consequent and probable.

Amongst the best physiological systemists of modern times, we may mention the names of Haller, Daubenton, Vic d'Azyr, and Richerand; and it may be advantageous to take a brief survey of their respective views upon this subject.

There is great simplicity, and an elegant climax in the scheme of the first of these writers; but it is a scheme of very limited extent: it is chiefly drawn from the organs and functions of the human subject, and chiefly, therefore, limited to the subject from which it is drawn. Haller commences his celebrated *Outlines* with the simple fibre, and

the cellular texture, of which he is anxious to compose as many of the solids as he can. He then proceeds to more of the organs, describing with great erudition and care their different uses and structure in man. These organs, however, which he describes, and those analogous with respect to their structure, are confined to a part of the animal creation. As different classes of the animal kingdom have with similar functions varieties of organs, and as one function is consequently performed in different ways, it is evident that organs ought not to form the general divisions in any physiological system of arrangement, because we should then have a new arrangement for every new species of organs. Of this truth Haller and others have not been ignorant. They have also divided their subject into functions; but still they are functions in the manner performed by the human body. This body has engrossed so much of physiology, that we often see the functions explained with scarcely any allusion to their organs; as these are supposed to be always the same, and already known from the usual dissections.

Haller's physiology is professedly that of the human body. His conduct here was seemingly the effect of general custom: it did not arise from any contempt of comparative anatomy. There have been few who esteemed it so highly, who have studied it more, or applied it so skillfully. He declares there are many parts of our bodies whose functions can never be fully explained, unless we examine their structure in quadrupeds, in birds, in fishes, and even in insects; though he therefore had dissected of human subjects to the number of 350, yet the number which he dissected of brutes, and, what is more, dissected alive, was much greater. Numerous, however, as were his dissections, they were too confined for general physiology. That requires a range more extensive; and, to shorten the labour, different classifications of animals from any of those to be usually met with. This assertion hardly needs a proof.

There is nothing more certain, than that, were the anatomist to dissect animals as they occur in the system of Linnéus, or any other naturalist, his toil would be immense, and the knowledge which he thence would acquire of functions would scarcely be found to bear to it even the smallest proportion. By this observation we mean not to object to those ingenious classifications which Linnéus and others have employed to facilitate the study of zoology. All their classifications may be useful; and many display that extent and clearness of comprehension, that distinguishing acuteness, and that laudable ardour for the interest of science, which ought to render their authors immortal, and entitle them to the gratitude of future ages. Yet these systems, like those we have already observed with respect to anatomy, are formed with a view different from that which principally ought to direct the physiologist. They are meant to contain a full enumeration of the objects of zoology so far as known; to exhibit them arranged in different classes and subordinate divisions, according to such obvious and distinct marks as may strike at a glance, or appear on a cursory examination. To him who is entering on the study of zoology, they show at once the extent of his subject; they elevate his mind by the grandeur of the prospect; and when better employed than in pleasing the fancy, or in rousing the rapturous feelings of a poet, they draw his attention to those significant and marked signs in which the language of nature is written. They assist his

PHYSIOLOGY.

judgment in the art of arrangement, and give to his memory a power of recollection which it had not before. To the natural historian they perform a service equally important, if not essential, to his undertaking: to him they supply the place of chronology; and instruct his readers by the chain of connection which they give to his thoughts, and by that perspicuity which they invariably bestow on his language.

These arrangements, however, with all their advantages, are not the arrangements which the physiologist must wish the anatomist to observe in his dissections. They are certainly useful in studying the manners, dispositions, and habits of different animals, and all that part of the outward economy which indicates something of their wisdom and design. But they little illustrate that internal structure on which this outward economy is founded, or tend to explain the more secret functions, which, not depending on the will of the creature, only display the power and omniscience of him who made it. This consequence is easily conceived, from considering the difference between zoology, and what has been defined physiology. Zoology is chiefly led to examine the animal kingdom as it usually presents itself to the eye, including a great variety of objects; physiology, only that single part of the animal economy which is chiefly made known by anatomy and chemistry. Zoology has been wont to divide its kingdom into so many classes or orders of animals; physiology, as we have already observed, must naturally divide

its economy into so many functions. Zoology has subdivided its classes by certain obvious and exterior marks, as the teeth and the claws; physiology must naturally subdivide its functions by the many varieties of those organs which are destined to perform them, as the different kinds of lungs and of stomachs. Zoology but cursorily mentions the functions as forming a part of the history of animals; physiology takes notice of animals only when they are of use to illustrate its functions. From this comparison it will readily appear, that things which are primary in a zoological will often be secondary in a physiological species of arrangement; and that things which are primary in a physiological will often be more than secondary objects in a zoological. This is very conspicuously the case in one of the grand divisions of Linnæus into mammalia, where the important secretory organs of the milky fluid are noticed only, like the colour of hair or the length of a tail, as a good outward mark of distinction.

We have dwelt the longer upon this subject because it applies in a considerable though not in an equal degree to the general table of Daubenton, the great associate of Buffon, and to whom the latter was chiefly indebted for his facts. This table we shall now subjoin; and the reader will see that although Daubenton had expressly declared that there was more of art than of nature, of outward show than of inward reference, in the common arrangements, it contains not the smallest allusion to the important function of digestion.

GENERAL CLASSIFICATION OF ANIMALS.

GENERAL CLASSIFICATION OF ANIMALS.							
WITH A HEAD.				THE MOST PART WITHOUT A HEAD.			
Nostrils.				Without nostrils.			
Ears.				Without ears.			
Two ventricles in the heart.		One ventricle in the heart.		The heart variously formed or unknown.			
Warm blood.		Blood nearly cold.		A whitish fluid instead of blood.			
Inspiration and expiration of the air at short intervals.		Inspiration and expiration of the air at long intervals.		Admission of air by gills.		Admission of the air by spiracula.	
Viviparous.				Oviparous.			
With teats.				Without teats.			
I. ORDER. <i>Quadrupeds.</i>	II. ORDER. <i>Cetaceous Animals.</i>	III. ORDER. <i>Birds.</i>	IV. ORDER. <i>Oviparous Quadrupeds.</i>	V. ORDER. <i>Serpents.</i>	VI. ORDER. <i>Fishes.</i>	VII. ORDER. <i>Insects.</i>	VIII. ORDER. <i>Worms.</i>
Four feet and hairy skin.	Fins and no hair.	Feathers.	Four feet and no hair.	Scales without feet or fins.	Scales with fins.	Antennæ.	Neither feet nor scales.

PHYSIOLOGY.

It is plain from this table, and from what we have mentioned concerning Haller, that it would be injustice to physiologists and naturalists to say they have never paid any attention to correct modes of arrangements. It should rather be objected that they have not paid to them all that attention which they deserve; and that no general physiological system of arrangement existed till the attempt of D'Azyr.

This excellent writer has sufficiently shown that in such an arrangement functions should form its primary divisions; that its subdivisions should be the varieties of these functions; that the whole should be both distinguished and explained by the kinds and varieties of those organs by which they are performed; and that the descriptions of these organs might partly be collected from the several works of natural historians and comparative anatomists, as the dissections of the French academy, numerous fragments of the Curieux de la Nature, the collections of Blasius and Valentini, the writings of Haller, the works of the celebrated Hunters and Monros, the publications of Hewson and Cruikshank, and others

who have been making discoveries in the system of absorbents. D'Azyr has mentioned a great many more. He particularly recommends Per-rault, Du Verney, Collins, and Daubenton, on birds and quadrupeds; Charas, Roesel, and Fontana, on reptiles; Ray and Willughby, Artedi, the Gouans, and Broussonet, on fishes; Swammerdam, Malpighi, and Reaumur, the Geoffroys, Bonnet, and Lyonnet, on insects; and, lastly, the curious researches of Willis, Ellis, and Donati; of Trembley, Baker, Baster, and Boadsch; of Forskal, Adanson, Muller, Pallas, Spallanzani, and Diquemare, concerning worms, zoophytes, and poly-pes. Where any errors are to be corrected, or where any deficiencies are to be supplied, it is needless to observe, that recourse must be had to new examinations and to new dissections; in which it may be of some use to attend to the foods of animals, to their places of abode, and their modes of life, as circumstances leading to some internal varieties of structure. To this list of authors we should now add the names of Vic d'Azyr himself, Campfer, Blumenbach, Cuvier, Home, Darwin, Richerand, and Mirbell.

CLASSIFICATION OF THE FUNCTIONS OR PROPERTIES OF LIVING BODIES.

- | | | |
|-----------------|------------------|------------------|
| 1. Digestion. | 4. Respiration. | 7. Generation. |
| 2. Nutrition. | 5. Secretion. | 8. Irritability. |
| 3. Circulation. | 6. Ossification. | 9. Sensibility. |

Every body in which one or more of these functions are observed, is to be considered as possessing organization and life.

1 Digestion.	Living bodies which have	One or more stomachs, easily distinguishable from the œsophagus and intestinal canal,	{	Man.
		A stomach distinguishable only by certain expansions from the œsophagus and intestinal canal,		Quadrupeds.
		An alimentary canal, not distinguishable into œsophagus, stomach, and intestines,	{	Cetaceous animals.
		Neither stomach nor intestines,		Birds.
			{	Crustaceous animals.
				Oviparous quadrupeds.
			{	Serpents.
				Cartilaginous fishes.
			{	Fishes properly so called.
				Insects.
			{	Worms.
				Zoophytes.
			{	Plants.

2 Nutrition.	Living bodies whose nutritious juices are absorbed	By vessels beginning from internal cavities,	{	Man.
		By vessels opening upon the external surface,		Quadrupeds.
			{	Cetaceous animals.
				Birds.
			{	Oviparous quadrupeds.
				Serpents.
			{	Cartilaginous fishes.
				Fishes properly so called.
			{	Insects.
				Crustaceous animals.
			{	Worms.
				Plants.

P H Y S I O L O G Y .

3
Circulation.

Living bodies

with blood

- Having a heart with two ventricles and two auricles,
- With one ventricle divided into several cavities and two auricles,
- With one ventricle and one auricle,

- Man.
- Quadrupeds.
- Cetaceous animals.
- Birds.
- Oviparous quadrupeds.
- Serpents.
- Cartilaginous fishes.
- Fishes properly so called.

with juices with a whitish fluid

- Whose heart is formed of one longitudinal vessel, tuberos and contractile, in which there is a whitish fluid instead of blood,
- In which no heart has been yet observed, but only vessels filled with juices of a nature different from that of blood,

- Crustaceous animals.
- Insects.
- Worms.
- In some crustaceous animals there is observed something resembling a heart.

- Zoophytes.
- Plants.

4
Respiration.

Living bodies

which respire

- By lungs free from all adhesion and spongy,
- By lungs free from all adhesion, vesicular, and muscular,
- By lungs adhering to the ribs, and provided with appendages,
- By gills of different forms,
- By stigmata or holes in different rings,
- By an opening called trachea, or by external fringes,
- By tracheæ,
- In which there have been discovered neither stigmata nor tracheæ,

- Man.
- Quadrupeds.
- Cetaceous animals.
- Oviparous quadrupeds.
- Serpents.
- Birds.
- Cartilaginous fishes.
- Fishes properly so called.
- Crustaceous animals.
- Insects.
- Earth worms.
- Aquatic worms.
- Plants.
- Polypes.

5
Secretion.

Living bodies

- There are no bodies in which secretions are not carried on.

6
Ossification.

Living bodies

whose skeleton is

- Internal and osseous,
- Internal and cartilaginous,
- External and corneous,
- External and cretaceous,
- External and ligneous,
- Which have no skeleton,

- Man.
- Quadrupeds.
- Cetaceous animals.
- Birds.
- Oviparous quadrupeds.
- Serpents.
- Fishes properly so called.
- Cartilaginous fishes.
- Perfect insects.
- Lithophytes.
- Crustaceous animals.
- Shell-fish.
- Madrepores.
- The greatest part of zoophytes.
- Plants.
- Insects in their first state.
- Worms.
- Polypes.

P H Y S I O L O G Y.

7 Generation.	Living bodies	which are	Viviparous,	Man.
			Oviparous, whether the evolution of the eggs takes place within or without the female,	Quadrupeds.
				Cetaceous animals.
8 Irritability.	Living bodies	which have	Which propagate by slips,	Birds.
				Oviparous quadrupeds.
			A body muscular or contractile,	Serpents.
				Cartilaginous fishes.
				Fishes properly so called.
				Insects.
				Crustaceous animals.
				Worms.
				Plants.
				Worms.
				Polypes.
				Plants.
9 Sensibility.	Living bodies	which have	Muscles covering the skeleton,	Greatest part of insects in the first state of their transformation.
				Worms.
			A skeleton covering the muscles,	Polypes.
				Man.
			No muscular power; no spontaneous movements,	Quadrupeds.
				Cetaceous animals.
				Birds.
				Oviparous quadrupeds.
				Serpents.
				Cartilaginous fishes.
				Fishes properly so called.
				Perfect insects.
				Crustaceous animals.
				Plants.
	Living bodies	which have	Nerves and brain easily distinguishable from the spinal marrow,	Man.
				Quadrupeds.
			Nerves and brain scarcely distinguishable from the spinal marrow.	Cetaceous animals.
				Birds.
			In which there have not yet been discovered nerves or brain, or spinal marrow.	Oviparous quadrupeds.
				Serpents.
				Cartilaginous fishes.
				Fishes properly so called.
				Insects.
				Crustaceous animals.
				Worms.
				Zoophytes.
				Plants.

The above table, which has its divisions marked by the functions, and their kinds and varieties by the kinds and varieties of those organs by which they are performed, differs considerably from a zoological table. Borrowing its several marks of distinction from internal characters, it more clearly demonstrates the difference between the mineral, vegetable, and animal, than any system that attempts to arrange by outward appearances.

No minerals, whatever be their forms or the regularity and beauty of their figures, were ever said to possess any thing like organs of nutrition; and however frequently some may recover their lost shapes, they are never supposed either to produce, or assist in producing, their own kind by generative powers. And no plants, however much may be said of animals that want a nervous system and a heart, and are fixed, without the power of loco-motion, to one place; we say, no plants, though some may represent a few of the simpler effects of sensation, and others may be free to float through the ocean, were ever said to discover

any signs of voracity, to possess any thing resembling a stomach, to distend their body by swallowing their food, to apply their food to the mouths of absorbents opening internally; and, when the nutritious juices were extracted, to eject it *in cumulo*. It has been said that zoophytes present similar phenomena. But what are zoophytes? One half of their name would imply that they are animals, and another half would insinuate that they are plants. Daubenton reasons with clearness on this subject. True, says he, the greatest part of them are branched like plants, and like plants are composed of concentric circles. Some have a soft exterior substance which is called bark, and a hard interior which is called wood. Along their branches, and at their extremities, they put forth vesicles which resemble buds; and when a part falls from the whole, it is sufficient, like a vegetable slip, to produce a zoophyte; but do these appearances prove that they are plants?

If ramifications constitute a plant, then many

P H Y S I O L O G Y.

crystallizations will be plants; the shootings of frost on our windows will be plants; the silver tree of Diana a plant; our veins will be plants, our arteries plants; and our very feet, which ramify into toes, and our hands into fingers, will have some title to be called plants. The truth is, ramification is not universal in the vegetable kingdom; and although it be general, it is no more peculiar to plants, than swimming is to fishes, or flying to birds. If concentric circles constitute a plant, some bones of animals will then be plants, and some minerals must also be plants. The wood and the bark are only two metaphorical expressions, which with equal propriety might have been used of the bone and periosteum. But once suppose the zoophyte a plant, it was natural to carry on the analogy, and certainly necessary to have it provided with wood and bark; though it must be allowed that a corneous substance is not what we commonly mean by bark, nor an evidently hard calcareous substance what we mean by wood. The small vesicles, except in appearance, have no similarity to buds or fruits; they are the residences of small polypes, to whom the whole structure has been owing, by whom the whole either is now or has been inhabited, and to whom it answers the same purpose as the shell does to testaceous animals.

After thus endeavouring to point out the boundaries between the mineral, the plant, and the animal, before we begin to treat of the functions, we must also take notice of another distinction, the want of which has occasioned much unnecessary trouble, and has given rise to not a few ridiculous disputes. This is the distinction between living bodies and some ingenious contrivances of art, which are called machines. It has not been asserted that any machine can either grow or propagate its kind; that it can assimilate the particles of matter that come in contact; that it is able to repair the injuries which it may suffer; that it can accommodate itself to circumstances; can create heat when the cold is keen, or cold when the heat becomes too violent: yet it has been supposed, from established prejudices, and from the successive evolution of parts in plants and in animals, that there is an analogy between a machine and a living body. The living body has been

called a machine; and notwithstanding the acknowledged truth of that observation so often repeated since the days of Hippocrates, that the whole is a circle, that nothing is first and nothing last in the animal economy, we are still talking as if living bodies were nought but machines; we are still reasoning as if their parts had existed in succession, had acted in succession, were combined in succession; we are still seeking for what is prior and what is posterior, for what is derived and what is original in point of structure, as if we were examining a work of art; we speak gravely of the viscera, of the thorax deriving a coat from the membranous pleura, the abdominal viscera from the peritoneum, and the branches of nerves deriving a pair from the dura and pia mater of the head; we argue with people who maintain that fasciæ are nervous expansions, and the muscles themselves but nervous productions: and although we be hardly able to conceive how the brain could be nourished without blood thrown from the heart, or the heart move without the assistance of nerves from the brain, we are still disputing about which was prior and which was posterior in point of existence; a dispute that will probably terminate as soon as that of the ancients, whether the first eggs were from birds, or the first birds were hatched out of eggs.

These dark and inscrutable mysteries of nature we presume not to explain; they point out almost the creative hand, and bring us almost into the immediate presence of that Being by whom we live, move, and exist; and before whom the truly feeling and elevated mind is less disposed to examine than adore. We are only to observe, that from this coeval formation of parts which the microscopic power of anatomy has often distinguished from their evolutions, and from this mutual dependence of organs one on another, we are left at freedom to begin at any part of the circle, and treat of the general properties and functions of living bodies.

The arrangement of Vic d'Azyr has been remodelled and certainly improved by M. Richerand, who has also thrown it into a somewhat more systematic construction under the following form.

PHYSIOLOGY.

CLASS I. FUNCTIONS CONTRIBUTING TO THE PRESERVATION OF THE INDIVIDUAL. (Individual life.)

FIRST ORDER.

By assimilating alimentary matters to his own substance.

(Assimilating, internal, or nutritive functions.)

GENUS I.—*Digestion.*
Extracts from it the nutritive parts.....

II.—*Absorption.*
Carries it into the circulating fluid.....

III.—*Circulation.*
Conveys it to all the organs.....

IV.—*Respiration.*
Combines it with the oxygen of the atmosphere.

V.—*Secretion.*
Makes it undergo various modifications.....

VI.—*Nutrition.*
Applies it to the organs for the purposes of growth and repair.....

Prehension of food.
Mastication.
Salivary secretion.
Deglutition.
Digestion.
Chylification.
Excretion of feces and urine.
Absorption of chyle.
—— lymph.
Action of vessels.
—— glands.
—— thoracic duct.
Action of the heart.
—— arteries.
—— capillary vessels.
—— veins.
Action of the parietes of the thorax.
—— lungs.
Changes in the air.
—— blood.
Animal heat.
Transudation of serum.
Mucous secretion.
Action of glands.
Differing in every part according to its peculiar composition.

SECOND ORDER.

By establishing his relations to surrounding beings..

(External, or relative functions.)

GENUS I.—*Sensations.*
Inform him of their presence.....

II.—*Motions.*
Enable him to approach to or avoid them.....

III.—*Voice and Speech.*
Give him the power of communicating with his species, without change of situation.....

Of sight.
— hearing.
— smelling.
— tasting.
— touching.
Action of the nerves.
—— brain.
Human understanding.
Perception.
Memory.
Judgment.
Volition.
Sleeping and waking.
Dreams.
Somnambulism.
Muscular organs and action.
Skeleton.
Articulations.
Standing.
Progressive motions.
Motions of the upper extremities.
The voice { articulated; or
speech:
modulated; or
singing.
Stammering.
Lisping.
Dumbness.
Ventriloquism.

FIRST ORDER.

Whether they require the co-operation of both sexes.....

SECOND ORDER.

Or belong exclusively to the female..

Conception.....

Generation.....

Gestation.....

Parturition.....

Suckling.....

General differences of sex.
Hermaphrodites.
Systems of generation.
Pregnant uterus.
History of the embryo.
—— fetus.
—— coverings of the fetus.
State of the uterus after parturition.
Lochia.
Action of the breasts.
Milk.

CLASS II. FUNCTIONS CONTRIBUTING TO THE PRESERVATION OF THE SPECIES..... (Life of the species.)

PHYSIOLOGY.

<i>Growth of the body</i>	{	Infancy—Dentition—Ossification.
		Puberty—Menstruation.

<i>Decline of the body.</i>		{
	Decrepitude.	
<i>Death.</i>		
<i>Putrefaction.</i>		

In our physiological observations upon these separate functions we shall adhere to this classification of M. Richerand, though we shall considerably deviate from the remarks which he has offered under each head, as not sufficiently interesting or popular for such a work as the present. We commence with the FIRST ORDER of his FIRST CLASS, comprising the functions that are contributory to the life of the individual, by assimilating alimentary matters to its own substance.

GENUS I.—*Digestion.*

This, in our opinion, is properly contemplated and characterised, as the first of the genera of functions under the class of those that serve to the preservation of the individual. The very acute and well informed author of the article upon this subject in the *Encyclopædia Britannica* has regarded respiration as the first of these functions in a systematic arrangement. His arrangement, however, is founded upon fetal life, and ours upon adult life. In the former view it is unquestionably correct: but then it is erroneous to take it in this view; for if the author had not himself immediately afterwards departed from it, he would have had no opportunity of describing digestion in any part of his plan; and as little of adverting to respiration, voice, or the various processes of generation, manhood, old age, and decrepitude; none of these belonging to the stage of life from whence his arrangement is deduced. The proper period from which the classification should be drawn is unquestionably that of maturity, or of life in its most perfect state; looking equally forward and backward, and in the actual possession of the greatest number of functions and of those functions in their fullest expansion and consummation.

Digestion is the process by which the liquid and solid part of the food undergoes its first preparation in the system, and as the effects of the digesting and assimilating powers are more surprising than any chemical process of art, it may not be unpleasant to take a particular view of them. It has long been observed, that those animals which are not carnivorous feed upon plants; and, since the days of Van Helmont and Boyle, it has been suspected that plants live upon water and air. This suspicion has now been confirmed by numerous experiments. Plants have been raised from distilled water without earth, and, instead of requiring a vegetable mould, have spread

their roots in moss, in paper, in cotton, in pieces of cloth, in pounded glass, and powder of quartz. From these facts, the ingenious Chaptal has been led to suppose that soils act but as so many sponges, affording water in different proportions, and in different ways; and that all that the plant wants from the soil is a firm support, a permission to extend its roots where it chooses, and that proportioned supply of humidity which will secure it against the alternatives of being inundated or dried up. To answer, however, these several conditions, he allows it to be necessary in many cases to make a proper mixture of the primitive earths, as no one in particular possesses them. Siliceous and calcareous earths (he says) may be considered as hot and drying, the argillaceous as moist and cold, and the magnesian as possessing intermediate properties. Each, in particular, has its faults, which render it unfit for culture. Clay absorbs water, but does not communicate it; calcareous earth receives and gives it too quickly: but the properties of these earths are so happily opposed that they correct each other by mixture. Accordingly we find, that by adding lime to an argillaceous earth, this last is divided, and the drying property of the lime mitigated, at the same time that the stiffness of the clay is diminished. On these accounts it is that a single earth cannot constitute manure, and that the character of the earth intended to be ameliorated ought to be studied before the choice of any addition is decided on. The best proportions of a fertile earth for corn are three eighths of clay, two eighths of sand, and three eighths of the fragments of hard stone.

“The advantages of labour consist in dividing the earth, aerating it, destroying useless or noxious plants, and converting them into manure by facilitating their decomposition.”

So far is vegetable mould from communicating any thing new to plants, that it rather owes its formation to them; and if sea salt should at times be requisite to marine vegetations, it is to be remembered that salts, sulphur, and lime, are all products of organized bodies; that iron itself has been discovered in plants and animals; and that even diamonds, quartz, crystals, spars, gypsum, &c. are found only in those earths that are partly composed of an impoverished vegetable residue, which provident nature seems to have reserved for the reproduction or reparation of the earthy and metallic substances of the globe; while the

PHYSIOLOGY.

vegetable mould on these organic parts that remain is made to serve as nourishment for the growth of succeeding plants.

If those earths in which plants are reared, and which contain no vegetable mould, should ever be sensibly diminished in weight, a circumstance, we believe, which seldom takes place if proper precaution be used to prevent it; yet, if it should happen, it should not in that case be forgotten that gasses are the general cements in nature; that they mix intimately with the hardest bodies; and that this sensible diminution of weight may be owing entirely to some dissolution of the solid parts, and the consequent extrication of the gaseous fluids.

"Before we had acquired a knowledge of the constituent principles of water," resumes Chaptal, "it was impossible to explain or even to conceive the growth of plants by this single aliment. In fact, if the water were an element, or indecomposable principle, it would afford nothing but water in entering into the nutrition of the plant, and the vegetable would of course exhibit that fluid only; but when we consider water as formed by the combination of the oxygenous and hydrogenous gasses, it is easily understood that this compound is reduced to its principles, and that the hydrogenous gas becomes a principle of the vegetable, while the oxygen is thrown off by the vital forces. Accordingly we see the vegetable almost entirely formed of hydrogen. Oils, resins, and mucilage, consist of scarcely any thing but this substance; and we perceive the oxygenous gas escape by the pores where the action of light causes its disengagement."

But though water constitute the aliment of plants, we must not suppose that it is the aliment of these alone: the leech and the tadpole are nourished by water, and many animals have no other food. "Rondelet cites a great number of examples of marine animals which cannot subsist but by means of water by the very constitution of their organs. He affirms, that he kept during three years a fish in a vessel constantly maintained full of very pure water. It grew to such a size, that at the end of that time the vessel could no longer contain it. He relates this as a very common fact. We likewise observe, that the red fishes which are kept in glass vessels are nourished, and grow, without any other assistance than that of water properly renewed."

The ingenious Borelli, who knew that plants and several animals subsisted wholly by water and air, was likewise of opinion that some animals lived upon sand. He could discover nothing but sand in the stomachs of many testaceous animals that live in the water, and particularly in the stomachs of the smaller kinds that live buried in the sand of the sea. He could not conceive what else could be the food of those small fishes or worms which penetrate the substance of the hardest rocks, and form excavations that always bear a proportion to their bulk. He had regularly found that the stomachs of swans which he had examined were full of sand; and, recollecting the pebbles in the gizzards of fowls, he was led to infer that these substances were somehow dissolved in a gastric juice, and served to nourish the harder parts, as the shells, the feathers, and the bones. These sentiments, on a slight view, might not be unnatural. From observing children of depraved appetites swallowing sand, ashes, and cinders; from having sometimes met with sand in the stomachs of wild ducks; from the usual fæces of the

earth-worm; and from the dissection of several toads dug up in a garden, in whose stomachs we could see nothing but a quantity of earth, with pieces of coal, stone, and of slate, that had accidentally happened to be mixed with it, we long entertained a similar opinion with this celebrated author: but on recollecting that many substances which enter the stomach are not nutritious; considering the balls of hair and of feathers which the carnivorous animals return, and that quantity of faecal matter which is discharged by the intestines; having frequently experienced that a sense of fulness removes hunger, and observed persons as it were by instinct pressing on the empty stomach with their hand—we began to suspect that the swallowing of sand, and a number of other indigestible substances, might not be to nourish but to prevent some cravings of the stomach, and that these cravings were in part occasioned by a deficiency of the usual pressure which it receives from the neighbouring parts. In this opinion we were more confirmed, by hearing it was customary among some of the tribes of the north of Asia to repel or mitigate the attacks of hunger by placing a board over the region which is called epigastric, and compressing it gradually by means of cords as the stomach collapses; and by learning afterwards, on a farther enquiry, that a similar practice, and from similar motives, was likewise common with some individuals in this country; who, to alleviate the sensation of hunger, straiten the epigastric region with their handkerchief. This practice, however, being often impossible with the brute kind, instead of bringing the neighbouring parts to press on the stomach, they are obliged to distend the stomach, and to bring it to press on the neighbouring parts. Of the two ways of producing this pressure, the last is certainly the most natural. Senebier has supposed that distension of the stomach is the cause of the secretion of the gastric liquor; but how well or ill his opinion may be founded, daily experience permits not a doubt, that, in order to satisfy the calls of hunger, the stomach requires not only to be nourished, but to be filled, or at least to have something like a sense of fulness; and this may probably be one reason for those balls which are found in the stomachs of the chamois, which likewise swallows sand, and in the stomachs of the cow, the sheep, the horse, "when they do pass away the winter in snowy mountains, where they can find no grass."

From this general view of the food, the natural transition is to those organs by which it is prepared. As all plants are fed on nothing grosser than liquids, we see the reason why they are all nourished by absorbents, and why, instead of one common alimentary canal, they are furnished with a number of capillary vessels, which by their action assist the living power in moving the fluids along the trunk, the branches, and the leaves. These fluids are observed to move between the different ligneous circles, and the more copiously as the wood is younger or the nearer the circles are to the bark. In the circles themselves, it has been remarked that the sap-vessels, from being empty during a great part of the growing season, have been called air-vessels; that they are formed of spiral fibres, adapted to some peristaltic motion: and it is plain, that by this structure they are well fitted to propel their contents, whether water or air, upwards or downwards, backwards or forwards, according to the different positions of the plant.

PHYSIOLOGY.

Besides the particular action of the vessels, a general concussion is received from the movement of the waters or winds, which serves as an exercise; a general dilatation is occasioned by both moisture and heat; and a general contraction by dryness and cold, which produce a motion something similar to that of the thorax.

In the springing season the sap ascends through the empty vessels before the leaves begin to appear. When the vessels are filled through their whole extent, the buds swell, the leaves spread, and the flowers blow; the evaporation from the surface is increased; the sap is diminished by the absorption; the succiferous vessels now cease to bleed; and the roots being unable to supply the waste, the rains and the dews enter by the trunk, the branches, the leaves, and the petals of the flowers. When the evacuations are immoderately increased by excessive heat, or preternaturally obstructed by the plucking of the leaves, by too much humidity, or other causes which prevent perspiration, the plant soon either sickens or dies. The chyle, which is formed in the sap vessels, has generally something of a saccharine taste.

Considering the forms of animal food, we may naturally expect in the animal kingdom a greater variety of those organs employed in digestion. Most animals have indeed, like the vegetable, both inhaling and exhaling vessels, by which some of their fluids are absorbed, and evacuations regularly carried on. Except, however, in those animals which subsist by liquids, these vessels are of little importance in receiving food or ejecting what is fecal from the system. In these animals the absorbents terminate in a hollow viscus, which is called the alimentary canal, where the fluids undergo a preparatory change, and are partly reabsorbed for assimilation. In all others the food enters by a proboscis, or by an aperture which is called the mouth: this mouth is properly the entrance of the alimentary duct. It is very generally furnished with a tongue, which is usually assisting in deglutition; and if the food be of that nature to require cutting, tearing, or grinding, it is likewise furnished with the proper instruments for these operations. When the food is testaceous or some hard vegetable substance, and these instruments not in the mouth, something similar may generally be expected in a more remote part of the canal. The crab and the lobster have accordingly grinding teeth in their stomach, and granivorous fowls have a powerful gizzard lined with a thick corneous substance. It possesses the compressing force of the jaws; and small pebbles which the animals swallow, serve it for teeth.

Besides mere trituration or grinding, the solid food will often require to be mixed with some additional liquid. In those carnivorous animals which chew, this liquid, during the time of mastication, flows into the mouth from certain glands placed in the neighbourhood. In some species of the ape kind a previous dilution takes place in two pouches situated on the sides of the lower jaw. In granivorous birds this dilution is very usually performed in a sac, which is a dilatation of the canal; and the food being macerated there by the glands or exhaling vessels, gradually passes down, as is needed, to be triturated and further prepared in the stomach. In the ruminating kind the dilution is performed in a similar manner: but these having no muscular stomach fitted for grinding, instead of descending the food is brought up again into the mouth, and is then after the proper mas-

tication sent to the stomach. If the food require no mastication, it is sent directly that way at first: a circumstance which shows a curious discernment with respect to foods, and proves that their alimentary canal is subject to the action of voluntary muscles as far as the stomach. Some of those birds which have a diluting sac or ingluvies seem likewise to ruminate. This in the parrot was observed by the gentlemen of the French academy. It has since been observed in rooks, macaws, cockatoos, and others: and Mr. Hunter, to whom physiology is so much indebted, discovered, that the male and the female pigeon secrete in their ingluvies a certain liquor for feeding their young; and that most kinds of what have been thought ruminating birds do very often in expressing their fondness regurgitate their food. Yet both this and another species of regurgitation, which is very common with those animals that swallow indigestible substances with their food, should be carefully distinguished from rumination.

To the ruminating kinds the diluting sac is by no means peculiar. The porpoise has one, though it does not ruminate; and many of those animals which have none, as the rat, the hog, and the horse, have a part of the stomach covered with a cuticle, and which must therefore principally serve as a reservoir. The gullets of several fishes and serpents are sacs of this kind. It frequently happens that a part of their prey is projecting from the mouth, while another part fills up the gullet and gradually descends, to be reduced in the solvent below. So very dilatable are the stomachs and gullets of some animals, that serpents have been often seen to swallow whole animals which, prior to the gorging, were larger than themselves; and many polypes, and even some of the louse kind, will, by swallowing food, more than double their own bulk.

Applying stomach as a general word to the different ventricles of the canal, we may here observe, that every species of animals which ruminate have two stomachs, or at least two divisions in one; that some have three, as the gazelle; and some four, as the cow, the dromedary, and the sheep; but it must not be supposed that the number of stomachs is any proof of a ruminating power. It was said already that the porpoise has two; the porcupine has three divisions in one; and the singular cassowary, although it be found to have four stomachs, does not ruminate: nor, although granivorous, is any one of the four a gizzard.

Somewhat different from these expansions which we have been mentioning as existing in the first part of the alimentary canal, is a sort of pouch which hangs from the neck and the lower mandible of several birds, and which, like the two pouches of apes, may be used either to macerate the food or to carry provisions from a distance to their young. The pelican, a native of warm countries, employs this pouch sometimes to carry a quantity of water; and another native of the same countries, we mean the dromedary, was observed to have at the top of the second of the four ventricles a number of square holes, which being the orifices of as many cavities between the membranes which compose the ventricle, reminded the gentlemen of the French academy of those large reservoirs of water which Pliny mentions to be in camels; and for which, according to his story, their guides have opened them sometimes in cases of extreme thirst.

We come now to one of the principal agents in

PHYSIOLOGY.

digestion. Independent of the fluids which mingle with the food in the mouth, the gullet, or macerating sacs, there is one denominated the gastric juice, and which, either by itself or along with others from the aliments or system, acts in some measure as a solvent. It is secreted from large glands at the entrance of the gizzard, from vessels or glands in the coats of the stomach, and perhaps most plentifully near the pylorus: it powerfully resists the putrefactive fermentation; it coagulates milk and the white of an egg; it dissolves food even when inclosed in metallic tubes; and when life ceases, it acts frequently on the very stomach from which it was secreted. Its taste, its colour, and its solvent powers, are different in different classes of animals. It seems to be modified according to the age, the health, the habit, and the different aliments on which they live. The sick and the child are incapable of digesting the food that is proper for a healthy man. The hawk kind, after loathing bread and throwing it up without any change, can be gradually brought to take it for food; and Gassendi has mentioned a certain lamb, which, being fed on bread, cheese, and on flesh, refused afterwards to taste grass. But what is most surprising in the gastric juice is, that it spares all living bodies, as those worms which exist in the stomach, and the stomach itself while it is alive; and it differs otherwise from a chemical solvent, in that it has an assimilating power, and reduces all substances, whether animal or vegetable, on which it acts, to a certain fluid of determinate properties, which is called chyle.

Besides the gastric, the food again, after passing through the stomach, is mingled with a greenish saponaceous liquor, which is called bile, and which flows either immediately from the liver or from a vesicle into which it had regurgitated as into a blind gut: at the same time nearly it is mingled with another resembling the saliva from the pancreas or sweet-bread; a gland or glands whose place is supplied in a great many fishes by a number of vermicular appendages to the stomach.

In short, from one extremity of the alimentary canal to the other, fluids are perpetually flowing into its cavity from glands, vessels, or organic pores; and the membranes constantly secreting a mucus to protect themselves from the acrimony of their contents. This acrimony must often be considerable near to that end of the canal where the fæces are discharged; for, as the first part of the canal has generally one or more dilatations which are called stomachs, and secretes at least one fluid which is strongly antiseptic, so the last part has generally appendages which are called cæca, where the food always remains for some time, and where, from the quantity of animal matter that happens to be mixed with it, it becomes putrescent. The office of the cæca is sometimes supplied by the largeness and convolutions of the colon; to which gut the ileum cannot, when it enters laterally, so easily communicate its peristaltic motion. As the stomachs were the receptacles of the food when it entered, the cæca are receptacles of the fæcal matter before it be discharged. They are of various forms and capacities; they are often larger than the stomach itself; are often composed of proportionally thin and transparent membranes; and from their contents have often a colour somewhat resembling that of the gall bladder. Their number is different in different animals. Some have but one. The birds which have them have generally two; the bustard has three; and

Swammerdam has dissected insects which had four. As some stomachs have a number of folds which hang pendulous within their cavity, and increase their surface, so have often the cæca as well as some portions of the canal. The cæcum of both the rabbit and the hare is curiously formed. It is large and beautiful: it is rolled up like a cornu ammonis; it has the like outward appearance; and a fold running spirally is observed within. The animals which live on vegetable food have usually the greatest length of the canal, and the greatest number of stomachs and of cæca: yet the cassowary, which has no gizzard, has no cæcum; and the polype, which is said to be all stomach, is, properly speaking, rather all cæcum.

To see more fully the process of digestion, we must not overlook that general and organic action which takes place through the whole alimentary canal. The power of mastication exerted in the mouth is obvious to all. But the force of some stomachs has till very lately been known to few; we allude here to that of the muscular or gizzard kind: for Abbé Spallanzani has divided stomachs into three sorts; the muscular, the membranous, and intermediate. The immortal Borelli, who was probably the first that tried the force of the muscular stomachs by throwing into them nuts of filberds, hollow spheres of glass, hollow cubes of lead, small pyramids of wood, and several other very hard substances, supposed that the power exerted by the stomach of the Indian cock was equal to 1350 pounds weight. The force of an intermediate stomach cannot be so great, and that of a membranous one must be still less. Each seems to have more of the solvent as it has less of the muscular power. The most membranous are assisted by the action of the neighbouring parts, and expel their contents as readily as the strongest. The muscular sort is either wholly or principally confined to certain kinds of birds and of fishes, as nature has meant that the grain or the shells which they use as food should be first triturated before it be subjected to the gastric juice. This comminution takes place in their stomach, because it is plain that, had bones or muscles, fully equal to all these effects, being placed in the head, the form of the animal must have been altered, or that equilibrium which it preserves in those fluid elements through which it moves been completely overturned.

As to the movements of the alimentary canal, the direction of hairs found in the stomachs, and the balls of hair which are thrown up, would appear to indicate a circular motion. The intestinal part has a motion similar to that of a worm, and is called the vermicular or peristaltic. Here every portion retains its own motion, although it be separated from the rest by ligatures. The stomach of the polype, the gullets of the ruminating kinds, and the cæca, have this motion in different directions at different times; and that observed in the alimentary canal of a louse is, when viewed through a microscope in the time of action, amazingly rapid; the stimulating causes employed are the food, the different liquors with which it is mixed, the air, the nerves where they exist, and a portion of heat. Some degree of heat is necessary to every process of digestion both in the animal and vegetable kingdom: what that degree is depends on the nature of the living body; and is various according to its age, its health, its employments, and habits. The ingenious Hunter has mentioned the digestive and generative heats; and those gardeners who are versant in the ope-

PHYSIOLOGY.

rations of hot-houses, have on their thermometers the swelling, flowering, and the ripening beats, with a great many others, for the several plants which they mean to raise.

Among the other causes of digestion some authors have ranked fermentation: and it must be allowed, that something similar to the putrefactive fermentation takes place in the cœca and the lower extremity of the intestine, and that the vinous and acetous fermentations but too frequently occur in our stomach when that viscus is morbidly affected.

Much of the history of living bodies relates to the different degrees of heat, the varieties of soil, and the kinds of food concerned in digestion. The plants grow where the soil and the heat are congenial to their nature; and those which admit of the greatest variety with respect to soil, and the largest range on the scale of heat, are the farthest dispersed over the globe. As every soil has usually some regular supply of moisture, the plants that can live upon that supply extend their roots under the surface where their liquid food is the least exposed to evaporation, and meeting there with the constant nourishment which they require, they remain in that situation for life. If their trunks be so feeble as to need a support, they creep on the ground, they climb the face of a neighbouring rock, or cling to the body of some of the statelier children of the forest. Their range for food is extremely limited: it is chiefly confined to the small space which happens to be occupied by their roots and branches; yet if any uncommon exertion be necessary, the branches will bend, and the leaves turn to drink of the water that is passing by. If the roots be laid bare, they will again plunge into the earth; if a stone or a ditch be thrown in the way, they will move round or will dip downwards, and spread into the soil on the other side: if there they arrive at one that is unfriendly, they will not enter; but if a favourite earth should be near, though not in their direction, they will twist about, advance as they grow, and at last meet it. In all these cases the prop, the water, and soil, must be necessary; they must also be within a very small distance, otherwise the plants cannot perceive them, or will fail in their languid attempts to approach them.

It may be considered as a general fact, that wherever food is liberally supplied for a whole lifetime in one place, the creatures which use it have seldom much locomotive power, or much inclination to exercise it in a long continued and progressive line. The curious insect is therefore observed to deposit its offspring in those places where the prospect of genial warmth and of plenty seems to preclude the future necessity of wandering or research; and when this offspring is about to pass into a new state, and the organs foretell that a change or perhaps a variety of food will soon be required, the appearance either of wings or of legs does likewise foreshow that the power of locomotion is to be increased. Even nobler animals in their foetal state, where they live upon one species of food, and where that is afforded in regular plenty, do spread out their roots, adhere to their soil, and become as stationary as the plant itself; and even when that supply is withdrawn, and they are expelled; yet if the state into which they immerge be helpless and feeble; if their organs of digestion have a weak solvent or masticating power, particularly adapted to some easily assimilated food; and if that food be presented either by their parent or nature with-

out their exertion, their power of locomotion is not great, nor is it exercised in wandering afar. It is when the organs of digestion are strong, and the appetite inclines to variety of aliment, that they are disposed and feel themselves able to wander in search of it; and that then they may be ready to move at intervals from place to place, when the enemy comes or the spirit prompts them, nature has directed them to solid food, and has given them a large alimentary canal with stomachs, with convolutions, and cœca, where they may lay up provisions for a journey; but, afraid to entrust them with too much freedom, lest in their excursions they might wander from the places where subsistence is found, there are two appetites, hunger and thirst, which never fail in a state of health to remind them of their duty.

This variety of food, and the manner in which it is affected by climate, are the cause of the many and singular migrations from spot to spot, from country to country, and from sea to sea: they are the cause of a state of torpor in the hedge-hog and the bear, and they partly explain the provident foresight of the ant and of the bee. Animals of great locomotive power, in order to provide for themselves and their offspring, remove to a distant country or climate when they see the signs of approaching famine. Those of less locomotive power, and who are incapable of migrating far, as if warned by heaven, lay up a store for the scarcity to come; or, should their food be of that kind as not to be easily preserved for a season, they receive no secret warning to hoard it at the time when it fails, their system becomes susceptible of torpor, and they are enabled to sleep through the storm of trouble and of want. The source of this want is in most instances to be traced to the nature of the plant and insect. The plant which has little heat of its own depends on the sun, or some other agent, for one of the great causes of digestion. When this agent refuses the necessary heat, the plant must decline; its leaves, its juices, and its fruits must fail. The insect tribe, which had no other food, or which like the plant could not maintain their vivifying warmth, must likewise submit to the same fate. The various animals which live on either the one or the other, according to their several dispositions and characters, retire to their stores, to their dens of torpor, or migrate to a country to which they are led by unseen guides to share in its abundance. Of these last the rail and the swallow are the only two which are sometimes arrested, and which, with the bear, the hedge-hog, and the toad, are obliged to remain in the dwellings of torpor till the genial season of warmth and of plenty.

GENUS II.—*Absorption.*

When the food has undergone the first preparation, which is called digestion, and the chyle is formed in the alimentary canal or sap-vessels, it is thence taken up by means of absorption for the use of the system. From the vessels it passes into the whole cellular tissue, composed of vesicles, and closely interwoven with all the vascular part of the plant. From the vesicles or utricles of the cellular tissue it enters the vasa propria and glands, which contain and prepare the fluids and secretions peculiar to the species.

In the animal economy it was always supposed that the chyle was absorbed by the ramifications of the red veins spreading on the gut, till the year 1622, when Asellius an Italian discovered the lacteals running on the mesentery of a living dog,

and printed his account of them in 1627. As he had not traced their course very far, he naturally thought that they went to the liver, which was then imagined to be the organ of sanguification. This opinion, with respect to the place where they entered the veins, continued to be general till 1651, when Pecquet in France published his account of the thoracic duct. With great candour this author acknowledged, that he had been led to make the discovery by observing a whitish fluid mixed with the blood in the right auricle of the heart of a dog, which kind of animal it had been customary to dissect alive since the time of Asellius. "This practice of opening living animals furnished likewise occasions (says Dr. Hunter) of discovering the lymphatics. This good fortune fell to the lot of Rudbec first, a young Swedish anatomist, and then to Thomas Bartholine, a Danish anatomist, who was the first who appeared in print upon the lymphatics. His book came out in 1653, that is, two years after that of Pecquet; and then it was evident that they had been seen before by Dr. Highmore and others, who had mistaken them for lacteals; but (adds Dr. Hunter) none of the anatomists of those times could make out the origin of the lymphatics, and none of the physiologists could give a satisfactory account of their use." He had not known that Glisson, who wrote in 1654, has ascribed to these vessels the office of carrying the lubricating lymph from the several cavities back into the blood; and that Frederick Hoffman has expressed the doctrine of their being absorbents very explicitly.

It was on the 19th of June 1664, that Swammerdam discovered the valves of these vessels; and Ruysch, who had seen them, perhaps very nearly about that time, first gave an account of them in a small treatise which he published at the Hague in 1665.

The best mode of demonstrating the lymphatics we probably owe to the celebrated Nuck, who, as a specimen of that complete System of Lymphography which he meant to publish, printed in 1691 his *Adenography, or Description of the Glands*. In this treatise he not only tells us how he brought them into view, but in his plates represents many of them as filled with his new mercurial injections; a happy invention, which perhaps was suggested by remarking the extreme subtilty of mercury when employed in the cure of venereal infection.

A method by which he inflated these vessels led him to suppose that they took their origin from veins or arteries, either immediately or through the intervention of some follicles. The celebrity of his name procured credit to this mistake; and notwithstanding the sounder opinion of Glisson, of Hoffman, and some others, the old notion that the veins performed the office of absorbents came so far down as the great names of Haller and of Meckel. The arguments, however, by which it was supported are shown now, and particularly by those of the Hunterian school, to have been injections that were not skilful, observations that were not accurate, and conclusions that were not logical; while the boasted assertion that birds and fishes were without lacteals and without lymphatics, has been disproved by the fortunate discoveries of Mr. Hewson and Dr. Monro. Excepting, therefore, in the penis and placenta, and in those animals whose veins may be injected from the gravid uterus, the lymphatics seem to perform the whole business of absorption. They contain a fluid that is coagulable like the lymph of the

blood, and are called valvular to distinguish them from the arteries that do not admit the red globules. They derive their origin from the cellular membrane, from the different cavities, and from the surface. Some authors say that they have seen them in the brain, and these Mascagni has ventured even to describe in prints. That some indeed may exist in the brain, has not been denied: but to believe that they have been found, and to trust assertions which are not countenanced by the observations of skilful anatomists, requires a faith which for our part we do not pretend to. Both they and the lacteals derive their name from the colour of the fluids which they contain. They both empty themselves into the veins; but most of the lymphatics in the human subject, and all the lacteals, first unite in the thoracic duct, which near the heart leads into the course of the circulation.

GENUS III.—Circulation.

After part of the food is converted into chyle, and this chyle absorbed by the lacteals, and brought into the course of the circulation, it remains to be distributed to all the different parts of the system. On this account Hippocrates speaks of the usual and constant motion of the blood, of the veins and arteries as the fountains of human nature, as the rivers that water the whole body, and which if they be dried up man dies. He says that the blood-vessels are for this reason every where dispersed through the whole body; that they give spirits, moisture, and motion; that they all spring from one; and that this one has no beginning and no end, for where there is a circle there is no beginning. In such language was the prince of physicians accustomed to express his vague ideas of a circulation; for, so far was he from having acquired accurate conceptions on this subject, that, when he saw the motions of the heart, he believed that the auricles were two bellowses to draw in air, and to ventilate the blood.

When after his time anatomy came to be more studied, the notions of the ancients respecting the blood were better defined; and, however chimerical they may seem to us, they were partly derived from dissection and experiment. On opening dead bodies, they found, that the arteries were almost empty, and that very nearly the whole of the blood was collected in the veins, and in the right auricle and ventricle of the heart. They therefore concluded that the right ventricle was a sort of laboratory; that it attracted the blood from the cavæ; by some operation rendered it fit for the purpose of nutrition, and then returned it by the way that it came. From the almost empty state of the arteries, they were led to suppose that the right ventricle prepared air, and that this air was conveyed by the arteries to temper the heat of the several parts to which the branches of the veins were distributed.

To this last notion entertained by Erasistratus, Galen added an important discovery. By certain experiments, he proved that the arteries contained blood as well as the veins. But this discovery was the occasion of some embarrassment. How was the blood to get from the right to the left ventricle? To solve the difficulty in which his new discovery had involved him, he supposed that the branches of the veins and arteries anastomosed; that when the blood was carried to the lungs by the pulmonary vein, it was partly prevented by the valves from returning; that therefore during the contraction of the thorax it passed through the

PHYSIOLOGY.

small inosculating branches to the pulmonary vein, and was thence conveyed along with the air to the left ventricle to flow in the aorta. This opinion, so agreeable to fact, unfortunately afterwards gave place to another that was the result of mere speculation. This notion was, that the left ventricle received air by the pulmonary vein, and that all its blood was derived through pores in the septum of the heart.

The passage through the septum being once suggested, and happening to be more easily conceived than one through the lungs, it was generally supposed the only one for a number of centuries; and supported likewise, as it was thought, by Galen's authority, it was deemed blasphemy in the schools of medicine to talk of another. In 1543, however, Vesalius having published his immortal work upon the structure of the human body, and given his reasons in the sixth book why he ventured to dissent from Galen, he particularly showed how it was impossible that the blood could pass through the septum of the heart. His reason roused the attention of anatomists; and every one grew eager to discover the real passage which the blood must take in going from the right to the left ventricle. The discovery of this fell first to the lot of Michael Servetus, a Spanish physician, who published his opinion, and revived the old doctrine of Galen, in 1553. But his opinion did not spread at the time; the book in which it made its appearance contained heresy, and was therefore destroyed by public authority. Fortunately, however, the same discovery was again made by Realduus Columbus, professor of anatomy first at Padua, and afterwards at Rome, who printed his account of it in 1559. Many others who were engaged in the same research were equally successful, and Andreas Cæsalpinus, even singularly lucky. It appears by his *Peripatetic Questions* printed at Venice in 1571, and reprinted there with his *Medical Questions* in 1593, that he knew not only the lesser circulation, but had observed that there were times when the blood flowed from the branches of the veins towards their trunks, and that veins swelled between their ligature and the extremities, and not between the ligature and the heart. From these observations, he necessarily inferred that the veins and arteries anastomosed; and having also contemplated the nature of all the valves which were then known, and had been known since the days of Galen, he ventured to assert that the blood could not return by the arteries to the left ventricle. One should imagine that from such conclusions he must have discovered the true circulation; but he did not. Being a zealous Peripatetic, he thought himself bound to maintain with Aristotle that the blood flowed, like the tides of Euripus, backwards and forwards in the same channel; and therefore supposed that it flowed from the arteries into the veins in the time of sleep, and from the veins back into the arteries in the time of waking. The greater circulation, so far as we can learn, was not even dreamed of by this writer. A farther step was yet to be made towards its discovery; and this was reserved for another professor of the Paduan school.

In 1574, Hieronymus Fabricius ab Aquapendente, while he was seeking for a cause to explain the varicose swellings of some veins which had arisen from friction and ligature, he to his great joy and astonishment discovered their valves in one of his dissections: and here again the true theory of circulation seemed almost unavoidable. Yet whoever reads the small treatise *De Venerum*

Ostiolis, first printed by Fabricius in 1603, will soon perceive that he was as far from entertaining a just notion of the circulation as his predecessors. Notwithstanding all that he saw, he still was of opinion that the blood flowed from the heart to the extremities even in the veins. He thought that the valves were intended by nature only to check and moderate its force. He calls them an instance of admirable wisdom, and mistakes his own awkward conjecture for one of the designs of infinite intelligence. In another respect, it must be confessed that he bore no inconsiderable share in promoting the discovery of the circulation. By writing on the valves, the formation of the fœtus, and the chick in ovo, he directed the attention of his pupil Harvey to those subjects where it was likely that the motion of the blood would frequently occur.

Harvey was born at Folkstone in Kent, in 1578, completed his studies at the university of Cambridge, went to Padua, and was there admitted to the degree of doctor, with unusual marks of approbation, in 1602. He examined the valves with more accuracy than his master Fabricius; and explained their use in a treatise which he published some time after. It is uncertain when he first conceived his celebrated doctrine of the circulation; but about 1616 he taught it in his lectures, and printed it in 1628. He was the first author who spoke consistently of the motion of the blood, and who, unbiassed by the doctrine of the ancients, drew rational conclusions from his experiments and observations. His books present us with many indications of a great mind, acute discernment, unwearied application, original remark, bold enquiry, and a clear, forcible, and manly reasoning; and every one who considers the surprise which his doctrine occasioned among the anatomists of those days, the strong opposition that it met with from some, and those numerous and powerful prejudices which it had to encounter from the sanction of time and of great names, must allow it was new, and that the author has from its importance a title to rank in the first class of eminent discoverers, ancient or modern.

His discovery showed, that in most animals the blood circulates in arteries and veins, and through the medium of one, two, or of more hearts: that in arteries it moves from the trunk to the branches; and that, meeting there with the branches of veins, it returns in a languid stream to the heart; that the heart communicates a new impulse; that it drives it on to the trunk of the arteries; and that the arteries, by the thickness of their coats, exerting a force, do push it onwards again into the veins.

In every part of this circulating course, there are valves situated where it is necessary; they are meant to prevent the return of the blood; they are at the beginnings of the great arteries, and are found in different places of the veins where their feeble action requires to be assisted.

The veins, before they enter the heart, generally expand into a thin muscular sac, which is called the auricle. It receives the blood while the heart is contracting; and, when the heart admits of dilatation, contracts itself, and throws the blood into the ventricle.

We have here called the ventricle a heart: though what is usually meant by the heart be a ventricle and auricle; or sometimes a ventricle and two auricles, where the veins approach in different directions, and, without bending to meet one another, expand at two different places. Two

PHYSIOLOGY.

hearts are sometimes united, so as in appearance to form but one.

From our having mentioned more than one heart, it will be supposed that the modes of circulation are various. In some animals the heart throws its blood to the remotest parts of the system; in other animals it throws its blood only into the respiratory organs: from these organs it is collected by the branches of veins; and these branches, uniting in a trunk, convey it to an artery, which renews the impulse, and acts as a heart. In a third set of animals, the blood from the respiratory organs is carried by the veins to another heart; and this second heart, united in the same capsule with the first, distributes the blood by the channel of its arteries to the several parts. In the human foetus, and the foetus of those animals which have two hearts, a part of the blood, without taking the passage through the lungs, proceeds directly from auricle to auricle. In amphibious animals, the auricular passage continues open during their life, and is employed, when the breathing ceases, under the water. In many insects, a number of hearts, or expansions which answer the purpose of hearts, are placed at intervals on the circulating course; and each renews the impulse of the former where the momentum of the blood fails. In the *Sepia Loligo* the two separate parts of the gills are each supplied by a heart of its own: the blood from both is collected into one; which by two arteries opening at two different parts, send it at once to the opposite extremities. In numbers of animals, the heart, like the stomach, is in the extremity opposite to the head.

After the discovery of the circulation, the most interesting object with anatomists was to demonstrate it in a clear, satisfactory, and easy manner. Harvey, to show it with every advantage that he could think of, was obliged to open animals alive; but whether the animals were dead or alive, the larger branches of the veins and arteries were only to be seen, and even these but in certain cases, when they happened occasionally to be full of blood. That admirable method, which is now observed in demonstrating the course of the circulation, we owe to the great anatomists of Holland who flourished in the last century. About 1664, Regnier de Graaf invented the syringe, which is now used; and, accompanied with a print, published an account of it in 1669. His injection was usually a thin fluid of a blue, green, or some other colour; this injection transuded through the vessels, allowed them to collapse by its general diffusion, and broke out through the first opening that happened in its way. A fluid which hardened after being injected, and which preserved the vessels distended, was a happier contrivance. This at first was either melted tallow or wax, of a colour suiting the taste of the anatomist. So early as the year 1667, the celebrated Swammerdam injected the vessels running on the uterus with ceraceous matter; and, jealous lest another should claim the merit of such an invention, he transmitted preparations, accompanied with plates, and with a full account of his method, to the Royal Society of London, in 1672. Soon after, his friend Ruysch acquired such skill in the art of injecting, that he has not been surpassed by any since his time. He discovered vessels in many parts where they were not supposed to have had an existence; and, contrary to the opinion of the great Malpighi, he showed that even many of the glands were entirely vascular; and that what had been supposed excretory ducts, deriving their origin from some follicle, were but termina-

tions of arteries continued: yet even Ruysch could not exhibit in all cases the course of the vessels so well as we do now. Another discovery was yet to be made for demonstrating their small capillary branches running through a part. This was reserved for the very ingenious Dr. Nicholls, of London; who invented the method of corroding the fleshy parts with a menstruum, and leaving the wax, as it was moulded by the vessels, entire.

From these researches, which evince circulation to be a function so general among animals, some are disposed to think it takes place in all living bodies. But notwithstanding the fashionable language of circulating fluids, of veins, arteries, and even of valves, in the vegetable structure; yet nothing performing the office of a heart, and nothing that seems to conduct fluids in a circular course, has been found in plants. In the vegetable kingdom, the chyle is distributed to all the parts from the numerous vessels which convey the sap; and these vessels, being fitted by their structure to carry the sap either downwards or upwards, from the branches to the roots, or from the roots to the branches, is the reason why plants inverted in the ground will send forth roots from the place of their branches. Even a similar distribution of the chyle takes place in some animals. In the human *tænia*, in the *fasciola hepatica* of sheep, and in most polypes, the chyle, without a circulating system, is conveyed directly to the different parts from the alimentary canal. The taste for circulation may at last subside. Till the business of absorption from the intestines was, of late, fully secured to the lacteals, we were wont to have also learned dissertations upon a circular motion of the bile. The jaunt which it took was not very cleanly; but it was social: it went with the faces down the intestines, and returned with the blood in the mesenteric veins.

GENUS IV.—Respiration.

This is one of the most curious as well as one of the most important functions of the animal economy: and it is at the same time one of those with which to this hour we are least acquainted as to its mode of action. It is that function by which atmospheric air is introduced into the frame and variously modified for particular purposes.

So essential is respiration to the system, that snails, chameleons, and some other animals, can live for years upon air alone. We have seen a chameleon that lived and was vigorous for twenty-two months without any food, and which might have continued to live much longer but for an unfortunate bruise by a fall.

Other phenomena equally demonstrate the importance of air to the living body. The frog leaps away wanting its heart; it survives the loss of the greatest part of its spinal marrow. Without its head, it lives for some days, and its heart continues to circulate its blood. Spallanzani took one from the back of a female, cut off his head, and, after performing this whimsical experiment, saw the gallant return to his mistress, grasp her in his arms, and finish the task which he had begun. And Borelli found, that eels and serpents, though their bodies be opened, and the whole of their viscera be taken out, are able to move for a day after; and yet notwithstanding, in all these animals, the life is observed to be suddenly extinguished when the all-vivifying air is excluded. Even the smallest insect has died, and the plant lost its vegetative power, when retained for any while in a vacuum. The fish itself, when placed under the

PHYSIOLOGY.

Exhausted receiver has started anxiously to the surface of the water in quest of fresh air; and, finding none, has sunk to the bottom and expired in convulsions.

If objections should be made to these trials performed in a vacuum; if it should be said, that under the receiver the shrivelled fruit swells and turns plump, that the body of the frog is strangely inflated, that its turgid eyes grow prominent in its head, and that thin phials corked full of air are broke by its expansion; still there are facts which do not admit of the like equivocal interpretation. All living bodies will die in the air which they have respired; and when ice covers the whole of the water, many of the fishes are known to perish; or, if an opening be made in the ice, to hasten to the air, and, rather than retire, quietly suffer themselves to be caught.

The recent experiments of Mr. Brodie, upon this subject, are highly curious, and altogether pertinent to the present point. Animals pithed, or having the spinal marrow divided at its upper end, are well known to die as rapidly as if altogether decapitated; but if preparation be made at the time of being pithed for continuing an artificial respiration, by alternately inflating and exhausting the lungs by a small pair of bellows, the animal, instead of dying immediately, may be made to live several hours; and the action of the heart and the general pulsation of the arteries will continue with little interruption or diminution of strength: and the very same effects follow if the head be entirely taken off, provided the arteries leading to the head be properly secured. These experiments were repeated in a variety of instances, on dogs and rabbits, and with uniform results. The reader will find them detailed in the Phil. Trans. for 1811, forming the Croonian Lecture.

To this general dependence of life upon respiration there occur but few things like an exception; these are, some serpents and worms and crustaceous animals found alive in the hearts of stones, some insects that were found in wood, and a number of toads which in different places have been taken from the hearts of trees and of rocks, where they left an impression, and where they were supposed in some cases to have lived for centuries without air. These facts, real or pretended, have been the cause of much speculation. Some philosophers, who imagine that nature is always obliged to act agreeably to those ideas which they have already formed of her laws, are, notwithstanding the high authorities by which some of these facts are attested, disposed to doubt them. General analogy, which regularly opposes singular phenomena, is upon their side; and without her concurrence, they will grant existence to no living body that will not submit to the old established modes of respiration. Others, again, who would not presume to dictate for nature, who have long experienced that she is not forward to obtrude her secrets, and who can believe that she may have still some to communicate, consider these facts as something new which she means to impart; and as one of the instances where she seems to deviate from general analogy, in adhering to her grand accommodating principle, by which she fits every living body for a certain range of varying circumstances.

These last, receiving the facts as sufficiently authenticated, have studied only how to account for them. When stones therefore were thought coeval with the world itself, they supposed their

toads to have sprung from the ova that were scattered through the earth at its first formation; they did not recollect that if the earth must have existed before these ova could have been sown, and that if the stones were coeval with the earth, the ova could not have entered their substance. When they afterwards learned that the consolidation of stones is an operation still carried on in the mineral kingdom, they acknowledged their ova to be less ancient, but did not perceive that all these ova involved suppositions that cannot be admitted by sound reason. For, how was an ova to grow without air and without food? and how particularly was it to grow with such a force as to make an impression in a solid rock? This would imply a power of expansion scarcely to be equalled by gunpowder, and which we ought not to be rash in ascribing to the nutritive effects of abstinence and nothing. Were it not for the toad, the expansion itself might have found a solution in a theory of the earth, which has cast all its stones in a foundry under the water, where the moisture might have rendered them apt to be formed with numerous cavities.

Perhaps the way to remove these difficulties concerning the toad would be to ascertain its mode of existence in the heart of the stone. Suspecting that the air communicated somehow with the solitary cell, we procured a toad that was crawling out from its den in the evening. It was put into a glass just large enough to hold it with ease. The mouth of the glass was filled with cork sufficiently close to retain water; the glass was then laid on its side, and the animal respired for several days without discovering signs of uneasiness; but supposing that air might still be admitted, the cork received a covering of wax, and the animal died ten hours after.

But are we certain that the admission of external air would remove the difficulty? We are not so positive now as we were upon this subject. In the summer months we recollect to have drowned frogs which were living in the fields, by keeping them some hours under water; but if we allowed them to rise to the surface, and to respire at pleasure, they became at last so accustomed to that element, that, if the temperature was not much above that of spring-water, they lay in the bottom not only for days but for weeks together.

In the winter season, it is well known that frogs are sometimes discovered in clusters below stones and under water in the neighbourhood of springs; and often seen in the bottom of ponds, marshes, and ditches, where water is collected, and the whole surface covered with ice. In this situation, we have frequently examined their sides and their nostrils, and can venture to assert, that they did not respire in the same manner that they did when on land: for, the moment that this animal is put under water, the palpitating motions of its sides and its nostrils are observed to cease; and Chaptal has seen them suspending respiration as it were at pleasure even when in air.

While they move, however, and exhibit indications of active life, we would not say that air is excluded. In the roots of plants, in aquatic worms, in polypes, and in the placenta itself, the same organs seem to perform the double office of lungs and absorbents. When under water, what are the functions of these organs in frogs and in toads? It is not disputed that in moist places they can live longest without food; and some phenomena which have been observed relating to this

PHYSIOLOGY.

subject appeared to us not unworthy of attention. In the beginning of the summer 1793, while we were making a few experiments on the nervous influence with some metals, a frog was taken out of the water in the dusk of the evening, and put into a deep and wide-mouthed glass till next morning: but next morning a quantity of water was found in the glass, the animal was dead, its mouth full of foam, and the greater part of its body covered with froth. The following autumn a boy came with a couple of toads wrapt up in tow. Till we had leisure to make our experiments, they were allowed to remain as they were for three days in the corner of a room. When taken out, their colour was pale, their bodies much swelled, and a quantity of water collected between the skin and the muscles. When held in the hand with their head upwards, the water was evacuated downwards by the anus. It was one of these toads that afterwards died when confined in the glass without air. Its body was put into a solution of madder for two days; and when the skin and muscles were removed, the bones, which are still preserved, were found red. A live frog in the same solution, though allowed to breathe, expired in a few hours. In three days its bones become of the red colour, but not so deep as that of the toad's. Another frog died in the solution; but the bones, from age or some other cause, did not receive the colour of the madder. In all cases the skins were found red.

As we know not how far the great accommodating principle of nature may be extended, perhaps the absorbents opening externally may in these animals sometimes supply the place of the lungs, as the lungs supplied the place of the gills which they used when tadpoles, and as the gills had formerly supplied the place of a placenta, or the primary absorbents, through which they derived their nourishment in ovo.

Those stones which inclose animals are known to be such as have gradually assumed the solid form, and those animals which have been inclosed are known to be such as in other cases have been subjected to the torpid state: but this state has not been examined with all the attention which it deserves. From this state, Bonnaterra says, in his introduction to Ereptology in the *Encyclopedie Methodique*, that it is impossible to rouse the animal by the loudest noise, the rudest shock, or the deepest wound; the internal motion is just sufficient to preserve the system from that decomposition to which animal substances are exposed. It retains only the form of what it was. It appears neither to live nor to grow; and the whole mass, if what is exposed to the air be excepted, is not sensibly altered while the torpor continues. All the senses are shut up; all their functions are entirely suspended; digestion is no longer in the stomach; all respiration has apparently ceased; and it has been doubted whether or not this function be in some cases at all retained. When the genial warmth, however, returns, in six, in eight, or in ten months, according to that variety of climates between the frigid poles and the tropics, the animal revives. But the question is, if the first circumstances in which the animal became torpid had been artificially or naturally continued, how long in this way might the different functions of life have been suspended; and how far are we warranted by the analogy of seeds and of eggs to lengthen this period of their existence, without supposing a decomposition or destruction of organs?

Experiments must tell what are the limits which nature has here prescribed to herself. New eggs, when covered with varnish, or placed under the exhausted receiver, are secured against the attacks of corruption. Bomare, in his Dictionary, has mentioned three, which protected from air, were found fresh in the wall of a church after a period of 300 years. And if it be true that a snake found in a block of marble died as soon as exposed to the air, or if the parts in contact with air be the only ones which in torpid animals appear to be changed, it would seem probable that a total exclusion of this varying and active element would tend more to the preservation of torpid animals, in certain instances, than a free admission, which, in those cases where all vital functions have ceased, is regularly found a principal agent in their dissolution.

M. Herissant of the French Academy was the first philosopher who, by means of experiment, thought of interrogating Nature herself upon this subject. On the 21st of Feb. 1771, he with great accuracy shut up three toads from the air, two of which were taken out alive on the 8th of April 1774. Daubenton says, after a period of 18 months; but in this instance we depend more on the friend of Fontana, who has mentioned the dates. The two toads were again enclosed, and Herissant died before there was a second inspection. Daubenton says, that when taken out their bodies were hard and shrivelled, and their whole moisture totally absorbed. A fourth toad that had been inclosed was heard to croak whenever the box in which it was confined happened to be shaken. Since that period the practice is common of confining snails in a sealed phial, where they exist in torpor for years.

These phenomena still excite wonder; but to wonder less, and examine more, would sooner procure us that information which we are wanting. In these observations concerning toads, have no circumstances been overlooked? Has it been determined whether they lived in the heart of stones, or, existing merely in a torpid state, had come alive when exposed to air? We have seen a toad that was dead for two days; its body was opened; its heart was seen motionless; but, exposed to air, in a few seconds it began to beat. Considering the complex function of absorbents, we perhaps might conceive how a toad could live in the clefts of rocks, or the hearts of trees, where there is moisture; but has it yet been determined whether all stones in which toads have been found supplied them with moisture? We at least are certain that they did not absorb the animal fluids, like the plaster used by the French academicians.

One of the toads was heard to croak after being inclosed. In making their experiments, has it, therefore, been thought a matter of indifference by the French philosophers, whether the animal was immured alive in the full exercise of all its functions; or existing only in its torpid state? And with respect to this singular state, (might not the questions be fairly put?) have its several kinds, have the causes which induce it, or those degrees to which it may be carried in different animals, been yet ascertained? Is not our knowledge of the torpid state at this moment principally the result of casual observation? Has it not been oftener than once supposed that the torpor of all animals is similar, or takes place to a similar degree? Have not torpid animals been therefore spoken of in general terms? and has it not been asserted that they retain a portion of heat and internal motion?

PHYSIOLOGY.

though some have been found congealed in the ice, and many been dried to such a degree that they could be revived only by moisture.

"That snakes and fishes, after being frozen, have still retained so much of life as when thawed to resume their vital functions, is a fact," says Mr. Hunter, "so well attested, that we are bound to believe it." How came it, we would ask, that fishes which had been frozen by this truly ingenious physiologist never recovered? He recovered parts of different animals which had been frozen. Had the snakes and fishes of which he had heard been only partially congealed in the ice? or had the fishes which he selected for these experiments been properly chosen? or may all animals with equal fairness be made the subject of such experiments? and may all transitions from heat to cold, and from cold to heat, whether slow or rapid, if not in the extremes, be viewed as nearly of the same consequence? Are all seasons and conditions of body equally favourable to this state of torpor? and will these causes which induce torpor by operating externally in the months of autumn be able to continue it by the like action in the months of spring? We can answer, No.

It has been said that animals subsist in their torpid state by the reabsorption of fat. Has it therefore been proved that all animals, not to say living bodies, are possessed of fat? or, if they be, has it been demonstrated that they have a superfluous quantity to be reabsorbed? Has it been shown that their waste of fat is always occasioned by this reabsorption? or has this reabsorption in all cases been of that kind to counteract the effects of abstinence? If it has not been proved that all animals contain fat, and that this fat is reabsorbed in their torpid state, ought not the general assertion to be limited? Granting that in many respects it were true, have not philosophers been here amusing themselves with logic, where they could have been employed in making experiments? Have they not ventured to give us conclusions, where we had reason to expect facts? And, on this account, has not their conduct been somewhat similar to that of navigators, who, sailing along the coast of Patagonia on one side, and observing a few men of an uncommon stature, have from thence peopled the whole of the country with a race of giants? or rather to that of some calculators, who, from seeing a few parts of a continent, have ventured to give a map of the whole, to describe kingdoms that are yet unexplored; and, by their skill in addition and subtraction, to exhibit the figure, the extent, and proportion of lands unknown?

Leaving therefore the torpid state as one of those subjects with which we at present are little acquainted, and of which we therefore cannot speak with certainty in the general abstract language of science; it will naturally be asked, in what respect is air so necessary to all living bodies in their active state, and how contributes it to the regular performance of the different functions?

The ancients, who were led by the heat of the blood to suppose a vital spark in the heart, who had noticed the appearance of smoke in the breath, and who had observed that fire was extinguished when deprived of air, naturally inferred that the end of respiration was to support their imaginary flame, to ventilate the blood in the arteries and lungs, and to keep alive their vivifying spark. They were far, however, from being agreed as to the manner how this was effected. Some were of opinion that a certain principle of the air was absorbed, to which they gave the name of the pro-

vender of life, or the food of the spirit; while others were persuaded that the air acted as a refrigeratory, and was merely intended to moderate the fire, to assist in expelling the fuliginous vapour, and preserve the system in an equal temperature.

The moderns, who, after all their researches, have been unable to discover this vital spark of the ancients, are more puzzled to assign an adequate cause for the heat than for any cold which they discover. To account for this singular phenomenon, they have been ransacking nature for causes; and, perceiving that putrescence, mixture, and friction, are in many instances accompanied with heat, have thence conjectured that they sometimes operate in producing the warmth of the living body. But these are theories which have been imported from the hot-bed, the laboratory, and mechanic's shop, and which have never yet been countenanced by physiological facts and observations. No one has been able to show that putrescence exists in a healthy state, except in the faeces: no one has proved that any mixture which regularly occurs in the alimentary canal or vessels, generates heat; and though friction has been a favourite hypothesis, yet those circumstances, in which it evidently produces heat, have not been discovered in the living body; and it is not determined whether it be there a friction of the fluids, a friction of the solids, or a friction of the fluids and solids together.

Of animal heat the most rational theory, we think, is one which properly belongs to the last century; it is confirmed by modern discoveries, and ascribes this heat to respiration. Many had observed, that those animals which respire most have the warmest blood. Lower demonstrated, that this blood received a new and a brighter colour in passing through the lungs. Verheyen and Borelli both proved, that the air lost something by coming in contact with that organ. Mayow showed, that this something which the air loses is contained in nitre. Experience taught the workers in nitre, that this something was absorbed from the air: and Verheyen remarked, that it is also absorbed by the lungs; and is probably that which maintains combustion, which qualifies the air for giving support to animal life, and imparts to the blood the vermilion colour.

How well the whole of this reasoning was founded, is proved by the late discoveries of Priestley and other chemists. There is now obtained, in a separate state, an aerial fluid, which maintains both life and combustion, and gives a vermilion colour to the blood. It is extracted in a very large quantity from nitre; is one of the component parts of the atmosphere, and the vital principle of that element; without which, in most animals, life is extinguished. From some phenomena which happen in combustion, it has been termed principium sordile. It was called dephlogisticated air by Priestley, the first discoverer: as the great acidifying cause in nature, the French nomenclature has given it the name of oxygenous gas; and, as one of the causes on which the existence both of fire and of life depends, it is named empyreal or vital air.

Late discoveries have shown farther, how this air may in respiration produce heat. From the most accurate investigations, it appears that caloric, or the principle of heat, is a distinct substance in nature; that it combines with different bodies in different degrees; that it is the cause of fluidity in all; and that, in proportion to that capa-

PHYSIOLOGY.

city which they have for it, and to that distance at which they are removed from the fluid state, the more or less caloric they contain. Aeriform bodies being all therefore exceedingly fluid, it must be evident, that when they are fixed or condensed in the blood, and made to approach nearer solidity, a quantity of heat must be evolved. A part of this is very plainly evolved in the lungs where the air is absorbed, as appears by the breath; and a part evolved by the action of vessels, as appears from nearly an equal heat over the system, from the partial heat of a morbid part, and the sudden transition from heat to cold, and from cold to heat, over the surface, when the vessels are affected by either internal or external stimuli. When the heat, thus evolved by the gradual fixation of that body with which it was combined, has been successful in making its escape by the lungs and integuments, the blood returns in a dark and a sluggish stream by the veins, and mingles again with the genial fluid, which before gave it spring, activity, and life.

Of that oxygen which remains in the system part is employed in forming different saline combinations and supplying the waste occasioned by that constant reabsorption; which, from many experiments that have been made with solutions of matter, is known to take place in the solid bones. The use of that oxygenous gas which returns with the breath, is best understood after knowing its affinities. Its basis oxygen, combining with hydrogen, which is the basis of inflammable air, forms water; and, combining with carbon, the carbonic acid. It carries, therefore, back with the breath a part of the carbon produced by the slight combustion of the blood, and a quantity of hydrogen arising from the watery fluid decomposed.

But oxygenous gas does not alone enter the lungs. Of 100 parts of the atmosphere, but 28 are oxygenous gas, $\frac{100}{300}$ is carbonic acid, and 72 are azotic gas. These last, though intended chiefly for other beings different from man, which are in immense numbers on the globe, but which, like him and the nobler animals, are not formed to breathe the empyreal air, must notwithstanding be of some important and essential use to all living bodies. It has accordingly been found by experiment, that pure and unmixed oxygenous gas cannot be breathed for any very considerable time without danger; that some azote is contained in the blood, and has been extracted from the muscular fibre, when properly treated with the nitric acid. According to Berthollet, five of its parts with one of hydrogen form ammonia, or volatile alkali; which dispels the glandular tumours of the body, and prevents the coagulation of blood and the thickening of mucus which arise from acids. The azotic gas may therefore in part unite with hydrogen, may prevent the coagulation of serum, the catarrhus formation of viscid mucus, and many combinations that oxygen might form, injurious to the system. The carbonic acid, which is $\frac{28}{100}$ of carbon and $\frac{32}{100}$ of oxygen, may also be necessary in regulating the effects of the other two. In aerated water, its uses are very generally known: it allays the pain of the urinary bladder when excited by calculus; it has been employed in the cure of wounds, and been thought useful in the pulmonary phthisis. It is generated in the lungs of those animals which respire oxygen. In small proportions it favours the growth of the vegetable tribes. These tribes readily decompose it; and, with the addition of other prepared oxygen from water, restore what

is pure to the general mass of the vital fluid, that plants and animals might thus live by the mutual performance of kind offices.

We return again to animal heat. Every theory that pretends to account for animal heat, ought also to account for that singular equality of heat which the system preserves, or endeavours to preserve, in different temperatures. The above theory explains it simply in the following manner.

Venous blood, if exposed to the air, is known to absorb a portion of oxygen, and assume that colour which it has in the pulmonary veins and aorta. Suppose an absorption of a similar kind taking place in the lungs, a fact which may be proved by decisive experiments; it is plain that the oxygen by this absorption must recede from its gaseous or fluid state; that a quantity of heat must be therefore evolved, which, along with the heat of the reffluent blood, is carried away by that vapour which issues from the lungs. In the course of circulation, the oxygen will naturally incline with hydrogen to form water; it will tend likewise to the formation of many other compounds; and, as it enters into new states, and is farther removed from gaseous fluidity, it must still be giving out a portion of heat. If the surrounding temperature be cold, this separation will be easily effected. The caloric will, in that case, be greedily absorbed from the interior surface of the lungs and exterior surface of the whole body. The oxygen, meeting with the necessary temperature, will readily pass into new forms; and the venous blood, returning to the lungs, will demand a supply which will be either greater or less according as the cold, by favouring the escape of the caloric, and promoting new combinations with oxygen, had removed it from the point of usual saturation.

The gradual evolution of heat is a proof that the temperature must be sometimes reduced before the oxygen can properly enter into all the usual combinations of the system. Suppose the body then to be placed within a hot circumambient atmosphere. This atmosphere, if warmer than the animal, will be more apt to part with heat than to receive it; and the oxygen absorbed, being thus unable to dispose of its caloric, will be prevented from passing into those combinations and forms where heat is evolved. The venous blood will therefore conduct it back to the lungs, and make a demand for a new supply; but proportionally less according as the hot circumambient air, by preventing the escape of the caloric, and the usual facility of new combinations, has confined its removal to a smaller distance from the point of saturation.

In this last case the thing principally entitled to notice is a very curious effort of nature to resist the growing increase of heat. In the warm atmosphere, as during violent muscular exertion, the exhaling vapour is commonly discharged in a greater quantity from the surface of the body; and consequently the heat furnished with an excellent temporary conductor, that in some measure counteracts the dangerous effects from without.

After all, the reader is not to suppose that he here has received a general theory of respiration. All living bodies are not supported by the same kind of aerial food. Oxygenous gas has indeed been honoured with the flattering appellation of vital air; and nitrogenous gas been usually distinguished by that degrading epithet azotic; a word which signifies destructive of life. But though man, and all the warm-blooded animals that have yet been examined, may die in respiring

PHYSIOLOGY.

the nitrogenous gass, this gass, however, which constitutes more than two-thirds of the whole atmosphere, may in general be called the vital air of the vegetable tribes, and of not a few of the orders of insects which thrive and live in it. For while man, and others which respire as he does, emit both the hydrogen and carbon, and return the nitrogen not sensibly diminished; most vegetables and many insects eagerly inhale them, and emit oxygen as noxious or useless. These effects are the indications of a radical difference in constitution. Even the fibres of those living bodies which exhale oxygen, will, after death, attract it so powerfully, as to decompose the nitric acid; but those bodies which inhale nitrogen have so very weak an affinity to oxygen, and so strong a one to some of the bodies with which it is combined, that they can easily decompose water and carbonated air.

What fishes respire is not ascertained. Neither the change of the air, nor of the water which they occasion when in close vessels, have, so far as we know, been fully examined. Chaptal is assured, that, like other animals, they are sensible of the action of all gasses. Fourcroy says, that they do not generate the carbonic acid; and that the air which Priestley and he found in the air vesicles of carp was nitrogen gass. Their thermometrical heat is so low, that in Daubenton's table they are reckoned among the cold-blooded animals.

The temperature of plants is still lower. The heat of a tree which the very ingenious Hunter examined, though several degrees above that of the atmosphere when below the 56th division of Fahrenheit, was always several degrees below it when the weather was warm. When taken out, the sap was observed to freeze at 32°, while in the tree it would not freeze below 47°. The very profuse perspiration of vegetables greatly moderates the heat in their surface; and as air which absorbs moisture expands, and becomes thereby specifically lighter, there is a regular current produced, and evaporation rapidly promoted by the dense air displacing the rarefied.

To adopt here a general language with respect to the heat which is developed in all living bodies, it is proportioned to the quantity of matter which is by means of the vital powers reduced to a state more nearly approaching solidity; to the kinds of the substances which are reduced, and to the degrees and kinds of the reduction.

In all living bodies there appear to be certain degrees of heat, peculiarly fitted for carrying on their various economical operations. What these are, in the different kinds of plants and animals, is not known. The bear, the hedge-hog, the dormouse, and the bat, may probably not digest when reduced to 70°, 75°, or 80°. The frog, however, will digest at 60°; and the birch before it arrives at 47°. It would seem that respiration, besides imparting aerial food, was intended to preserve and regulate these different degrees of heat. It raises the heat after a meal; it suffers it to fall in the time of sleep; it withdraws the supply when the atmosphere is warm, and increases it again when the atmosphere is cold. It should therefore be remembered, that heat merely is not the object which is solely aimed at in respiration. All living bodies have their congenial degrees of heat. The regulation of these is important: on the one side, it prevents the dissipation, on the other the coagulation, of their fluids; it preserves the living power of their organs; and, by a natural and proper temperature, assists their action in mixing, composing, in decomposing, and in variously pre-

paring the different parts for secretion, excretion, absorption, reabsorption, and assimilation.

As various fixations of the vascular fluid are regularly taking place in the different parts of the living body, and as air is not the only fluid concerned, it would almost be unnecessary again to observe, that the whole of the heat is not evolved in the lungs, nor the whole that is evolved disengaged from air.

It may farther be remarked, that the whole of the air does not enter by the lungs; much is contained in the liquid and solid parts of the food. It is extricated often in the process of digestion; and when the organs are vigorous and healthy, is made subservient to the general economy. If the organs, however, should happen to be languid, it scorns their authority, which cannot be enforced; from being friendly, it soon becomes inimical to the system, and, threatening danger, accumulates not only in the stomach and intestines, but in other cavities. It has been found in the cellular membrane; in certain vesicles formed for itself; in the uterus; in an abscess; and in gun-shot wounds: it has sometimes burst from the vagina with a sort of noise. And in a nephritic complaint of a horse, we have observed it flowing in a stream from what the farriers denote the sheath.

In some kinds of aquatic plants, in eggs, and in a variety of fishes, there are certain vesicles containing air, which seem to have certain necessary functions allotted them by nature. In the plants and in fishes they were once supposed to have been wholly intended for swimming. It was remarked, that those fishes which remain constantly at the bottom of the water have no air-vesicle; and that a fish whose vesicle was burst by means of the Torricellian vacuum, though it lived for a whole month after in a pond, was never able to rise to the surface. The practice, however, which some fishes have of ascending at times to inhale air, and descending after their vesicle is filled; the communication which, in some fishes, this air-vesicle has with the stomach; that power in the pigeon and some other birds of introducing air into the crop; and lastly, the air which is uniformly found in impregnated eggs—would tempt us to believe that these natural collections of air, with their other uses, may perform some essential service in nutrition.

Having explained the general intention of respiration, we are now to inquire, what are the kinds of respiratory organs, and in what manner their functions are performed? The preceding table has in some measure made us acquainted with this subject. Some animals breathe by a trachæ and lungs; insects, by either stigmata or trachæ, opening into air-vessels; plants, by air-vessels and leaves; fishes, and numbers of the watery element, if they do not breathe, at least receive air by the gills; the fœtus in ovo, the polypus tribe, and many more organized bodies, by the same organs which convey their food.

The absorbents appear to be the first and most general way by which living bodies are supplied with air: the mouths of these vessels are like small tubercles, scattered over the body of the insect while wrapt in its membrane. In the horse and the bird they are blood-vessels spreading on a membrane, and deriving nourishment from the uterus or egg, that had been itself nourished by absorbents. In a cow, they are vessels which, spreading on a membrane, terminate in glands; these glands being opposite to others which adhere to the uterus; and the membranous and uterine glands,

PHYSIOLOGY.

when in contact, inclosing a third gland like a kernel. In man, they are vessels spreading on a membrane, and entering a large glandular body called the placenta. In the mouse and the hare, they are likewise vessels branching on a membrane, and entering a placenta: this placenta, when it happens to be fixed, receives large veins from the parent, and which may be either inflated or injected from the cavity of the uterus.

Those which are properly respiratory organs exercise not their function till circulation and nutrition are begun: though, if the observation of Garman be just, that the air may become a real food for the class of spiders; or if it be true that the larvæ of ants, as well as of several insects of prey, increase in bulk, and undergo their metamorphoses without any other nourishment than air, this law is not universal. It may, however, be doubted, whether some moisture be not adsorbed. With regard to the ant, we have reason to suspect that the observations on which such a conclusion was founded have not been accurate.

Not only are the respiratory organs thus late in exercising their functions; in many vegetables a great part of them is annually renewed, and laid aside in the torpid state. In those insects which undergo the most remarkable kinds of transformation they suffer a change; and in all those animals which spend their earlier days in the water, and afterwards come to live in the air, they are altered in kind.

In all living bodies the proper function of one part of the respiratory organs is, to secrete from the water or air that particular aeriform fluid which mingles with their juices, and which is necessary to life and nutrition. In many cases these organs are placed externally, and are always in contact with the air or water from which they secrete. In other cases they are lodged internally; and air or water are then alternately admitted and expelled by varieties of organs which serve as auxiliaries.

The plants secrete their aeriform fluid from water and air. They receive air along with the liquids of their absorbents, which open on the roots, the trunk, and the branches, and upon the inferior surfaces of leaves; or if nature has plunged these leaves under water, the absorbents open and imbibe their fluids on both sides. In many, however, the upper surface of the leaf is intended to inhale air. Bonnet observed, that when this surface was applied to the water the leaf died soon; but that when the lower surface was applied, it lived for months. It has also been remarked, that the upper surfaces of some leaves will repel water; and that the death of the leaf will ensue when its breathing pores are obstructed with oil. We hence learn why aquatic plants rise up to the surface of the water and spread their leaves in the open air: and as it is proved by Ingenhousz and others, that the respiration of many leaves is assisted by light, we see a reason why plants growing in a dark room turn to the place where light is admitted; why the flowers and the leaves of many plants follow the diurnal course of the sun; why the branches of trees, which require much light, die when placed in a thick shade; why moonshine in autumn contributes so much to the ripening of grain; and why leaves and branches are arranged in such a manner as least to intercept that quantity of light which nature has allotted to the genius of each.

The respiratory organs, which are similar either to the gills of fishes or the lungs of man, can hardly here claim a description, as their nature and forms are so generally known. There is one

circumstance, however, in birds which arrests our attention; the cells of their bones, and the numerous vesicles of their soft parts which communicate with the lungs, have been deservedly a matter of surprise to most physiologists. In accounting for their use, the ingenious Hunter supposed that they lessened the specific gravity and assisted flying; that being the circumstance which he thought most peculiar to birds. Learning afterwards that they were in the ostrich and not in the bat, he supposed that they were appendages to the lungs. In amphibious animals, in the snake, viper, and many others, he observed, that "the lungs are continued down through the whole belly in form of two bags, of which the upper part only can perform the office of respiration with any degree of effect, the lower having comparatively but few air-vessels." In these animals, the use of such a conformation of the lungs was to him evident. "It is in consequence of this structure," said he, "that they require to breathe less frequently than others." From this reasoning he naturally inferred, that the motion of flying might render the frequency of respiration inconvenient; and that a reservoir for air might therefore become singularly useful. The bat and the ostrich, however, are here as formidable objections as before. The bird respire frequently when at rest, and when it flies to our bosom from the hawk; that frequency seems to have been increased by what is a general and a common cause, an increased degree of muscular exertion. Had air-cells been intended merely to prevent the effects of a rapid motion on respiration, we might expect to see them in greyhounds and a number of quadrupeds, much more readily than in some birds whose flights are neither rapid nor long.

This great physiologist was not aware that the circumstance most peculiar to birds was not their act of flying, but their feathers, which contain a large quantity of air, and which require a regular supply, whether they soar on the wings of the eagle, or remain on the ground attending the ostrich.

Both in amphibious animal and birds, the air of the vesicles has passed the respiratory surface of the lungs. In the pulmonary tubes and vesicles of insects, it is only proceeding on its way to be respired. Would it be worth while to inquire whether vegetable substances, and those which are called corneous in animals, require a different preparation of air from what is the common preparation of lungs? whether hair grows best, or the cuticle thickest, over soft parts that are cellular and spongy? and whether the animals that bear horns have larger sinuses in the frontal bone of their cranium than others? From the general diffusion of air through the birds, and the situation of their vesicles beyond the lungs, it would appear that the pulmonary viscus in these animals does not respire or secrete air for the whole system; and we are certain, that in plants and insects, most parts respire the air for themselves, and that there is no particular part appointed to secrete air for the whole.

We here speak of respiratory organs, as those which secrete an aeriform fluid from water and air; but our language probably had been more accurate had we called them the organs in which an aeriform fluid is absorbed by their liquid contents, as these flow by, wholly or in part, in their course through the system. It was long denied that any absorption of the air took place from the pulmonary surface; and speculative reasoners had attempted to prove that

PHYSIOLOGY.

no air could pass to the blood through the membranes of lungs, because air had refused upon some occasions to pass through pieces of wet leather that had been exposed to it for that purpose. Borelli, however, endeavoured to show how air in the lungs might mingle with the blood, and how some always disappeared in respiration. There are few doubts now entertained on this subject. Venous blood inclosed in a bladder by the celebrated Priestley discovered such an attraction for oxygen, that it absorbed the æriform fluid through all the coats of the resisting medium, exhibiting an instance and beautiful illustration of the chemical affinities which take place in this function.

GENUS V.—*Secretion.*

This is a function by which a part is separated from the whole, and generally with some change of its qualities. In the case of nutrition it is observed that all parts secrete for themselves; and that some few, as the lungs, the stomach, the vessels, and the nerves, officiate besides for the general use of the whole system. If all the ingesta were to remain and to be assimilated, the body would go on continually increasing. But living bodies are constantly in a state of waste and repair. In most animals part of the ingesta is carried off by evacuation, without having entered the mouths of the absorbents; part, which enters the absorbents and veins, is thrown off by exhaling arteries or the urinary passage: and experiments with madder prove that the lymphatics, besides originating from all the cavities and carrying back the lubricating fluids, do enter the substance of the hardest bones, and convey particles that had been assimilated back into the blood.

This office has not been generally ascribed to the absorbents; nor has it been very generally supposed that the blood receives the excrementitious matters of the system, and that one intention of the circulation was either to return them for re-assimilation, or to discharge them by exhaling vessels or by the kidneys. Decayed parts, however, are discovered in the fæces evacuated by the intestines, in the clouds, the sediment, and colour of the urine, and by the smell of the perspirable matter. The two last, on certain occasions, and for some time, have often supplied the place of one another; and all the three, the fæces, the urine, and perspirable matter, we have reason to believe, are remarkably distinguished by two kinds of odour; the one peculiar to the whole species, the other peculiar to the individual. By the perspirable matter which adheres to the ground, and of which the odour is diffused by moisture, the dog not only distinguishes a man from any other animal, but is able to trace his master through a crowd.

The natural evacuations of plants, and of some few animals which feed by absorbents, are all by perspiration or exhaling vessels. The urine in quadrupeds is before emission collected in a vesicle, and thence carried off by the genital organ. In birds, and in a number of fishes, the ureters empty themselves into the rectum, and their contents are evacuated with the fæces.

Independently of being used to denote the function, the word secretion is sometimes employed for the matters secreted. In this sense there are various secretions. Besides the fæces, the urine, and the sweat, and the vapour from the lungs, which are excrementitious, there are secretions which answer useful purposes in the system. Of these the most important and general are the bile,

the saliva, the gastric juice, and the pancreatic; which assist in digestion; the lymph and the fat, which lubricate the parts; the mucus, which protects them from acrid substances; the nervous fluid, which forms a very conspicuous link between body and mind; the seminal fluid, employed in generation to propagate the species; and the lacteal, intended for some while to support the young after they emerge from the fetal state.

The saliva is a fluid that mixes with the food in the time of mastication. In man it is secreted from the parotid, the sublingual, and submaxillary glands; it is watery and somewhat viscid; it is found to retard and moderate fermentation; it has sometimes a tendency to form calculi like the urine. By these concretions it incrusts the teeth and sometimes obstructs the salivary ducts. It is the seat of the rabies canina.

Upon first examination the gastric liquor seems to possess a solvent power upon animal and vegetable substances, without any great preference of affinity. The reason is, it varies according to the nature of the aliment; it is sometimes acid, sometimes insipid. Brugnatelli has found (says Chaptal) in the gastric juice of carnivorous birds and some others, a disengaged acid, a resin, and an animal substance, united with a small quantity of common salt. The gastric juice of ruminating animals contains ammoniac, an extractive animal substance, and common salt. In our time the phosphoric acid has been found disengaged in the gastric juice of the graminivorous kinds.

The bile secreted by the liver is glutinous or imperfectly fluid like oil, of a very bitter taste, a green colour inclining to yellow, and froths by agitation like the solution of soap. Its constituent principles are water, a spiritus rector, a coagulable lymph, a resinous oil, and soda. The resinous part differs from vegetable resins, because these do not form a soap with fixed alkalis, because they are more acrid and inflammable, and because the animal resin melts at the temperature of 40 degrees, and acquires a fluidity similar to that of fat. From fat it differs in not being soluble in cold alcohol, in which respect it approaches to spermaceti, which alcohol cannot dissolve without heat.

Bile, like other soaps, removes spots of oil from those substances to which they are adherent; when its passages are obstructed, the motion of the intestines becomes languid. It is neither alkaline nor highly putrescent. In putrefaction it yields something of a musky odour; the fossil alkali precipitates from it a green sediment; and with distilled vinegar it produces a mixture neither acid nor sweet. Like saliva and urine, it has a tendency to form concretions which are called biliary calculi or gall-stones. They are sometimes found of an irregular texture, of a brown, black, yellowish, or greenish colour. They sometimes consist of transparent crystalline laminae, like mica or talc, and are sometimes radiated from the centre to the circumference. They are always inflammable, of a more solid consistence than the generality of animal oils, and resemble spermaceti both in their solidity and crystallization; they are soluble in ardent spirit when assisted by a moderate heat: the warm solution, when filtered, deposits by cooling a number of laminated white brilliant crystals, such as Poulletier de la Salle found in the bile, and which have been compared to the salt of benzoïn, the concrete acid of borax, and to spermaceti. Many of their characters indicate that they are a substance of the same nature with the last men-

PHYSIOLOGY.

tioned. Fourcroy found that the substance of which these crystals are composed exists not only in the crystallized gall-stones or bile; he observed it to a very considerable degree in a human liver which had been exposed to the air for several years, and had lost its volatile parts by putrefaction. He detected it also in a saponaceous form in bodies which had been many years buried under ground; and Dr. George Pearson has artificially converted the muscular fibre into a substance of a similar kind, highly inflammable, and resembling spermaceti.

The pancreatic juice resembles the saliva, and was examined in the last century, with a good deal of care, by De Graaf and Swammerdam. It has often been observed forming stony concretions.

The lymph consists chiefly of water; but, like the serous part of the blood, contains a substance which is coagulable by heat, by acids, and by spirit of wine. It is found in the cellular membrane, in the ventricles of the brain, in the pericardium, on the surface of the pleura, in the abdomen, in the bursæ mucosæ, and in the joints under the name of synovia, where it has more than an ordinary degree of viscosity, and of the lubricating quality. Sometimes, when it stagnates in the sheaths of the tendons and bursæ mucosæ, it acquires a thickness, and forms indolent transparent tumours, which become at last gelatinous. It is secreted chiefly by arteries.

Animal fat is a substance of a nature similar to those oils which are called fat in the vegetable kingdom. Its colour is usually white, sometimes yellow, and its taste insipid. Its consistence is various in different animals. In cetaceous animals and fishes it is nearly fluid: in carnivorous animals more fluid than in the frugivorous: in birds, finer, sweeter, and more unctuous, and generally less solid than in quadrupeds. In the same animal it is more solid near the kidneys and under the skin than in the vicinity of the moveable viscera. As the animal grows old it becomes yellower and more solid; and in most animals is more copious in winter than in summer. In man and some other animals, it is collected in particular follicles of the cellular membrane, accumulated in great quantities in the groin, in the axilla, in the epiploon around the kidneys and around the blood-vessels: it is likewise secreted on the surface of the skin, which it protects from acrid substances, and where it sometimes concretes, often from a want of cleanliness, in the form of small worms. In cetaceous animals and fishes it is generally disposed in certain reservoirs, such as the cavity of the cranium and the vertebrae; in some it is chiefly confined to the liver; in serpents, insects, and worms, to the viscera of the lower belly, where it is disposed in small lumps, and only a small quantity found on the muscles and under the skin: in frogs it is collected in certain bags which diverge, as it were, from a common trunk, and seem like appendages to the ovaria and testes. In many places it seems to be secreted by organic pores, and under the surface of the skin by glands. It is accumulated from a diminution of perspiration, from the nature of the aliments, from morbid affection, and from idiosyncrasy. It is of the same nature as the fixed oil of plants; and Lorry has found a very striking analogy between it and the bile.

It is a bad conductor of heat, and preserves the warmth of those regions where it is situated. It is more adhesive and less apt to evaporate than water, and is therefore a better lubricating fluid. When

reabsorbed, it counteracts the saline impregnation if too copious; and its nutritive power is as three to one when compared to that of the muscular fibre. These properties may partly serve to explain its uses around the several branches of the blood-vessels in those parts which require warmth, and in those which are anywise exposed to motion. They will likewise account for its being more copious in winter than in summer; and for its being found in great quantities in the marmot, the dormouse, the bear, and those animals in general which are constrained to a long abstinence. It forms sometimes steatomatous tumours, and contains the sebaceous acid, which acts readily on lead, copper, and iron.

The vegetable fat is contained chiefly in the fruit; and is known by the names of fat oil, sweet oil, and oil by expression. It freezes in different degrees of heat, and varies according to the nature of the plant by which it is afforded.

The mucus is more viscid than the lymph, and is not coagulable by fire or alcohol. It is mild, not disposed to corruption, nor soluble in water. This secretion is performed by glands. These glands, in the pulmonary phthisis, secrete often a mucus that resembles pus, and occasions a suspicion of ulcers where there are none. Mucus is found in the nose, through the whole length of the alimentary canal from the mouth to the anus, in the aspera arteria, in the bronchia, in the kidneys, ureters, bladder, and most of all in the urethra. It forms hard stony concretions sometimes in the lungs.

The seminal fluid has been seldom the subject of chemical analysis. It is heavier than water, soluble in urine, deliquesces in air and with heat; it hardens with the fixed alkali, and is not coagulable by alcohol. It contains a number of animalculæ; and in the system in which it is secreted, it affects the passions, the manners, and the voice, the taste of the muscles, the secretion of fat, and the growth of the hair. In many fishes this fluid is contained in a sort of bags. In most animals it is secreted by glands, which are called testes, and is accumulated in the vasa deferentia, or where they exist in the seminal vesicles. Of these vesicles Swammerdam observed long ago, that in the scorpion they were probably adapted by nature to secrete a seminal matter different from that supplied by the testicles; they are largely (he says) supplied with glandules to answer that purpose, and consist of a considerably thick and spongy substance. Mr. Hunter since has endeavoured to show that they secrete a particular fluid in all animals.

So little are we acquainted with the nervous fluid, that some have doubted of its existence. The discovery, however, of Galvani, and the numerous experiments that have since been making on animal electricity, leave us not without all hope that something yet may be known of its properties, that will greatly illustrate several phenomena in the animal economy.

The lacteal secretion is generally confined to one sex, and is peculiar to the class of mammalia, though something similar may perhaps be secreted in the crops of pigeons.

It would be impossible here to enumerate or to tell the uses of all the different kinds of secretions in living bodies. We cannot enumerate all that we know without running into tedious detail. The essential oils, the camphor, the gums, the balsams, the resins, and many others, are various secretions of the vegetable kingdom. Each species of plant

PHYSIOLOGY.

and animal has generally some peculiar secretion; and this secretion in the individual has often some distinguishing quality, discoverable by taste, by colour, or by smell. These different secretions have likewise each their particular uses. We know the intention of the oily juice with which the bird dresses its feathers, of the glutinous fluid of the fish, of the viscid mucilage of the snail; we see the purpose for which the viper sometimes employs its virulent humour, and for which the cuttle-fish ejects its ink: but yet we know only in part.

The difference among the various secretions of the same system seem principally owing to a difference of stimulants, and to some difference in the action, the form and the irritable power of the secretory organ. Passions of the mind very often affect the secretions; and it frequently happens that passion and medicine affect one secretory organ and not another. It is therefore probable that the organs of secretion, and the smallest fibre is an organ of this kind—we say, it is probable that the organs of secretion, like the eye, the ear, and all the different organs of sense, are each affected in some measure by peculiar stimulants; as the stomach by hunger, the fauces by thirst, and the genital organs by venereal orgasmus.

Fermentative mixture, and some original impregnation of the organs, have also been brought to explain the several phenomena of secretion. We conclude with observing, that however much the various fluids of living bodies may differ in appearance, chemical analysis has generally reduced them to a water, a gluten, a saline impregnation, and an oil.

All living bodies are furnished with one, two, or with more integuments, which are prepared by secretory organs, and which are a defence against those injuries to which their situation is commonly exposed. Of these integuments, some prevent the dissipation of the fluids, some again resist acrid and corrosive substances, some are indigestible in the stomach, and some are seemingly incorruptible in the earth. By these properties they preserve seeds and the ova of insects for a number of years, waiting the change of soil or of season. They protect both from the action of weak membranous stomachs, and make those animals who choose to swallow them contribute likewise to their propagation. The gelatinous substance ejected by birds, and called the tremella-nostoc or starfall, we have lately found, by numerous experiments, to be a substance of this kind. It is nothing else than the oviducts of frogs, which, as the embryo in form of an egg moves along their winding canal, are intended by nature to secrete that transparent and viscid glare which constitutes the albuminous part of the ovum, and feeds and protects the embryo in water.

Some integuments are chiefly useful by their strength and hardness. The shells of the beetle are an excellent defence for the membranous wings which the creature is seen to pack up in folds when it inclines to creep into the earth. The shell of the snail lodges the intestines when the animal comes forth to search for its food, and it furnishes a safe retreat for the body when any danger is threatened from without. Some animals, confined to their shells, can open and close them by a muscular power; and some shells, like the scales observed on fishes and insects, are disposed into plates, so as to be no hindrance to motion. Several insects which spend a part of their time in the water always compose a shell for themselves where

it is needful. The usual materials are sand, straw, or mud, which they cement by a viscid secretion. The shells of most insects are corneous. Swammerdam found that cretaceous shells are composed of layers of indurated membranes, and that they are sometimes covered with a cuticle.

Some integuments are covered with feathers, some with hair or a thick down. Besides many other obvious uses of these coverings, they serve in general to repel insects; and, being but bad conductors of heat, maintain a genial and necessary warmth.

When the integuments are covered with prickles, they repel attacks by the strength of their points, or by the venom which they infuse, as the stings of nettles and the downs of some insects and plants.

When they are moistened with a viscid secretion, they preserve the necessary softness of the parts, prevent evaporation, resist acrimony, enable plants to destroy their enemies, and assist the snail in performing its motions.

Both plants and animals, but particularly the former, are often protected by an odorous effluvia from their integuments. This effluvia is the finer part of their volatile oil, always inflammable, and so subtle, that the continual emission of it from wood or flowers does not sensibly diminish their weight. To this fragrance it is owing, that the deadly nightshade, the henbane, hounds tongue, and many others, are seen on almost every high road untouched by animals. The mancinelle-tree of the West Indies emits so very dangerous vapours, that the natives poison their arrows with its juices, and those have died who have ventured to sleep under its shade. The lobelia longiflora of America produces a suffocating oppression in the breast of those who respire in its vicinity. The return of a periodical disorder has been attributed to the exhalation of the rhus toxicodendron. Every one knows, says Chaptal, the effects of musk and oriental saffron on certain persons. Ingenhousz mentions a young lady whose death was occasioned by the smell of lilies; and Triller reports an instance of another who died in consequence of the smell of violets. The selection of grasses by different animals seems to be owing to the manner in which the volatile aroma affects their senses. But of all the vegetable exhalations known, those emitted by the bohun-upas, or poison-tree of Java, are the most remarkable. For many miles round no animal can breathe the air, no plant dares to peep from the soil, the fishes die in the poisoned stream, and the birds that venture athwart the atmosphere with despairing shrieks sink down lifeless. Such often is the use of the fragrant oils in the vegetable economy. The shrubs and trees that are covered with thorns are in general a grateful food to animals. They generously avow their manner of attack, and scorn the dark assassination by poisons.

The various colours of the integuments, as well as the aroma, is a species of defence. "Caterpillars which feed on leaves (says Darwin) are generally green, and earth-worms the colour of the earth which they inhabit. Butterflies which frequent flowers are coloured like them. Small birds which frequent hedges have greenish backs like the leaves, and light-coloured bellies like the sky, and are hence less visible to the hawk who passes under them or over them. Those birds which are much amongst flowers, as the goldfinch, are furnished with vivid colours. The lark, partridge, hare, are the colour of dry vegetables, or

PHYSIOLOGY.

earth on which they rest; and frogs vary their colour with the mud of the streams which they frequent, and those which live on trees are green. Fishes which are generally suspended in the water, and swallows which are generally suspended in the air, have their backs the colour of the distant ground, and their bellies of the sky." The sphinx-convolvuli, or unicorn moth, resembles in colour the flower on which it rests; and among plants, the nectary and petals of the orphrys, and of some kinds of the delphinium, resemble both in form and colour the insects which plunder them, and thus sometimes escape from their enemies by having the appearance of being pre-occupied. From colour being thus employed as a defence, many animals vary their colours with the seasons and circumstances; and those which are of different colours in summer according to the places which they inhabit, do all in winter assume in common the colour of the snow.

But a change of colour is not the only change of the integuments. As the outermost are often insensible to stimulants, and for obvious reasons possess little of the vital principle; in all cases where they cannot be enlarged to admit an additional increase of growth, or where they are not furnished with necessary organs to repair those injuries which they may suffer from disease or accident, the body is endowed by nature with a power to throw them off, and to produce others in their stead. For this reason we see the tree casting annually its exterior bark, the lobster his shell, the bird his feathers, the quadruped his hair, and sometimes his horns, the serpent his skin, and man himself renewing the scales of the epidermis. These changes usually take place once a year, twice frequently with respect to serpents, and oftener in toads, who have been observed to devour the skin which they throw off. All the integuments of ova and seeds, being wholly the production of parental organs, neither are nor can be repaired.

GENUS VI.—*Nutrition.*

Nutrition is the function which assimilates the food in the several parts, and which finishes the process already begun in the stomach, in the lungs, and the vascular systems. In perfect animals some of the stages of this process are distinctly marked. The chyle, which has some resemblance to milk, is the work of the alimentary canal: it undergoes some new changes by the action of the lacteals, and of their glands when they exist. In the course of circulation it passes along the respiratory organs, and is mixed with oxygen or some other gas: by this mixture, the consequent heat, and the action of the vessels, it is turned into blood. The blood, when examined, spontaneously separates into three parts; an albuminous part or a serum, a coagulable lymph, and red globules. The two first are analogous to the white parts of an egg, by which the chick in ovo is nourished; the globules have some resemblance to the yolk, which serves afterwards as food to the chick in the more advanced period of life. The three parts contain each a variety of principles which are originally composed of gasses: these principles, conveyed through vessels of various forms, of various diameters, and with various degrees of motion and of heat, and all along varying as they pass, arrive at last on the confines of the parts which are wrapt up in a cellular tissue or some other membrane. The tissue or membrane

gives a new change; the parts nourished perform the office of secreting organs; and as the action of the vessels is varied according to the place to which they are tending and the parts which they enter, we see in some degree the manner in which bone, muscle, cartilage, and nerve, are all secreted from a common mass.

In worms and polypes, the function of nutrition is after digestion carried on almost entirely by the cellular tissue; and in plants by a tissue cellular and vesicular. In all living bodies the cellular tissue, besides giving a form to the parts, and besides preventing friction and cohesion, certainly performs some important office. Many have thought it the organ of nutrition; and it surely is one of the organs employed in assisting to assimilate the nutritious fluid. But it should be remembered, that all the parts of the living body are assimilating organs; that each part assimilates for itself; and that the stomach, the respiratory organs, the vessels, and nerves where they exist, are assistant to the whole, and to one another.

It is singular how any should have imagined that the nerves are peculiarly the organs of nutrition, or that growth should be owing to the addition of some organic and vivifying particles pre-existing in the food. These physiologists have not demonstrated the existence of nerves in all living bodies; and these organic and vivifying particles have as yet been discovered but in their fancy. Dr. Mouro has condescended to prove, that the limb of a frog can live and be nourished, and its wounds heal, without any nerves: and Mr. Hunter has given many instances of a living and nutritious power in the blood.

In plants and animals, the assimilating power has always certain limits prescribed to it: its influence is very generally confined to the sort of food congenial to the species; and its strength is varied according to circumstances, as the age, the habits, and the state of health. Those which are young assimilate faster than those which are old; and one species, which may partly be owing to the nature of their food, will assimilate much faster than another. Certain worms that feed on animal and vegetable substances will, in 24 hours after their escape from the egg, become not only double their former size, but will weigh, according to Redi, from 155 to 210 times more than before. Most oils are of very difficult assimilation; and those which are essential will often resist the long continued and the varied action of the living organs; will mingle with the parts, and, undecomposed, communicate their flavour.

An assimilating power is not peculiar to living bodies; it is observed in ferments and contagion, and is so obvious with respect to flame which is neither living nor organized, that whole nations who have seen it feeding on inflammable substances, have been disposed to think it was animated, to call it the principle of life itself, and to pay it a kind of religious homage as the proper emblem of that Being by whom the whole universe is upheld.

In living bodies nutrition is only a species of secretion.

We now pass on to the SECOND ORDER of M. Richerand's FIRST CLASS of functions, and which consist of those that establish his relations to surrounding beings.

GENUS I.—*Sensations.*

Irritability is that property of the living fibre

PHYSIOLOGY.

by which it acts in consequence of stimulants. Being one of the great causes of motion in living bodies, no property has excited more wonder, been the cause of more error, or exhibits such a number of striking phenomena to the senses. These effects, however, have arisen rather from the nature of the stimulants than from any thing mysterious in irritability. Many of the stimulants by which this property in bodies is displayed are often invisible, unknown, or unthought of; and men being conscious that a number of their motions proceed from a stimulant that is under the direction of a mental power, they readily conclude from a sort of analogy, that every motion in plant and insect that seems to answer a useful purpose, and is caused by some invisible stimulant, is the consequence of mind directing from within. They further suppose that irritability is in all cases the consequence of nerves, which are those organs which nature has employed in the animal kingdom to convey stimuli between body and mind. These singular conclusions have led to others that are less admissible even than themselves. It has been imagined that creatures the most stupid possess within them a principle of mind that is incapable of further improvement, but which, notwithstanding, is in many respects superior to reason, and a surer guide in whatever relates to self-preservation or that of the species: it enables the animal to predict without foresight, and to act rationally without intelligence. This wondrous principle has been called instinct: and in order to account for some of the singular phenomena of vegetables, a share of it has graciously been allowed to plants; which having become favourites of late, have been also presented with the privilege of sensation, permitted to fall in love, and to marry, and on some occasions to exercise the faculty of volition.

At these concessions the metaphysician will naturally smile. He knows how many impose on themselves by the mere sound of their own words, as if by calling the snow black they were to discover a new property; which curious discovery would turn out at last to be only a gross ignorance of language, and the foolish misapplication of a syllable. He who has studied the philosophy of mind, and been accustomed to view objects through another medium than the magic colourings of passion and of fancy, readily perceives a something of absurdity in ascribing such wisdom to plants and insects. With respect to animals, these gentlemen do not recollect that voluntary actions are of two kinds, as they proceed from design or propensity; that in performing one of these kinds the mind itself has an object in view, and is properly the source whence they originate; but that in the other the mind is merely a secondary agent, is acting under the influence of stimulants, is often not aware of the consequences, or although aware, is often so infatuated as not to regard them, however fatal. It is generally well known to the naturalist, that not a few of these propensities arise from the form and structure of the body, from the manner in which the optic nerve is affected by colours, the olfactory by smells, the gustatory by tastes, and the auditory by sounds; from the different ways in which the fauces are affected by thirst, the stomach by hunger, and the genital parts by venereal orgasm.

Besides these and other propensities which operate as stimulants in the system itself, the naturalist has found that light, heat, and moisture, in various degrees from absolute darkness, coldness,

and dryness, act as stimulants upon living bodies: he has experienced that electricity is a general agent, that several plants emit flashes, and that some animals even give shocks resembling the electric. He has made it probable that it produces all the wonders of crystallization; and that the cause of chemical affinity, and of all the phenomena displayed by the magnet, if not simply a modification, is at least akin to it. In the male parts of plant and animal, he has seen both the fluid and the pollen that give the stimulus in generation, and are accompanied with so extraordinary changes in the system. He has found that much of the vegetable economy, and even the function of generation itself, as the development of the fecundating powder, and its application to the female organ, is partly carried on by wind, heat, and other such agents. He has reason to conjecture that many general agents in nature are yet unknown. By the help of chemistry, he has found out lately a considerable number which are called gasses, which are of the very highest importance in both the animal and vegetable economy, and which, like the aromas of plants, or the causes of contagion, produce their effects without being visible. It is only, too, of a late date that Galvani of Bologna has excited so much curiosity through Europe, by the discovery of a certain stimulus that resides in the nerves, that passes along electric conductors, and which by a certain application of metals occasions a vivid flash in the eye, convulses the body of a living frog, and rouses the detached limbs into action. The change of colour in the integuments according to different seasons and circumstances, though it answer a rational and useful purpose, proceeds from a cause that does not seem to be very well known. Even many agents which are not invisible, nor yet unknown, exert their influence in a secret manner, so as not to be obvious to the senses. It is generally known that many singular movements of plants are owing to heat, many to light, and several to moisture. The barley-corn is often observed to creep on the ground by means of its awn, which dilates or contracts according to the different degrees of moisture. The wild oat, employed as an hygrometer, moves through the barn, travels through the fields, nor ceases to be changing its situation till its beard fall off, or till it meet with a soil where it conveniently may strike root. Upon a similar principle of motion, the ingenious Edgeworth constructed an automaton which moved through a room which it inhabited. It is easily conceived how these singular effects, arising from causes that are unknown, invisible or unthought of, should give birth to the notions of witchcraft and of instinct, and impress the fancy with an idea of something resembling sensation and volition in the vegetable kingdom. These agents, whether invisible, unknown, or unthought of, directed by regular and uniform laws under the great Author of nature, produce effects that indicate prescience, wisdom, and design, and, causing a transient or permanent propensity in the mental part, frequently controul by resistless sway the finite minds that reside in matter. These minds, in a living body, have generally been found accompanied with some system of nerves; and these nerves happening with equal facility and promptness to convey stimuli from the mind to the body and the body to the mind, the great difficulty has been to determine with respect to others when the action proceeds solely from design, solely from propensity, or

PHYSIOLOGY.

from design and propensity together. The uniform conduct of the brute creation would seem to imply that their mind has little of inventive power; that it generally acts from the impulse of propensity; and that its manners are varied, not in consequence of a change of sentiments, but from the induction of new habits, and the application of new stimulants.

It has been observed, that in all animals the vigour of mind has some relation to the quantity of brain in relation to the nerves that issue from it, which is the judicious distinction of Soemering, and to the perfection of its organization; and that the acuteness of the different senses is generally proportioned to the quantity of nerve bestowed on their organs. Man has a greater proportion of brain than any other animal in proportion to the aggregate amount of its nerves; but many an animal has a much greater proportion of nerve bestowed on different organs of sense. Many animals have therefore acuter senses than man; but man has a greater vigour of mind than any other animal on this globe.

The brain of quadrupeds is somewhat similar to that of man, but proportionally smaller, in regard to its aggregate bulk of nerves, and not perhaps so well organized. Willis has observed, that among animals the structure of the cerebrum is more variable than that of the cerebellum; that the former generally furnishes nerves to the voluntary muscles, and the latter with the medulla oblongata to the involuntary. He has likewise remarked, that the round prominences, commonly called the nates and testes, are large in the quadrupeds which are active and vigorous, and in some measure able to procure their own subsistence at birth; that the tuber annulare is large in the quadrupeds that are distinguished for their sagacity; that wherever the tuber annulare is small, the prominence are large, and wherever it is large the prominences are small. From these observations he has concluded that the tuber annulare is the seat of genius, and the round prominences the seat of what has been called instinct.

The brain of birds is seemingly the reverse of the human brain; the cortical substance is the interior, and the ventricles are situated in the white part on the outside. In the brain of the bird there are no circonvolutions like the intestines, no fornix, corpus callosum, nor corpora striata.

The brain of fishes is in many respects similar in its structure to the brain of birds. It is very small in proportion to their body, and is generally surrounded with an oily matter. In one genus of fishes, the gadus, Dr. Monro found spheroidal bodies between the dura and pia mater, and covering the greater part of the nerves like a coat of mail. The two senses, seeing and hearing, in many fishes are often acute. By laying one ear on the water, and striking the surface at some distance, this element is found to be a better conductor of sound than even the air.

The reptile tribes have very little brain, and like the fishes have no ganglions upon their nerves.

Most insects have no brain at all, but a nervous cord that is full of ganglions, that runs from one extremity to the other, and is denominated the spinal marrow. This knotty cord, however, is not marrow; the insect has nothing resembling a spine; and the situation of the cord in the animal is often not along the back but the breast.

In the silk-worm, and most other insects, this cord is in contact with the alimentary canal; and the first ganglion, which is sometimes called the brain, though not in the head, divides, in order to give a passage to the stomach, and again unites in a second ganglion. Swammerdam found in a species of snail a brain with two lobes, in contact with the stomach, moveable by muscles, and without a fixed place in the body.

The polytypes exhibit no appearance of brain or of nerve, as in other animals. Their skin, however, is observed to be full of a number of small granular bodies, which are connected by a glaucous matter that resembles a thread. Like rows of bead-strings, they extend from one extremity to the other, and along the arms. Trembley learned from a number of experiments that they received their colour from the food, and therefore supposed them to be vesicles or glands. If not like the tuberos nerves of the insects, they at least are not very different in appearance from the nerves of the gadus that are covered with a number of spheroidal bodies like a coat of mail.

Some things would insinuate that a nervous system does not seem to be necessarily connected with mind. The stimuli of nerves may be brought into action by other causes besides mind. Even many nerves are not subjected to the influence of mind; and the mind often by its own inattention may lose the power which it originally possessed over nerves. Many persons can move the muscles of the ear, and others may have lost that power through neglect. After Fontana had observed that the heart was a voluntary muscle in a wheel polype, he learned to retard and accelerate the motions of his own at pleasure. If some nerves, from a sort of prescription, thus cease to be obedient to the power of mind, others by frequent service and habit become so obedient as to convey their stimuli to the muscles almost without the consciousness of mind. The motions excited by the stimuli of nerves are in many cases exceedingly rapid. These may be seen in the wings of most insects, but are most noticed in dancers, tumblers, and apes, and all those animals that are exhibited for feats of agility.

The motions which we see excited in the body by the stimuli of nerves have often been so vigorous and prompt, as to have torn the muscle from the bone, and to have broken the bone itself. They often affect the organs of secretion, have often unhinged the fabric of the system, occasioned death, and accounted for the miracles that have been ascribed to the power of fancy. The prompt motions of what have been named sensitive plants seem owing to a different species of stimulants acting on extremely irritable fibres.

In the animal kingdom, all muscles in the time of action are observed to discharge a quantity of their blood; and those muscles which are naturally white are the most irritable. In all living bodies, the irritable power will cease to obey the action of a stimulant, if either long or violently applied. After exercise, therefore, the irritable fibre requires rest, after heat cold, after waking sleep, before it again becomes submissive to the action of the stimulant that overwhelmed it. This is the reason that in plants and animals there are certain exertions and functions of the system that can only be continued at intervals and seasons. The natural stimuli of involuntary muscles continue to act, and the muscles continue to obey through life. See the article SLEEP.

PHYSIOLOGY.

The organs of sense were formed to mark the difference of stimulants; yet living bodies are affected by light without having eyes, by sounds without having ears, by odorous effluvia without having smell, and by sapid bodies without having taste. It is easily conceived how these objects, by their inherent properties or motion, may produce a confused sort of excitement in every highly irritable fibre. But the organs of sense are peculiarly fitted to receive accurate and distinct impressions from each of these objects; and these different impressions seem not to arise from any difference in the kind of nerves by which they are received. All the difference that has been observed arises from the structure of the organ itself, and from the manner in which the nerve is distributed through it. Other parts of the animal body, as the stomach, the fauces, and the genital organs, are thus affected by particular stimulants; and many animals, and even vegetables, may be affected in various manners, and by various stimulants, of which neither our feelings nor our senses can give intimation of anything analogous.

With respect to the several organs of sense, some animals have many eyes without any motion, and some animals have few eyes with varieties of motion. The entrance to the ear in some animals is from the mouth, as happens in the frog; and the bones of the ear are without the cranium, as in some fishes. The sense of smelling is found in the nose: this sense is astonishing in dogs; and even sheep, in distinguishing their lambs, trust to it more than to seeing or hearing. The sense of taste is far from being general; and the sense of touch resides generally, though more acutely in some organs than others.

GENUS II.—*Motions.*

Irritability is one of the great sources of motion in all living bodies; and this power is brought into action immediately by nerves or some other stimulants. Locomotion here is principally considered; for although the kinds of internal motion employed in secretion and the other functions be as remarkable, in the eye of the philosopher, they have not so generally attracted attention. Most animals are capable by nature of changing the place which their body occupies; for this reason, the irritable fibres, being formed into bundles which are called muscles, are in most animals attached to bones, cartilages, or hard integuments, which they move as levers: these levers, with their muscles attached, are in most cases formed into wings, fins, and legs of various kinds, and are employed in performing the motions of flying, swimming, walking, leaping, and creeping. So very necessary, in the opinion of some of the ancients, was one or other of these instruments to progressive motion, that the movement of the serpent was often ascribed to a preternatural cause, was supposed to resemble the *incessus deorum*, and procured to the animal one of the highest and most honourable ranks among the emblematic kinds of divinities. Notwithstanding, however, the surprise that has been occasioned by its singular movement, the motion of snails, though not so rapid, is in many respects as extraordinary: they adhere by a certain viscid secretion; on dry ground this secretion forms a pavement over which they glide; and they proceed by the action of muscles, without bone, cartilage or shell to which these muscles can be attached.

No animal walks without legs or flies without

wings; but there are many that swim without fins, and that leap and creep without any legs. The rapidity of movement is not proportioned to the number of instruments that are employed: if the spout-fish be observed to move slowly with one leg, the sea-urchin moves still slower with many thousands; the oyster moves by squirting out water; the scallop by the jerk of its shell, and when in the water it rises to the surface and sails before the wind.

Many animals are formed by nature to fly, walk, leap, and swim: the fate of those is rather uncommon whose muscles or feet are by nature attached to their integuments; the lobster is obliged to throw off its shell, and the caterpillar all its feet with the skin, and in that situation to remain stationary till it receive new instruments of motion.

Whoever has read the celebrated work *De Motu Animalium*, needs not to be told that, besides the organs which are here mentioned, the form, the structure, and even the specific gravity of the body, as depending on the nature of the bones and muscles, or as varied by air, vesicles, and bubbles, with a great variety of other circumstances, are necessary to explain the different phenomena of locomotion.

As to vegetable motions, they evidently depend on external agents. The motion of the wild oat has been mentioned; the wings of seeds only fit them to be carried by the wind, their specific gravity to float in the water, and their legs or tentacles to adhere to bodies that are in motion: the singular motions which have been ascribed to sleeping, to waking, to sensation, and volition, in the vegetable kingdom, seem only the consequence of light, heat, moisture, and such stimulants, acting invisibly or with secret influence: the opening and closing of the meteoric flowers are always correspondent to the states of the atmosphere; and the opening and closing of the equinoctial and tropic flowers, to the light, the length, or shortness of the day.

The principal intentions of locomotion are, to get food, to shun danger, to promote intercourse, and disperse the species.

GENUS III.—*Voice and Speech.*

The voice is a sound resulting from the vibrations which the air suffers during its passage through the glottis, when expelled from the lungs. Speech or articulated voice is produced by this sound modified by the motions of the tongue, lips, and other parts of the mouth. It is obvious, therefore, that no animals can have a voice, unless they possess lungs.

The larynx is the instrument of the voice, of which the rima glottidis is the immediate organ. Hence, if the trachea be opened below, so as to prevent the air from passing through, the voice is destroyed; while, if the opening be made above, the speech only is destroyed.

It is universally agreed among physiologists, that the air, expelled from the lungs in expiration, striking against the sides of the rima glottidis (chordæ vocales) constitutes the voice. But it is necessary that the opening should be placed in some condition produced by an exertion of the will; for although air is constantly passing to and fro, the voice is not formed unless by an express effort for that purpose; neither is it formed during sleep; nor after the muscles of the arytenoid cartilages have been paralysed by dividing their nerves.

PHYSIOLOGY.

The manner in which the voice is changed from acute to grave, and *vice versa*, has been much disputed: whether it arise from dilatation and contraction of the aperture, or from tension and relaxation of the chordæ vocales. On the former supposition the human larynx may be compared to a wind instrument, in which the enlargement of the aperture renders the sound grave, and its diminution acute. By the latter explanation it resembles a stringed instrument. After considering the arguments on both sides, we should be inclined to admit the operation of both causes. The change of the voice from acute to grave at the time of puberty, when the larynx undergoes a remarkable development, as well as its acuteness in females, whose glottis is less by one third than that of man, show that the size of the aperture has a great influence. Observing on the other hand that the vocal chords admit of considerable tension and relaxation, we must allow that these variations will render them susceptible of executing, in a given time, vibrations more or less extensive and rapid. And although they are neither dry, stretched, nor isolated, which are necessary conditions to the production of sound in those stringed instruments to which the larynx has been compared, yet they are analogous to vibrating bodies placed at the top of wind instruments, as the reed in hautboys, the mouth-piece in flutes, &c. and equally contribute to the formation and varied inflexions of vocal sound. That all the changes and conditions of the vocal organs, of whatever description, necessary to the production and modification of sounds, are produced by the muscles of the part, is rendered obvious by the elegant experiment, in which the ligature or section of one or both recurrent nerves, or *paria vaga*, either signally impairs, or entirely destroys, the vocal powers of the animal.

The modifications of the voice are also affected by the length of the trachea; hence the larynx is manifestly drawn up in the neck, in the utterance of acute sounds, and as plainly descends when a grave sound is produced. In singing, where these effects take place in a greater degree, the head is thrown back upon the neck in the former case, and brought forwards on the chest in the latter.

The voice is stronger in proportion to the capacity of the thorax; hence it is weaker after meals, when the stomach, distended by food, prevents the descent of the diaphragm, and in consumptive persons, where the capacity of the lungs is diminished by disease. It acquires more force and intensity, and becomes more sonorous, by its reflections in the mouth and nasal canals. Hence it is disagreeably altered when its passage in this direction is stopped by disease, as by polypus, and it is then commonly, but quite erroneously, said that persons speak through the nose.

Whistling, which is common to man with singing-birds, is produced in the latter by their double larynx; but in the former it is effected by a contraction and corrugation of the lips, in imitation of the effect produced by birds.

In singing, the voice runs through the different degrees of the harmonic scale with more or less rapidity, changing from acute to grave, and *vice versa*, with an expression of the intermediate notes. It requires much more exertion than speech. The glottis enlarges and contracts, the larynx is elevated or depressed, the neck elongated or shortened, inspirations are accelerated, prolonged, or retarded; expirations are long, or short, and abrupt. The power of singing is peculiar to man, and forms the great prerogative of his vocal organs. Whistling is

VOL. IX.

common also to birds; which are often taught to pronounce words without any great difficulty. On the other hand parrots are said, in two or three instances, to have been taught, by vast labour, to produce a kind of imitation of singing; but no barbarous tribe has been, hitherto met with, which has not been accustomed to employ singing as the natural expression of their feelings and passions.

Speech is a peculiar modification of the voice, formed during the expulsion of the air from the chest, chiefly by means of the tongue, which is applied to the neighbouring parts, as the palate and teeth, assisted by the various motions of the lips. A voice is common to brutes with man; it exists already in the newly-born child, and has not been entirely wanting in those miserable children who have grown up in a solitary and savage state, or who have been born dumb. Speech results from the enjoyment and cultivation of reason, and is, therefore, like that endowment, a peculiar and distinguishing gift bestowed on man alone. Instinct is sufficient for the purposes of brutes; but man, who does not possess this, or several other assistances, in supporting and defending himself by his own powers, has received the endowments of reason and speech. These have brought him into the social state, which seems to be his natural destination, in which they enable him to utter his ideas and impart his desires to others.

Articulated sounds are represented by letters that express all their power; and it will be readily admitted that man made a great step towards perfection, when he invented these signs, adapted to preserve and transmit his thoughts. Sounds are expressed by the letters called vowels, which are letters produced by the mere passage of the voice through the mouth; requiring only a greater or less aperture of the mouth. Hence these are the first that the child utters. The consonants, which form the most numerous class of the alphabet, serve to connect the vowels, and are formed by a much more artificial process. These are classed into labial, nasal, oral, and lingual, according to the parts more particularly employed in their pronunciation.

Stammering is a corruption of pronunciation arising from various causes. A tongue too large and thick, diminished power over its actions, as in drunkenness, and unusual length of the frenum belong to this class. Yet sometimes the deficiency does not seem organic; at least a person who stammers will pronounce perfectly if he speak slowly; and it may even be entirely overcome by practice and instruction.

Similar causes give rise to lisping. Want of the front teeth will have this effect.

Dumbness may be accidental, or may subsist from birth. In the former case it arises from organic injury, which affects the mechanism of the parts. In dumbness from birth, deafness seems to be always the cause; so that the absence of speech should here rather be called silence. This, at least, is constantly the case according to the observation of Sicard, on the numerous pupils committed to his care. Here there is an absolute ignorance of sounds, and of their representative value in letters of the alphabet. The vocal organs exhibit no marks of deficiency; they are fit, in short, to fulfil the uses for which nature has destined them, but they remain in a state of inaction because the deaf infant is not conscious that he has the means of communicating his thoughts.

Perhaps the mechanism of *ventriloquism* is not yet understood. The following quotation from

B B

PHYSIOLOGY.

Richerand's physiology will be sufficient to give the reader an idea of the subject.

"At first I had conjectured that a great portion of the air expelled by expiration did not pass out by the mouth and nostrils, but was swallowed and carried into the stomach, reflected in some part of the digestive canal, and gave rise to a real echo; but after having attentively observed this curious phenomenon, in Mr. Fitz-James, who represents it in its greatest perfection, I was enabled to convince myself that the name ventriloquism is by no means applicable, since the whole of its mechanism consists in a slow, gradual expiration, drawn in such a way that the artist either makes use of the influence exerted by volition over the muscles of the parietes of the thorax, or that he keeps the epiglottis down by the base of the tongue, the apex of which is not carried beyond the dental arches.

"He always makes a strong inspiration just before this long expiration, and thus conveys a considerable mass of air into the lungs, the exit of which he afterwards manages with such address. Therefore repletion of the stomach greatly incommodes the talent of Mr. Fitz-James, by preventing the diaphragm from descending sufficiently to admit of a dilatation of the thorax, in proportion to the quantity of air that the lungs should receive. By accelerating or retarding the exit of the air, he can imitate different voices, and induce his auditors to a belief that the interlocutors of a dialogue, which is kept up by himself alone, are placed at different distances; and this illusion is the more complete in proportion to the perfection of his peculiar talent. No man possesses, to such a degree as Mr. Fitz-James, the art of deceiving persons who are least liable to delusion: he can carry his execution to five or six different tones, pass rapidly from one to another, as he does when representing an animated dispute in the midst of a popular assembly."

We now advance to the **SECOND CLASS** of Mr. Richerand's division, which consists of functions contributory to the preservation of the species, the **FIRST ORDER** referring to those that require the cooperation of both sexes: upon which we shall only offer a few general observations to what the reader will already find under the articles **ANATOMY, COMPARATIVE ANATOMY, FETUS, and GENERATION.**

The bodies of the male and female present very obvious differences in appearance and character, which have been ascribed to the influence of the generative organs upon the constitution. The removal of the testes in the male prevents those changes in the beard and voice, at the time of puberty, which would otherwise occur: and eunuchs even approach in other respects to the female character, as in the breadth and projection of the hips. Again, in some remarkable cases, where the organs of the female have been wanting, or mal-formed, similar effects have taken place in the constitution; so that there is some reason for saying with Van Helmont, *propter solum uterum mulier est, id quod est.*

Hermaphroditism, or the union of both sexes in the same individual, is impossible in man and the warm-blooded animals. All the supposed hermaphrodites hitherto examined were mal-formed beings, whose male organs were imperfect, or the female apparatus too prominent, so as to render the sex doubtful. No one has shown himself capable of impregnating his own person, so as to produce a being like himself; indeed, in most instances persons thus misconstrued have been in-

capable of assisting in reproduction, the imperfection of the organs employed for this purpose having condemned them to sterility.

Man presents a peculiarity, in not being subject to the influence of the seasons in the exercise of his generative functions; while other animals only cohabit at fixed periods and certain times of the year, and afterwards seem to forget the pleasures of love to satisfy other wants.

Conception. Physiologists have not hitherto succeeded in explaining the mechanism of that elongated and distended state of the penis, occurring under the irritation of the sexual passion, which adapts the organ to the performance of its natural functions. The obvious circumstances are, that the cells of the corpus spongiosum urethræ, and corpora cavernosa penis, are distended to the utmost with blood, poured into them from the arteries much faster than it can be, or at least is returned by the veins. The irritation, which affects the penis, extends to the internal parts. The secretion of the testes becomes more active, and these bodies are drawn up towards the abdomen; the vesiculæ seminales, and the ducts of the prostate, also pour out their contents into the urethra. The semen is a mixed fluid, derived from the three sources just mentioned; but the smallest part probably comes from the testes. The most remarkable circumstance in this fluid is, that it contains numerous microscopic animalcula, with a round head and slender tail, moving about with rapidity.

The prolific liquor is expelled from the penis by a spasmodic action of the accelerator urinæ muscle: the whole body seems to participate in the same convulsive state, and the instant of ejaculation is marked by an orgasm through every part. It seems that nature has forgotten, for the moment, every other function, and is totally occupied in collecting her powers, and directing them towards the same point. Hence an universal languor follows this general convulsion, and hence the old observation, *omne animal post coitum triste.*

The seminal liquor, thus propelled into the generative organs of the female, is supposed to pass through the uterus and fallopian tubes, and to come into actual contact with the ovaria. The closeness of the mouth, and indeed of the whole cavity of the uterus, together with the very small calibre of the fallopian tube, especially at its origin in the uterus, (where it will only admit a bristle) are difficulties in the way of this explanation, which have led to the opinion, that the semen itself does not penetrate into the uterus, but that an exhalation, or *aura seminalis*, comes into contact with the germs, and is sufficient for their fecundation. This is opposed by the experiments of Spallanzani and others, in which the ova of frogs were readily impregnated by contact of the seminal fluid, but were not at all affected by the vapour or aura.

The attachment of the fimbriæ of the tube to the ovarium, which experiment has shown to occur during coition, establishes an uninterrupted canal from the uterus to the ovarium, and prevents the semen from becoming diffused in the abdomen.

The germ of the future being upon the system more generally admitted pre-exists in the ovarium, where it is formed by a peculiar action of the part, in short, by a true secretion. This germ, in its original state, is a small vesicle of fluid, first noticed by De Graaf, whence the term of ovula Graafiana, applied to their appearance in the virgin ovary. Here we do not mean to countenance

PHYSIOLOGY.

those doctrines of evolution which suppose, that generation only develops germs that have existed from the beginning of the world. It is enough to suppose that the ova produced by the elaboration of blood, carried to the ovaria by the spermatic vessels, contain the rudiments of the new beings. But the germs in that state are inert, and require that the seminal spirit should be employed to rouse them from their inactivity. In birds and reptiles the formation of the germ by the female is incontestable; it is not quite so obvious in the class of mammals; but we infer it here from analogy, and also from the experiment of Mr. Hunter, in which the removal of one ovary from a sow diminished in a remarkable degree the number of young produced.

The SECOND ORDER under the SECOND CLASS, relates to those functions which belong exclusively to the female, such as gestation, parturition, and suckling; upon all which we have already observed in the articles referred to under the last order.

Fetal existence is purely vegetative. The fetus receives the fluids brought by the vessels of the mother to the placenta for its growth and nourishment. It may be considered as a new organ, the produce of conception, participating in the general life, but possessing a vitality peculiar to itself, and, to a certain degree, independent of that of the mother. To say that it is asleep is erroneous; for not only are the organs of sense and voluntary motion in a state of perfect repose, but also several of the assimilating functions are totally unemployed, as digestion, respiration, and the generality of the secretions. The fetus, however, performs spontaneous motions, which accoucheurs enumerate among the signs of pregnancy. It is nourished, like every other organ, by appropriating to itself whatever is found in the blood, brought by the vessels of the uterus proper for its purpose; and the interception of this fluid by the ligature, or compression of the umbilical chord, occasions death.

Suckling. The close sympathy between the uterus and breasts is so obvious, as to attract the notice of every observer. Both these organs are developed at the same period of life, and cease together to perform their functions, when the female becomes incapable of contributing towards the continuation of the species. The breasts increase in size during pregnancy, but are never more swelled than after parturition. The infant applies its mouth to the nipple, and sucks; *i. e.* forms a vacuum by inspiring, in consequence of which the atmospheric pressure forces the milk through the lactiferous tubes into its mouth. The nipple experiences a vascular turgescence, or kind of erection; which also affects the excretory tubes of the mammary gland, so as to cause them sometimes to expel the fluid to some distance by jets. The structure of the breast is explained under the article MAMMARY GLAND, and the composition of their secretion under MILK.

The remaining divisions of M. Richerand's classification form what may be regarded as a kind of appendix to it. They comprise the growth of the body, manhood, with its various temperaments, idiosyncrasies and transformations, decay and death.

GENUS I.—Growth of the Body.

The first perceptible traces of the fetus occur about three months after conception. It is then animated by a very slight kind of vegetable life, and possesses true blood, and motion of the heart about the fourth week. The latter, as observed in the chicken, has been named, from the time of

Aristotle, *punctum saliens*. The formation of the bones commences about the seventh or eighth week. The earthy particles are first deposited in nuclei in the clavicles, ribs, vertebrae, larger cylindrical bones of the extremities, lower jaw, and face: a very delicate network is also seen in some of the bones of the cranium.

As a general observation, it may be affirmed, that the growth of the embryo, as well as of the child, both before and after birth, is more rapid in proportion as it is younger.

About the middle of pregnancy, the operation of some vital functions is discerned: the secretion of fat and bile commences. At a more advanced period of utero-gestation, the scalp is covered with a short and delicate hair; the nails are formed; the membrana pupillaris destroyed; the external ear becomes firmer and more elastic; and the testes descend.

Besides the important changes in the whole economy which follow parturition, there are certain alterations in the external habit of the body. The down which covers the face at birth disappears; the rugæ of the skin are obliterated; the anus becomes hidden between the buttocks, which are now gradually formed.

The infant gradually brings into action the faculties of the mind. It perceives and attends to external objects, remembers, desires, &c. It smiles in the second month, and seems to dream at no great length of time after birth. The organs of sense become more complete in their formation. The bones of the skull become stronger, and the fontanels are diminished. Dentition commences about the eighth month. The infant may then be weaned, as his teeth enable him to commence the use of more solid food. About the end of the first year he learns to stand on his feet, and to assume the erect posture, that most distinguishing attribute of the human body.

When it has now been removed from the breast, and learned the use of the lower limbs, its powers and independence increase daily, and receive a vast accession from the development of another peculiar privilege of the human subject, the enjoyment of speech; by which the tongue, under the direction of the mind, pronounces those ideas which are now become familiar.

At the seventh year the twenty milk teeth begin to fall out, and are succeeded in a gradual progress during the following years by the thirty-two permanent teeth. At this time the memory excels all the other faculties of the mind; whereas about the fifteenth year the powers of imagination begin to prevail. This is the time of puberty, in which the human subject is gradually prepared, by various important changes, for the exercise of the sexual functions. The breasts enlarge in the female, the chin becomes covered with hair in the male, and other similar signs of puberty are noticed in both sexes. The menstrual discharge commences in the softer sex; and this important era in the economy of the female is marked by an increased expression in the eyes, and redness of the lips, and more manifest sensible qualities in the matter of perspiration. The seminal secretion becomes active in the male, attended with an increase of the beard, and a deepening of the voice consequent on a remarkable development of the larynx. The internal and spontaneous calls of nature now rouse the sexual instinct, for the exertion of which both sexes are prepared.

No definite and precise period can be assigned for the changes which constitute puberty: it varies ac-

PHYSIOLOGY.

cording to climate and temperament. It is more early in the female than in the male; but in this climate girls may be said to attain it at the age of fourteen or fifteen, and men at seventeen or eighteen. Soon after these periods the growth of the body is completed; the stature of which varies much in different races, not to mention its varieties in individuals and families. The epiphyses, which have hitherto been distinct from the body of the bone, are now completely consolidated with it.

GENUS II.—*Manhood.*

Virility or adult age begins from the twenty-first to the twenty-fifth year. If the increase of the body in height have ceased at this time, it grows in other dimensions. The organs become firm and consistent; their functions are performed with vigour; the intellectual and moral faculties are perfected; and the dominion of the judgment succeeds that of the imagination. This period, which is called that of mature age, extends to the fiftieth or fifty-fifth year in men, but not much beyond the forty-fifth in women, in whom it begins earlier. During this long interval men enjoy all the plenitude of their existence.

Temperaments. As the characters of the human species are now fixed with stability, we may sketch the differences which mark individuals. Health, in the explanation of which all physiology is concerned, consists in such a harmony and equilibrium of the material fabric of the body, and of its animating powers, as is necessary for the performance of the various functions. It requires, therefore, fluids rightly prepared; solids duly formed from these; the latter thoroughly animated by their vital powers; and, lastly, a sound mind in this healthy body. These four principles are constantly acting and re-acting in the human body. The fluids act as stimuli on the solids; which possess vital powers, enabling them to receive those stimuli, and to react. The connection of the mind and body is not discerned merely in the influence of the will, in what physiologists call voluntary actions; since the affections of the body clearly act on the mind in many other ways than through the medium of sensual perceptions. The infinitely varied modifications, which the four principles admit of, show immediately with what latitude our notions concerning health should be formed. Hence arises the distinction of temperaments; that is, the different manner in which the living solid is affected by stimuli, particularly of the mental class, the different aptitude for such impressions, and the greater or less facility with which these stimuli may themselves be excited. There is such great variety of degrees and combinations of temperaments, that a wide field is open for those who wish to employ themselves in dividing and arranging them. The common division is sufficient for our purpose; it comprehends the sanguineous, which is very easily but slightly affected by stimuli; the choleric, which is easily and strongly excited; the melancholic, which is slowly but deeply moved; and the phlegmatic, which is the slowest of all in admitting the impressions of exciting causes. Together with these distinctions, there are numerous differences of bodily formation, of diversity in the proportion and connection of parts, as well as in the energy relative to certain organs, accompanying each temperament, which cannot be particularized here without entering too much into detail.

Each individual has a particular manner of being, which distinguishes his temperament from that of every other, to which, notwithstanding, it

may bear a very strong resemblance. These individual temperaments, the knowledge of which is of no small importance in the practice of physic, are called idiosyncrasies.

There are many both predisposing and occasional causes, which have an operation in producing this diversity of temperaments: as hereditary disposition, climate, diet, religion, culture, luxury, &c. all which may be regarded as so many modifications of habit; and the effect of habit is well known to be so powerful as in many instances to produce a sort of new or secondary nature. Thus at the Cape of Good Hope the ostrich inclines to sit on her eggs day and night like any other bird; but in Senegal, where the heat is greater, she is somehow disposed to leave them to the sun during the day. In those countries where provisions can be found during the greatest part of the year, the bee gradually loses the propensity of laying up stores for the season of winter; and in "those countries infested with monkeys, many birds (says an amusing and instructive writer) which in other climates build in bushes and the clefts of trees, suspend their nests upon slender twigs, and by this ingenious device elude the rapacity of their enemies." Man, from imitation, is exposed to a great number of habits peculiar to himself; and physical causes have ingeniously been assigned for the variety of his features and complexion.

Few experiments have yet been instituted with a view to show how far this accommodating principle in nature may be extended in the different species of plants and animals. It is known, however, that the lamb and the dove can be made carnivorous; and that the hawk, laying aside his ferocity, can be brought by art to live upon grain.

Of all the effects of this singular principle, the most wonderful are those which are seen to take place with respect to generation. The fact is far from being new to the naturalist, that certain animals, oviparous at one season, are viviparous at another. This indicates much of accommodating power, though far inferior to what has been since witnessed and displayed: for who from all this could suspect, that any animal which usually propagates by an intercourse of sexes, could in any circumstance accommodate so far as to multiply its species another way? Bonnet of Geneva, however, has discovered, that the puceron or vine-freter, which generally propagates by an intercourse of sexes, is not only oviparous at one period and viviparous at another, but, in all cases where the union of the sexes is not to be obtained, can easily accomplish all the purposes of generation without it. Similar experiments have likewise proved, that many plants can bring to maturity a productive seed, though the male parts of the flower be destroyed before they can in the usual way have any impregnating effect on the female. In this case, the conclusions drawn have been somewhat new. From these experiments it has been inferred, that the sexual system is ill-founded, and that most of the learned naturalists of Europe are on this subject labouring at present under a mistake. This reasoning, however, is not satisfactory: for why, it might be asked, in the vegetable kingdom more than in the animal, should the mode of generation be necessarily uniform? Though some plants may, like some animals, propagate without sexual distinctions, the conclusion is not logical that these distinctions are useless in all; and though some few may, in particular instances, propagate without that impregnation to which they were ac-

PHYSIOLOGY.

customed, will any one demonstrate, that accommodating nature does not here as in the puceron adopt a new method to accomplish her designs?

In all living bodies, it frequently happens that several characteristic distinctions, as the colour, the features, and a number of diseases that are originally the effects of circumstance, do at last become so fixed in the system, that they are afterwards transmitted to posterity through some generations. With regard to animals these facts are well known; and as to vegetables, it has been observed by a pupil of Linnæus, that the apple-trees which are sent from Britain to New England blossom at first too early for the climate, and bear no fruit; and that it is only after some years that they conform to their situation: and this circumstance, by the way, explains why roots and seeds germinate sooner when brought from southern than when they are brought from northern latitudes. The very permanency of these effects has often been the cause of much confusion and error in philosophy: for the naturalist, mistaking the lasting though temporary qualities of habit for the real and essential qualities of species, has not unfrequently drawn conclusions from his experiments that have been contradicted by similar experiments in other circumstances. This is one of the obvious reasons why experiments exhibit so many inconsistencies and contradictions, and why we are amused with such a multitude of visionary theories about the properties of living bodies.

From not attending to the numerous circumstances that induce habits, and to that general accommodating principle in living bodies, many medical prescriptions are found to be not only useless but mischievous; and many parents, by studying the health and comfort of their children, bring on habits that prove the sources of perpetual sickness, or the certain presages of an early death.

The accommodating principle is one of the consequences of irritability. Its various effects arise from the actions of different stimulants on the irritable fibre; and the after-duration of these effects, from the modifications of the irritable fibre, become habitual from the frequently repeated action of the stimulants.

The design of this accommodating principle is to fit both the plant and the animal for a more extensive and a more varied range of existence.

More remarkably striking however than any of those changes to which the plant and animal are exposed, from the variations of habit or the change of integuments, are those alterations which they undergo from metamorphosis or transformation. It has indeed been asserted, that these alterations consist in throwing off certain temporary coverings or envelopes: but there is here a want of precision in the ideas, and consequently a want of accuracy in the expression. The same persons who make this assertion inform us, that caterpillars change their skin, and many of them even several times, previous to the period of their transformation. Transformation, therefore, and a change of integuments by their own concessions, are different things. The truth is, transformation frequently takes place independent of any change of integuments; and there is often a change of the integuments without transformation or any appearance of a new form: but a new form or change of appearance is always implied in metamorphosis or transformation. This new form is sometimes occasioned by a change of shape, consistency, and colour; as when the lobes of a seed are converted into seminal leaves. It is sometimes occasioned

by a change of proportions among the parts: the proportions of a fœtus, every one sees, are different from those of a full grown man; and the painter, merely by observing the proportions, represents a child, a dwarf, and a giant, on the same scale. It is sometimes occasioned by the addition of new organs; as when the emmet receives wings, and the plume of the seed is fed by new roots striking into the ground; or it is occasioned by a change of both the form and the organs, and their mode of operation, as happens remarkably in some insects: for, though all living bodies, plants and animals without exception, undergo partial or general transformations, yet these changes are chiefly observable among insects. Many insects appear to consist of two distinct animal bodies one within the other: the exterior, a creature of an ugly form, residing in the water or under the earth, breathing by gills or sometimes by tracheæ projecting from the tail, possessing a voracious and grovelling appetite, and having a system of sanguiferous vessels that circulates the blood towards the head. When all its parts decay and fall off, the creature inclosed succeeds in its stead: this often is an animal of a different form, generally lives in a different element, feeds on a different species of food, has different instruments of motion, different organs of sense, different organs of respiration, and differently situated; and, being endowed with the parts of generation, inclines to gratify the sexual propensity, and produces an embryo which becomes like the first, and from which afterwards in process of time a creature is evolved similar to itself.

If the embryo or egg be deposited on a leaf, the leaf frequently is observed to bend, to wrap it in folds intended for the purpose, and to protect it from injuries and danger. If deposited in the body of an animal or plant, they accommodate themselves to its wants and necessities, and furnish a tumour which serves it for a nidus, and besides, like an uterus, supplies it with nourishment; and if deposited in the body of an insect, the creature provides for the future destination of its young charge with all the tender care of a parent, and then dies.

These circumstances, added to the great variety of forms which insects assume, render it sometimes difficult to know who is the parent. We cannot, for instance, pronounce with certainty who is the true parent of the gordius, known by the name of the *seta equina*, or hair eel. A set of experiments, which we once began with a view to throw some light on the subject, were interrupted unfortunately by an accident, and we have not since had leisure to resume them. We learned only, from a number of observations, that certain black beetles about the end of the summer months have the strongest propensity to run into the water, where they soon die; and that one or two, and sometimes three or more, of those eels gradually drop from the beetle by the anus. Whether other insects provide for the gordius in this manner we have not yet been able to determine.

The transmutations of some animals are most observable in the uterus and egg: and anatomy has often witnessed the change which happens at birth with respect to circulation, respiration, digestion, and the other functions.

If the reader wish to be much acquainted with the manners and transformations of insects, he will derive information and pleasure from consulting the plates and memoirs of Reaumur. If he wish to know their intimate structure, the laborious Swammerdam can introduce him to a new and amusing species of anatomy. This last author had

PHYSIOLOGY.

before Reaumur defined and described the kinds of transmutations among insects and some other animals. He was shown similar transmutations in plants; and in plate 46 of his Book of Nature has compared the frog and the clove July-flower under their six different forms.

In all living bodies possessed of mind, the changes of form, as well as the change of habit and of age, are usually accompanied with new propensities, appetites, and passions. It may therefore be inferred, that we ought not to look for the cause of temper in either the brain or the nervous system; or to imagine, that the propensities, appetites, and passions, are properties of mind: they seem only affections happening to mind in consequence of stimuli and organic structure.

Microscopic observations having demonstrated, that all the forms of the plant and animal existed previously in the seed or embryo, transformation must be owing entirely to the evolution of the different parts by means of nutrition.

What nature intends by transformation, we pretend not to say; but by means of transformation different elements are peopled, the different seasons variously adorned, and animated nature wonderfully diversified without a multiplication of beings. For the various races of mankind, see the articles MAN and HOMO.

GENUS III.—Decay and Death.

Death is the cessation and total absence of the living principle in organized bodies. It is sometimes imitated by sleep and swoons; and a state of torpor in many instances can hardly be distinguished from it. Several mosses and a few animals, as the ears of blighted wheat, the seta equina, the wheel polype, and some snails as we learn from the Philosophical Transactions, may be safely preserved as dried preparations, not for months only but for years; and after irritability and sensation have been totally suspended, will return to life upon the proper application of moisture. A wheel polype was put by Fontana upon a bit of glass, and exposed during the whole summer to the noonday sun; another was exposed in a similar manner for a year and a half; and, after they were like a piece of hardened glue, were restored to the use of all their functions by a few drops of water. Wherever there is death, there must therefore be likewise a partial or general decomposition of one or more of the vital organs. This decomposition takes place naturally in some living bodies after a few hours, in some after a few days; the life of others is extended to weeks; some are vigorous for months or a season. Man has often seen more than four-score; and the hardy oak survives the shock of two or three centuries. These observations conspire to show that there is a certain period of existence allotted by nature to every species of living bodies. In the individual this period is sometimes abridged, and may be sometimes extended by circumstances; but yet there is a bound which it cannot pass, when the vital organs must be decomposed, and the system return to moulder with the dust. The time of incubation and the time of gestation are pretty much defined in every species, because the circumstances of the individual in these cases are generally similar; but, after emerging from the foetal state, the individuals are partly entrusted to their own organs and the chances of life, which are much varied; and hence we account for the difference of their age.

Life in general seems to be proportioned to the space occupied by that series of functions which the species is evidently destined to perform: and

here sometimes the accommodating principle is singularly remarkable. As the period of decay is never seen to commence in the species till that of propagation be nearly elapsed, and as propagation in the lower tribes of plants and of animals is often the immediate harbinger of death; so many animals which have not propagated, indulged the propensity, nor become uneasy from the languor of desire, continue vigorous longer than ordinary, as as if it were waiting for an opportunity to multiply their kind. And in the vegetable kingdom, where no individual is ever the victim of desire or passion, annuals, if prevented from flowering and seeding in their proper season, will live double, and sometimes triple, the usual time, till these functions be somehow performed, and then die. But when all the organs are fully evolved and have discharged, or have continued for the usual time capable of discharging, those offices for which they were intended; dissolution commences, the assimilating organs begin gradually to lose their tone, and the re-absorbents carry off more from the different parts than what they receive in the way of nutrition: the irritable fibre then becomes rigid; the membranes and cartilages begin to ossify; the bones grow harder; the smaller vessels collapse and disappear; the parts no longer are obedient, as before, to the action of stimulants; and death ensues.

Some, in order to account for this event, imagine that the body receives at first a certain portion of irritability, and continues to live till that be exhausted: but this theory explains nothing; and without pretending to a great deal of foresight, we will venture to predict, that for all the irritability which it has, it will not be distinguished for its longevity.

With regard to the periods by which the life, the functions, and diseases of living bodies are so frequently regulated, and which periods may sometimes be varied but not evaded, the most prudent language that, perhaps, can be adopted in the present state of physiological science is this of the Divine, That the God who formed us hath numbered our days, determined our times, and prescribed the limits of our existence.

PHYSOCELE. (*physocèle*, φυσοκηλη; from *φύσα*, wind, and *κηλη*, a tumor.) Any species of hernia, whose contents are distended with wind.

PHYSOCEPHALUS. (*physocephalus*, φυσοκεφαλος; from *φύσα*, wind, and *κεφαλη*, the head.) Emphysema of the head. See **PNEUMATOSIS**.

PHYSOMETRA. (*physometra*, φυσομετρα; from *φύσσω*, to inflate, and *μετρα*, the womb.) A windy swelling of the uterus. A genus of disease in the class cachexiæ, and order intumescentiæ, of Cullen; characterized by a permanent elastic swelling of the hypogastrium, from flatulent distention of the womb.

PHYSOPHORA. In zoology, a genus of the class vermes, order mollusca. Body gelatinous, pendent from an aerial vesicle, with gelatinous, sessile members at the sides, and numerous tentacles beneath. Three species, oval-orbicular or filiform. The orbicular, *P. rosacea*, an inch in diameter, and resembling a full-blown flower bending downward. The filiform, *P. filiformis*, a span long, not thicker than a thread, with an obtuse ovate head about the size of a grain of rice. They all inhabit the Mediterranean Sea, and are nearly allied to the medusæ,

Phytoliths.

*Fossil Plants in whole
or in parts.*

*Specimens of
Opaline & Sasperine
Wood.*

Phytoliths.

Fossil Plants in whole or in part.

Specimens of the Leaves and Stalks of Plants preserved in Fossil Bodies.

Phytolithi.
Fossil Plants in whole
or in parts.

Specimens of Bituminous and Aggrine Wood?

to which genus they might be removed without impropriety.

PHY'SY. *s.* The same with *fusee* (Locke).

PHYTEUMA. *Rampion.* In botany, a genus of the class pentandria, order monogynia. Corol wheel-shaped, five-parted, with linear segments; stigma two or three cleft; capsule two or three celled, inferior, opening laterally. Sixteen species, chiefly natives of the Alps, and warmer parts of Europe; one, *P. orbiculare*, indigenous to our own country, and found wild on the downs of Sussex. Of these some have their flowers in spiked heads, others axillary and scattered.

PHYTIVOROUS. *a.* (*φυτο* and *voros*, Lat.)

That eats grass or any vegetable (*Ray*).

PHYTOGRAPHY. *s.* (*φυτο* and *γραφω*.)

A description of plants.

PHYTOLACCA. *American nightshade.*

In botany, a genus of the class decandria, order decagynia. Calyxless; petals five, resembling a calyx; berry superior, ten-celled, ten-seeded. Six species, natives of Abyssinia, North and South America; one of Switzerland. The following are cultivated,

1. *P. octandra.* White-flowered phytolacca.
2. *P. decandra.* Branching phytolacca.
3. *P. icosandra.* Red phytolacca.
4. *P. dioica.* Tree phytolacca.

In Virginia and other parts of America the inhabitants boil the leaves of *P. decandra*, and eat them in the manner of spinach. They are said to have an anodyne quality, and the juice of the root is violently cathartic. The Portuguese had formerly a trick of mixing the juice of the berries with their red wines, in order to give them a deeper colour; but it was found to debase the flavour. This was represented to his Portuguese majesty, who ordered all the stems to be cut down yearly before they produced flowers, thereby to prevent any farther adulteration.

They afford ornament and variety among potted plants of the stove kind; and *P. decandra* in the borders of the natural ground.

PHYTOLITHUS, in oryctology, a genus of the class petrifications, order vegetable: consisting of a vegetable or some parts of it changed into a fossile substance. Six species:

1. *P. totalis.* The whole plant. The varieties are very numerous: and consist of marshall, iris, sage, various grasses, chervil, fennel, heath, euphorbia, cactus, anemone, geranium, fumitory, vetch, birds-foot, goats-rue, box, milfoil, pine, ferns of numerous kinds. These are found in various parts of Great Britain, France, Germany, Italy, Bohemia, Saxony, and most parts of Europe, generally in schistose and bituminous marl and alumine covering veins of coal, sandstone and other fossils; almost always in the form of impressions. The best impressions of grasses are found in Switzerland, Bohemia, Silesia and other parts of Germany, in schistose swinestone and alumine lying over beds of coal, rarely in flint.

2. *P. phizolithus.* The roots of vegetables, most commonly found under ground in a state of decay, sometimes hollow or filled with

other fossile substances, sometimes covered with a stony crust; sometimes petrified: found in France, Italy, Hungary, Bohemia, Sweden, Siberia, Germany.

3. *P. trunci.* The trunk or stalk of vegetables. The varieties of this species are very numerous; consisting of the stalk of herbs, the culm of grasses; the trunks of trees, often denominated lythoxylon.

This third species is found still more generally than either of the preceding; for without much attention it may be met with in almost every part of the globe, and in various states of decay and appearance; sometimes forming subterraneous woods, the pieces of which are sound or carious, or perforated by the teredo, converted into charcoal, with or without the bark, and often so perfect as to distinguish the kind, as oak, ash, fir, &c.

The different specimens are found in marmoreous and often filled with spar; in swinestone, gypsum, alumine, silex, agate, opal, sandstone, combined with sulphat of iron, or copper, or with oxyd of iron or copper; pyritaceous, and bituminous; in the last form frequently constituting entire subterraneous woods in various parts of England and Ireland, particularly in Lincolnshire; in Russia, Sweden, Denmark, France, Spain, Holland, Flanders, Germany, Prussia, in strata superincumbent on amber; in Saxony, Bohemia, Austria, Italy, and Switzerland.

4. *P. lithophilum.* The leaves of plants. Impressions of the leaves of various herbs and trees very frequent in marble, schist, marl, clay and sandstone, rarely in flint, or indurated oxyd of iron.

5. *P. antholithus.* The flowers of plants. Consisting

a. Of the spikes of grasses, as the phalaris bulbosa, spica frumenti, &c. found in Silesia, Franconia, and Germany, in copper ores, with often a small admixture of silver.

b. The flowers of herbs, as the galium, heliotropium, alsines, ranunculus, myagrum, aster, centaurea, and various ferns. In England, Silesia, Germany, Switzerland, &c. the impressions appearing between various slabby stones.

6. *P. carpolithus.* The naked seeds, seed-vessels, cones, nuts, drupes, and legumes of plants. Found in the coal-mines of England; in sandstone in Piedmont; in Bohemia in marl; in Switzerland in turf; in Hungary, Austria, &c. always in the form of impressions. See Nat. Hist. Pl. CVIII. CXIII. and CXV.

PHYTOLOGY. (*phytologia*, *φυτολογία*; from *φυτο*, an herb, and *λογος*, a discourse.) That part of natural history which treats on plants. See BOTANY.

PHYTOTOMA. In zoology, a genus of the class aves, order passerres. Bill conic, straight, serrate; nostrils oval; tongue short, obtuse; feet four-toed. One species only: *P. rara.* Bill thick, half an inch long, toothed on each side like a saw; irids brown; body above dusky-ash, beneath paler;

quill and tail-feathers spotted with black; tail rounded; hind toe shorter than the foreones. Inhabits Chili; nearly the size of a quail; has a harsh interrupted cry of *Ra, ra*, whence its specific name: feeds on fresh vegetables, which it cuts down near the roots with its bill as with a saw; and is, on this account, a pest to gardens, and detested by the natives; builds in high, shady trees, in retired places; eggs white spotted with red.

PIA-MATER. (*pia mater*, the natural mother; so called because it embraces the brain as a good mother folds her child.) A thin membrane almost wholly vascular, that is firmly accreted to the convolutions of the cerebrum, cerebellum, medulla oblongata, and medulla spinalis. Its use appears to be, to distribute the vessels to, and contain the substance of, the cerebrum.

PIACLE. *s.* (*piaculum*, Latin.) An enormous crime: not used (*Howell*).

PIACULAR. **PIA'CULOUS.** *a.* (*piacularis*, from *piaculum*, Latin.) 1. Expiatory; having the power to atone. 2. Such as requires expiation (*Brown*). 3. Criminal; atrociously bad (*Glanville*).

PIADELLA, a town of Italy, in the duchy of Milan, 20 miles N. of Como. Lon. 9. 10 E. Lat. 46. 5 N.

PIAFFEUR, in the manage, a kind of movement in a proud and stately horse, that, being full of mettle, wishes to go forward; this excessive eagerness makes his motion the greater as you endeavour to keep him in, and bends his leg up to his belly: he snorts, traverses if he can, and by his fiery action shews his restlessness, whence some, though very improperly, say, he dances. Such horses as these, or such as are bred to passage upon a straight line, are much admired in processions and magnificent festivals.

PIANISSIMO. (Ital.) Very soft. The superlative of *Piano*.

PIANO. (Ital.) Soft. A word used adverbially in opposition to *forte*, loud or strong.

PIANO-PIANO, or **PIU PIANO.** (Ital.) More soft, or very soft.

PIANO-FORTE. (Ital.) A very pleasing stringed and keyed instrument of English origin, being invented by Mr. William Mason, the well-known author of *Caractacus* and other poems; it received its name from its varied command within certain limits, both of softness and strength. The chief beauty of this instrument, and which, indeed, constitutes its principal advantage over the harpsichord, is its capacity of obeying the touch, so as to enable the performer to vary and accommodate the expression to all those delicacies, energies, and striking lights and shades which so greatly characterise the more refined compositions of the present day. The Piano-forte, though of recent invention, has received from the hands both of Englishmen and foreigners many useful and valuable improvements; and in that state in which it assumes the name of Grand Piano-forte, and is furnished with its additional keys, is not only qualified to give brilliancy of

effect to sonatas, concertos, and all pieces of extraordinary execution, but forms an expressive accompaniment to the voice, and is one of the noblest and most elegant instruments in the whole compass of musical practice.

PIANOZA, an island of Italy, off the coast of Tuscany, six miles S. of that of Elba. It is level and low, as the name imports. Lon. 10. 34 E. Lat. 42. 46 N.

PIARA, a river which rises in the mountains of Tyrol, and falls into the gulf of Venice, by two mouths, a little N. of Venice.

PIASTER, or **PIASTRE**, a Spanish money, more usually called a *piece of eight*, in value about 4s. 6d. English.

PIAZZA, in building, popularly called *piache*, an Italian name for a portico, or covered walk, supported by arches. The word literally signifies a broad open place or square; whence it also became applied to the walks or porticoes around them.

PIAZZA, a town of Naples, in Principato Citeriore, 13 miles E.N.E. of Salerno.

PIAZZA, a town of Sicily, in Val di Noto. It contains 18,000 inhabitants, and is situate almost in the centre of the island, 15 miles N.W. of Calata Girona.

PIAZZI, the name by which some astronomers designate the planet discovered by M. Piazzi, of Palermo; and of which we have already spoken under the words **ASTRONOMY** and **CERES FERDINANDEA**. Nothing of importance respecting this planet has been discovered since those articles were put to press.

PIB-CORN, or **HORNPIPE**. The name given by the Welsh to a wind instrument, consisting of a wooden pipe with holes at the sides, and a horn at each end, the one to collect the wind blown into it by the mouth, and the other to convey the sound as modulated by the performer. This instrument is so common in Wales, that the shepherds' boys amuse themselves with it while tending their flocks.

PIBROCH, a species of tune peculiar to the Highlands and Western Isles of Scotland. It is performed on a bagpipe, and differs totally from all other music. Its rhythm is so irregular, and its notes, especially in the quick movement, so mixed and huddled together, that a stranger finds it almost impossible to reconcile his ear to it, so as to perceive its modulation. Some of these pibrochs, being intended to represent a battle, begin with a grave motion resembling a march, then gradually quicken into the onset; run off with noisy confusion and turbulent rapidity, to imitate the conflict and pursuit; then swell into a few flourishes of triumphant joy; and perhaps close with the wild and slow wailings of a funeral procession.

PICA, in ornithology. See **CORVUS**.

PICA MARINA, in ornithology. See the articles **HÆMATOPUS** and **ALCA**.

PICA. (*pica*, so named because it is said the magpie is subject to this affection.) Depraved appetite, with strong desire for unnatural food. It is very common to pregnant women.

PICA, or **PYE**, had formerly the same sense as ordinal, meaning a table or directory, point-

ing out the order in which the devotional services appointed for different occasions were to be performed. Accordingly we are told it is derived from *πιτ*, a contraction of *πιναξ*, a table; and by others from *litera picata*, a great black letter at the beginning of some new order in the prayer. The term was used in a similar sense by officers of civil courts, who called their kalendars or alphabetical catalogues, directing to the names and things contained in the rolls and records of their courts, the *pyes*.

PICA, in printing, a particular size of types or letters, larger than long primer. See PRINTING.

PICÆ. In zoology, the second order in the Linnæan class aves; thus ordinarily characterized. Bill sharp-edged, convex above; legs short, strong; feet formed for walking, perching, or climbing; body roughish, impure; food various filthy substances; nest, in trees; the male feeds the female while she is sitting. They live in pairs: twenty-six genera; for which see ZOOLOGY. See also the article ORNITHOLOGY.

PICARD (John), an able mathematician of France, and one of the most learned astronomers of the 17th century, was born at Fleche, and became priest and prior of Rillie in Anjou. Coming afterwards to Paris, his superior talents for mathematics and astronomy soon made him known and respected. In 1666 he was appointed astronomer in the Academy of Sciences: and five years after, he was sent, by order of the king, to the castle of Uraniburg, built by Tycho Brahe in Denmark, to make astronomical observations there; and from thence he brought the original manuscripts, written by Tycho Brahe; which are the more valuable, as they differ in many places from the printed copies, and contain a book more than has yet appeared. These discoveries were followed by many others, particularly in astronomy. He was one of the first who applied the telescope to astronomical quadrants: he first executed the work called *La Connoissance des Temps*, which he calculated from 1679 to 1683 inclusively: he first observed the light in the vacuum of the barometer, or the mercurial phosphorus: he also first of any went through several parts of France, to measure the degrees of the French meridian, and first gave a chart of the country, which the Cassinis afterwards carried to a great degree of perfection. He died in 1682 or 1683, leaving a name dear to his friends and respectable to his contemporaries and to posterity. His works are, 1. A treatise on Levelling. 2. Practical Dialling by calculation. 3. Fragments of Dioptrics. 4. Experiments on Running Water. 5. Of Measurements. 6. Mensuration of Fluids and Solids. 7. Abridgment of the Measure of the Earth. 8. Journey to Uraniburg, or Astronomical Observations made in Denmark. 9. Astronomical Observations made in divers parts of France. 10. *La Connoissance des Temps*, from 1679 to 1683.

All these, and some other of his works, which are much esteemed, are given in the

6th and 7th volumes of the *Memoirs of the Academy of Sciences*.

PICARDY, a late province of France, bounded on the N. by Hainault, Artois, and the straits of Dover, on the E. by Champagne, on the S. by the isle of France, and on the W. by Normandy and the English Channel. It now forms the department of Somme.

PICART (Bernard), an excellent engraver, born at Paris in 1673. He was deemed the most ingenious artist of his day: numerous proofs of his invention and elegance of exertion are to be seen in a multitude of books he adorned. He died in 1733.

PICARO'ON. *s.* (from *picare*, Italian.) A robber; a plunderer (*Temple*).

PIC'PAGE. *s.* (*piccagium*, low Lat.) Money paid at fairs for breaking ground for booths.

PICCOLOMINI (Alexander), archbishop of Patras, and co-adjutor of Sienna, where he was born in 1503. He wrote several dramatic pieces which laid the foundation of his celebrity; all his works are in Italian, and he is the first author who applied that language to philosophical subjects. He died at his native place in 1578.

PICCOLOMINI (Francis), a learned Italian of the same family as the former. He wrote Commentaries on Aristotle; and died at Sienna in 1604. He was so respected that the whole city wore mourning on the occasion of his death.

PICENI, the inhabitants of Picenum, called also Picentes. They received their name from *picus*, a bird by whose auspices they had settled in that part of Italy.

PICENTINI, a people of Italy near Lucania, different from the Piceni or Picentes, who inhabited Picenum.

PICENUM, or PICENUS AGER, a country of Italy near the Umbrians and Sabines.

PICEA. (*picca*, *πικρος*, pitch.) The common or red fir or pitch tree is so termed. The cones, branches, and every part of the tree, affords the common resin called frankincense. See *TEREBINTHINA VULGARIS*.

PICHARIM. See PECHURIM.

To PICK. *v. a.* (*picken*, Dutch.) 1. To cull; to choose; to select; to glean (*Shak.*). 2. To take up; to gather; to find industriously (*Bacon*). 3. To separate from any thing useless or noxious, by gleaning out either part (*Bacon*). 4. To clean, by gathering off gradually any thing adhering (*More*). 5. (*piquer*, Fr.) To pierce; to strike with a sharp instrument (*Wiseman*). 6. To strike with the bill or beak; to peck. 7. (*picare*, Italian.) To rob (*Shakspeare*). 8. To open a lock by a pointed instrument (*Denham*). 9. To PICK a hole in one's coat. A proverbial expression for finding fault with another.

To PICK. *v. n.* 1. To eat slowly and by small morsels (*Dryden*). 2. To do any thing nicely and leisurely (*Dryden*).

PICK. *s.* (*pique*, Fr.) A sharp-pointed iron tool (*Woodward*).

PICKAPACK. *ad.* (from *pack*.) In manner of a pack (*L'Estrange*).

PICKAXE. *s.* (*pick* and *axe*.) An axe not

made to cut but pierce; an axe with a sharp point (*Milton*).

PICKBACK. *a.* On the back (*Hudibras*).

PICKED. *a.* (*piqué*, Fr.) Sharp; smart.

To PICKER. *v. a.* (*piccare*, Italian.) 1.

To pirate; to pillage; to rob (*Ainsworth*). 2.

To make a flying skirmish (*Hudibras*).

PICKER. *s.* (from *pick*.) 1. One who picks or culls (*Mortimer*). 2. A pickaxe; an instrument to pick with.

PICKER, or HORSE-PICKER, an iron instrument five or six inches long, bent or crooked on one side, and flat and pointed on the other, used by grooms to cleanse the inside of the horse's feet, and pick out the earth and sand that has got in between the shoe.

PICKEREL, a small pike.

PICKERING, a town in the N. riding of Yorkshire, with a market on Monday. It has an old castle, in the ruins of which is kept a court for the hearing of all causes under 40 shillings, in the district called the Honour or Liberty of Pickering. It is 26 miles N.E. of York, and 223 N. by W. of London. Lon. O. 38 W. Lat. 54. 15 N.

PICKET, PICKQUET, or PIQUET, in fortification, a painted staff shod with iron; used in marking out the angles and principal parts of a fortification, when the engineer is tracing out a plan upon the ground. There are also larger pickets, or painted stakes, which are driven into the earth to hold together fascines or faggots, in any work cast up in haste. Pickets are likewise the stakes driven into the ground near the tents of the horsemen in a camp, to tie their horses to; and before the tents of the foot, where they rest their muskets or picks about them in a ring. The same name is also given to the stakes with notches towards the top, to which are fastened the cordages of tents: thus to plant the picket is to encamp. When a horseman has committed any considerable offence, he is sometimes sentenced to stand upon the picket, which is to have one hand and the opposite foot tied together, and being drawn up from the ground by the other hand, he is obliged to stand with one foot on the point of a picket or stake, so that he can neither stand nor hang without great pain, nor ease himself by changing feet.

PICKLE. *s.* (*pekel*, Dutch.) 1. Any kind of salt liquor, in which flesh or other substance is preserved (*Addison*). 2. Thing kept in pickle. 3. Condition; state; ludicrously (*Sh.*).

PICKLE, or PIGHTEL. *s.* A small parcel of land enclosed with a hedge, which in some countries is called a *plingle* (*Phillips*).

To PICKLE. *v. a.* (from the noun.) 1. To preserve in pickle (*Dryden*). 2. To season or imbue highly with any thing bad.

PICKLEHERRING. *s.* (*pickle* and *her-ring*.) A jack-pudding; a merry-andrew; a zany; a buffoon (*Addison*).

PICKLOCK. *s.* (*pick* and *lock*.) 1. An instrument by which locks are opened without the key (*Brown*). 2. The person who picks locks.

PICKPOCKET. PICKPURSE. *s.* (*pick* and

pocket, or *purse*.) A thief who steals, by putting his hand privately into the pocket or purse (*Bentley*, *Swift*).

PICKTHANK. *s.* (*pick* and *thank*.) An officious fellow, who does what he is not desired; a whispering parasite (*South*).

PICKTOOTH. *s.* (*pick* and *tooth*.) An instrument by which the teeth are cleaned.

PICO, the largest and most populous of the Azores, or Western Islands. It has a volcanic mountain, called Pico, which frequently throws out flames, smoke and ashes. The island is about 50 miles in circumference, and produces a great deal of wine. Lon. 28. 21 W. Lat. 38. 29 N.

PICQUET, a celebrated game at cards played between two persons, with only thirty-two cards; all the deuces, threes, fours, fives, and sixes being set aside.

In playing at this game twelve cards are dealt to each, and the rest laid on the table: when if one of the gamblers find he has not a court card in his hand, he is to declare that he has *carte blanche*, and tell how many cards he will lay out, and desire the other to discard, that he may shew his game, and satisfy his antagonist, that the *carte blanche* is real; for which he reckons ten. And here the eldest hand may take in three, four or five, discarding as many of his own for them, after which the other may take in all the remainder if he pleases. After discarding, the eldest hand examines what suit he has most cards of; and, reckoning how many points he has in that suit, if the other has not so many in that, or any other suit, he reckons one for every ten in that suit, and he who thus reckons most is said to win the point. It is to be observed, that in thus reckoning the cards, every card goes for the number it bears; as a ten for ten; only all court cards go for ten, and the ace for eleven, and the usual game is one hundred up. The point being over, each examines what sequences he has of the same suit, *viz.* how many tierces, or sequences of three cards; quartes, or sequences of four cards; quintes, or sequences of five cards, &c. he has. These several sequences are distinguished in dignity by the cards they begin from: thus ace, king, and queen, are stiled tierce major; king, queen, and knave, tierce to a king; knave, ten, nine, tierce to a knave; and the best tierce, quarte, or quinte prevails, so as to make all the others in that hand good, and to destroy all those in the other hand. In like manner a quarte in one hand sets aside a tierce in the other.

The sequences over, the antagonists proceed to examine how many aces, kings, queens, knaves, and tens each holds; reckoning for every three of any sort, three; but here, too, as in sequences, he that with the same number of threes or fours has one that is higher than any the other has, makes his own good, and sets aside all his adversary's; but four of any sort, which is called a quatorze, because fourteen are reckoned for it, always set aside three.

The game in hand being thus reckoned, the eldest proceeds to play, reckoning one for every card he plays above nine, while the other

PICQUET.

follows him in the suit: but unless a card be won by one above nine, except it be the last trick, nothing is reckoned for it. The cards being played out, he that has most tricks reckons ten for winning the cards: but if they have tricks alike, neither reckons any thing. If one of them wins all the tricks, instead of ten, which is his right for winning the cards, he reckons forty, and this is called *capot*.

The deal being finished, each person sets up his game; they then proceed to deal again as before; cutting afresh each time for the deal: if both parties are within a few points of being up, the *carte blanche* is the first that reckons, then the point, then the sequences, then the quatorzes, then the tierces, and then the tenth cards. He that can reckon thirty in hand by *carte blanche*, points, quintes, &c. without playing, before the other has reckoned any thing, reckons ninety for them, and this is called a *repike*; and if he reckons above thirty, he reckons so many above ninety. If he can make up thirty, part in hand, and part in play, before the other has told any thing, he reckons for them sixty; and this is called a *repike*; and if he reckons above thirty, he reckons so many above ninety. If he can make up thirty, part in hand, and part in play, before the other has told any thing, he reckons for them sixty: and this is called a *repike*, whence the name of the game. Mr. de Moivre, in his doctrine of chances, has resolved, among others, the following problems: 1. To find, at picquet, the probability which the dealer has for taking one ace or more in three cards, he having none in his hands. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more. 2. To find at picquet the probability which the eldest has of taking an ace or more in five cards, he having no ace in his hands. Answer; 232 to 91, or 5 to 2, nearly. 3. To find at picquet the probability which the eldest has of taking both an ace and a king in five cards, he having none in his hand. Answer; the odds against the eldest hand taking an ace and a king are 331 to 315, or 21 to 20 nearly. 4. To find at picquet the probability of having twelve cards dealt to, without king, queen, or knave; which case is commonly called *cartes-blanches*. Answer; the odds against *cartes-blanches* are 1791 to 1 nearly. 5. To find how many different sets essentially different from one another, one may have at picquet before taking in. Answer; 28,967,278. This number falls short of the sum of all the distinct combinations, whereby twelve cards may be taken out of 32, this number 225,792,840: but it ought to be considered, that in that number several sets of the same import, but differing in suit, might be taken, which would not introduce an essential difference among the sets.

The technical terms used in picquet are as follows.

Capot is when either of the players makes every trick for which he scores forty.

Cards signify the majority of tricks, which reckon for ten points.

Carte Blanche means a hand without a court card in the twelve dealt, which counts for ten, and takes place of every thing else.

Huitième eight successive cards of the same suit, counts eighteen points.

Pique is when the elder hand has reckoned thirty in hand, and play before the adversary has gained one; in which case, instead of thirty, it is called sixty, adding thereto as many points as are obtained above thirty.

Point the greatest number on the cards of the same suit in hand, after having taken in, reckoned by their pips, scores for as many points as cards.

Quart four cards in sequence of the same suit counts four points: there are five kinds of quarts, the first called *quart-major*, consists of ace, king, queen, and knave; the second, quart from a king, of king, queen, knave, and ten; the third, quart from a queen, of queen, knave, ten, nine; the fourth, quart from a knave, of knave, ten, nine, eight; the fifth, a *basse-quart* or *quart-minor*, of ten, nine, eight, and seven.

Quatorze the four aces, kings, queens, knaves, or tens, scores fourteen points.

Quint means five cards of the same suit in sequence, and reckons fifteen points: there are four sorts of quints; a *quint-major* of ace, king, queen, knave, and ten, down to knave, ten, nine, eight, and seven, stiled a *quint-minor*.

Repike signifies when one of the players counts thirty or more in hand, before the adversary obtains one, then it is called ninety, reckoning as many points above ninety as were gained above thirty.

Sixième or six cards of the same suit in sequence, reckons for sixteen points: there are three sorts of *sixièmes*, viz. *sixième-major* from the ace, *sixième* from the king, and *sixième* minor from the queen.

Septieme or seven of the same suit in sequence, counts for seventeen points; there are two *septièmes*, one from the ace, the other from the king.

Threes of aces, &c. down to tens, reckon three points.

Talon or *Stock* means the eight remaining cards after twelve are dealt to each player.

Tierce or sequence of three, reckons for three: there are six kinds of tierces, *tierce-major*, of ace, king, queen; down to nine, eight, seven, stiled *tierce-minor*.

The following is the mode of playing the general game as given by Mr. Hoyle.

Play by the stages of your game; that is, when behind your adversary, play a pushing game, otherwise you ought to make twenty-seven points elder-hand, and thirteen points younger-hand; and always compare your game with your adversary's, and discard accordingly.

Discard in expectation of winning the cards, which generally make twenty-two, or twenty-three points difference; therefore don't discard for low quatorze, such as four queens, four knaves, or four tens, because in any of these cases the odds are three to one, elder-hand, and seventeen to three, younger hand, that you do

P I C Q U E T.

not succeed; for if you throw out an ace or a king, you run the risk of losing above twenty points, in expectation of winning fourteen.

At the beginning of a party, play to make your game, which is twenty-seven points elder-hand, and thirteen points younger-hand: suppose you are elder-hand, and have a tierce-major, and the seven of any suit, it is five to two but that you take in one out of any four certain cards; therefore if you have three queens, three knaves, or three tens, discard one of them preferably to the seven of such a suit, because it is 3 to 1 that you do not take in any one certain card, elder-hand, to make you a quatorze, and consequently you would discard the seven to great disadvantage.

If your adversary is considerably before you in the game, the consideration of the cards must be put quite out of the question: therefore suppose you should have a quart to a queen, or to a knave; it is only about 5 to 4, being elder-hand, but that you take in a card to make you a quint, and about 3 to 1 but that you take in a queen, a knave, or ten; and should you have three of either dealt you, push for the game, particularly if it is so far advanced as to give you but little chance in another deal; and in this, and other cases, have recourse to the calculations ascertaining the odds.

Gaining the point, generally makes ten difference; therefore when you discard endeavour to gain it, but do not risk losing of the cards.

Saving of your lurch, or lurching your adversary, is so material, that you ought always to risk some points to accomplish either of them.

If you have six tricks, with any winning card in your hand, play that card; because, at least, you would play 11 points to 1 against yourself by not so doing, unless in play you discover what cards your adversary has laid out.

If you are greatly advanced in the game, as 80 to 50, in that case let your adversary gain two points for one as often as you can, especially if in the next deal you are to be elder-hand; but if on the contrary you are to be younger-hand, and are 86 to 50 or 60, never regard losing two or three points for the gaining of one, because that point brings you within your shew.

The younger-hand is to play upon the defensive; therefore, in order to make his thirteen points, he is to carry tierces, quarts, and especially strive for the point: but suppose him to have two tierces, from a king, queen, or knave, as it is 29 to 23 that he succeeds, he having in that case four certain cards to take in to make him a quart to either of them, and, perhaps, thereby save a pique, &c. he ought preferably to go for that which he has the most chance to succeed in; but if he has three queens, knaves, or tens, and should attempt to carry any of them preferably to the others, the odds that he does not succeed being 17 to 3 against him, he consequently discards to a great disadvantage.

The elder or younger hand should sometimes sink one of his points, a tierce or three kings, queens, knaves, or tens, in hopes of winning

the cards: but that is to be done with judgment, and without hesitating.

It is often good play for a younger hand not to call three queens, knaves, &c. also to sink one card of his point, which his adversary may suppose to be a guard to a king or queen.

The younger-hand having the cards equally dealt him, is not to take in any card, if thereby he runs the risk of losing them, unless he is very backward and has then a scheme for a great game.

If the younger-hand has a probability of saving or winning the cards by a deep discard; as, for example, suppose he should have the king, queen, and nine, and the king, knave, and nine of a suit; in this case he may discard either of those suits, with a moral certainty of not being attacked in them; and the odds that he does take in the ace of either of those suits being against him, it is not worth while to discard otherwise in expectation of succeeding.

The younger-hand having three aces dealt him, it is generally best to throw out the fourth suit.

The younger-hand is generally to carry guard to his queens-suits, in order to make points, and save the cards.

When the younger-hand observes that the elder-hand, by calling his point, has five cards, which will make five tricks in play, and may also have the ace and queen of another suit, he should throw away the guard to the king of the same, especially if he has put out one of that suit, which will give him an even chance of saving the cards.

If the elder-hand has a quart to a king dealt him with two other kings and queens, and is obliged to discard either one of his quart to the king, or a king or queen, the chance for taking in the ace or nine to his quart being one out of two certain cards, is exactly equal to the taking either a king or a queen, having three of each dealt him; therefore he is to discard in such a manner as gives him the fairest probability of winning the cards. This may be a general direction in all cases of the like nature, either for the elder or younger hand.

Suppose the elder-hand has taken in his five cards, and has ace, king, and knave of a suit, having discarded two of the same; and has also the ace, king, knave, and two small cards of another, but no winning cards in the other suits, he then should always play from that of which he has the fewest in number; because, if his adversary proves guarded there, probably he is unguarded in the other; but should the elder-hand lead from the suit of which he has the most, and find his adversary's queen guarded, in that case he has no chance to save or win the cards.

If the elder-hand is sure to make the cards equal, by playing in any particular manner, and is advanced before his adversary in the game, he should not risk losing them; but if his adversary is greatly before him, in that case his interest is to risk losing of the cards, in expectation of winning them.

PICQUET.

The particular rules and cases worth attending to are as follow.

1. Suppose you, elder-hand, have dealt you a quart-major, with the seven and eight of clubs, and king and ten of diamonds, the king and nine of hearts, with the ten and nine of spades; then if you throw out one card of your point, there is a possibility that you reckon only five, and that your adversary may win the cards, by which he gets eleven points, besides his three aces, &c. which gives you a bad chance for the game; but by leaving a card, and admitting that one card of consequence lies in the five which you are entitled to take in, it follows, that you have four chances to one against leaving that particular card, and consequently it is your interest to leave a card: the odds are also greatly in your favour, that you take in some one of the following in your four cards, viz. there are two to your points, three aces, and one king.

2. If you should happen to have the ace, king, and four small cards of any suit, with two other kings, and no great suits against you, the like method of the former case may be practised.

3. Suppose you have the king, queen, and four of the smallest clubs, the king and queen of diamonds, the ace and knave of hearts, and the king and nine of spades, throw out the queen and four small clubs, and carry three entire suits with the king of clubs; for this reason, because the chance for your taking in the fourth king is exactly the same as the chance of taking in the ace of clubs; in either of which cases it is 3 to 1 against you: but if you fail of taking in the fourth king, you by discarding thus, have a fair chance to win the cards, which will probably make twenty-two points difference. But should you discard with an expectation of taking in the ace of clubs, and happen to fail, you being obliged to throw out some of your great cards would have a very distant chance of either saving or winning the cards.

4. Suppose you should have the king and queen of clubs, a tierce-major in diamonds, queen and knave of hearts, and a quint from the knave of spades, throw out the quint from a knave in order to make the most points; because, admit that your quint is good for every thing after you have taken in, you in that case only score nineteen points if you carry it, and you probably give the cards up, and also the chance of the quatorze of queens, besides a great number of points in play.

5. Suppose you have the king, queen, seven, eight, and nine of clubs; the queen and knave of diamonds; the queen, ten, and nine of hearts, with the ace and nine of spades, discard the king, seven, eight, and nine of clubs, and the nine of spades; by which you do not only go for three suits, but have the same chance for taking in the fourth queen, as you would have to take in the ace of clubs; besides, the probability of winning the cards is greatly in your favour.

6. Suppose you have the queen, ten, nine,

eight, and seven of clubs; the knave and ten of diamonds; the king, queen, and knave of hearts, with the ace and nine of spades, discard the five of clubs; because it is 3 to 1 that you do not take in the knave of clubs; and carrying three entire suits gives you a fairer chance to score more points.

7. Suppose you have the ace, queen, and knave of clubs; the king, queen, and knave of diamonds; the queen and knave of hearts with the ten, nine, eight, and seven of spades, discard the ace of clubs and the four spades, because it is only 5 to 4 but that you take in a queen or a knave; it is also about 3 to 2 that you take in an ace: you have also three cards to your tierce to a king to take in, viz. the ace and ten, or the ten and nine, to make you a quint; all which circumstances considered, you have a fair probability of making a great game: whereas, by throwing out the four spades only, you run the risk of leaving one of the following cards, viz. the king of clubs, the ace of diamonds, the ace, queen, or knave of spades; in any of which cases you would probably lose more points than by throwing out the ace of clubs; and if you should carry two suits, viz. three clubs, three diamonds, and the queen of hearts, you run the risk of putting out fourteen points; and it is only 5 to 4 against your taking in a queen or a knave, and therefore you would discard to a great disadvantage.

8. Suppose you have the king, queen, and ten of a suit, and your adversary has the ace, knave, and one small card of the same; and that you have only those three cards left, and are to make three points of them; play the ten.

9. Suppose you have the ace, queen, ten, and nine of clubs, also the king, queen, ten, and nine of diamonds, carry the king, queen, ten, and nine of diamonds; because the chance of taking in the ace or knave of diamonds is exactly equal to that of taking in the king or knave of clubs; by which manner of discarding you may perhaps score fifteen points for your quint in diamonds, instead of four for the quart in clubs: and the chance for winning the cards is better; because, by taking in the ace of diamonds you have seven tricks certain, which cannot happen by taking in the king of clubs.

10. Suppose you have four aces and two kings dealt you younger-hand; in order to capot the elder-hand, make a deep discard, such as the queen, ten, and eight of a suit; by which, if you happen not to take in any card to such suit, you may probably capot the adversary.

11. Suppose elder-hand, that you have the ace, queen, seven, eight, and nine of clubs, also the ace, knave, seven, eight, and nine of diamonds, carry the ace, knave, seven, eight, and nine of diamonds; because taking in the king of diamonds is equal to the taking in the king of clubs, and consequently as good for winning the cards; but you have the chance of taking in the ten of diamonds to make you

P I C Q U E T.

fifteen points, which cannot happen by taking in any one certain card in clubs.

12. Suppose elder-hand, that you have the ace, queen, seven, eight, and ten of clubs, also the ace, knave, seven, eight, and ten of diamonds, carry the ace, knave, seven, eight, and ten of diamonds, for the reasons given in No. 11.

13. Suppose you have the ace, queen, ten, and two more of any suit; also the ace, queen, and ten of another only, and that your adversary has shewn six cards for his point; suppose the ace, queen, and four small ones, and you are guarded in that suit; as soon as you have the lead, play from the suit of which you have the fewest for the reason before stated, because thereby you may obtain the cards; but if your opponent is guarded in both suits, you have no chance to win.

In discarding, it should be observed that, 1. The chance of an elder-hand taking in one certain card, is 3 to 1 against him.

2. That of his taking in two certain cards, is 18 to 1 against him.

3. The odds that an elder-hand takes in four aces, are against him 968 to 1; three of them is about 33 to 1, two of them 3 to 1: one of them 2 to 5.

4. If an elder-hand has one ace dealt him, the odds that he takes in the other three are against him 113 to 1; two of them about 6 to 1; one of them 2 to 3.

5. If an elder-hand has two aces dealt him, the odds that he takes in the other two are against him 18 to 1; one of them is near 5 to 4 against him, or 21 to 17.

6. In case the elder-hand has two aces and two kings dealt, the odds that he takes in either the two aces or two kings, are against him about 17 to 2.

7. Elder-hand having neither ace nor king dealt him, his chance to take in both an ace and a king in two cards, is against him about 11 to 1; in three cards 4 to 1; in four cards 9 to 5; in five cards 33 to 31.

8. The odds that a younger-hand takes in two certain cards are against him 62 to 1. The odds of three certain cards are against him 1139 to 1.

9. The younger-hand having no ace dealt, the chance for his taking one is against him 28 to 29.

10. If the younger-hand has one ace dealt, the odds of taking in two of the three remaining aces are against him about 21 to 1; one of them 3 to 2.

11. The odds that a younger-hand takes in one certain card are against him 17 to 3. The odds of a carte-blanche are against him 1791 to 1.

Laws of the Game of Picquet.—1. The elder-hand is obliged to lay out at least one card.

2. If the elder-hand takes in one of the three cards which belong to the younger-hand, he loses the game.

3. If the elder-hand, in taking his five cards, should happen to turn up a card belonging to the younger-hand, he is to reckon nothing that deal.

4. If the elder or younger-hand plays with thirteen cards, he counts nothing.

5. Should either of the players have thirteen cards dealt, it is at the option of the elder-hand to stand the deal or not, and if he chooses to stand, then the person having thirteen is to discard one more than he takes in; but should either party have above thirteen cards, then a new deal must take place.

6. If the elder or younger-hand reckons what he have not, he counts nothing.

7. If the elder-hand touches the stock after he has discarded, he cannot alter his discard.

8. If a card is faced, and it happens to be discovered, either in the dealing or in the stock, there must be a new deal, unless it be the bottom card.

9. If the dealer turns up a card in dealing, belonging to the elder-hand, it is in the option of the elder-hand to have a new deal.

10. If the younger-hand takes in five cards, it is the loss of the game, unless the elder-hand has left two cards.

11. If the elder-hand calls 41 for his point, which happens to be a quart-major, and it is allowed to be good, and only reckons 4 for it, and plays away, he is not entitled to count more.

12. If the elder-hand shews a point, or a quart, or tierce, and asks if they are good, and afterwards forgets to reckon any of them, it bars the younger-hand from reckoning any of equal value.

13. Carte-blanche counts first, and consequently saves piques and repiques. It also piques and repiques the adversary, in the same manner as if those points were reckoned in any other way.

14. Carte-blanche need not be shewn till the adversary has first discarded; only the elder-hand must bid the younger-hand to discard for carte-blanche: which, after he has done, shew your blanche by counting the cards down one after another.

15. You are to cut two cards at the least.

16. If the elder-hand calls a point, and does not shew it, it is not to be reckoned; and the younger-hand may shew and reckon his point.

17. If you play with eleven cards, or fewer, no penalty attends it.

18. If the elder-hand leaves a card, and after he has taken in, happens to put to his discard the four cards taken in, they must remain with his discard, and he only play with eight cards.

19. If the younger-hand leaves a card or cards, and mixes it with his discard before he has shewn it to the elder-hand, who is first to tell him what he will play, the elder-hand is entitled to see his whole discard.

20. If the younger-hand leaves a card or cards, and does not see them, nor mixes them to his discard, the elder-hand has no right to see them; but then they must remain separate whilst the cards are playing, and the younger-hand cannot look at them.

21. If the younger-hand leaves a card or

cards, and looks at them, the elder-hand is entitled to see them, first declaring what suit he will lead.

22. If the dealer deals a card too few, it is in the option of the elder-hand to have a new deal; but if he stands the deal, he must leave three cards for the younger-hand.

23. In the first place, call your point; and if you have 2 points, if you design to reckon the highest, you are to call that first, and are to abide by your first call.

24. You are to call your tierces, quarts, quints, &c. next; and to call the highest of them, in case you design to reckon them.

25. You are to call a quatorze preferably to three aces, &c. if you design to reckon them.

26. If you call a tierce, having a quart in your hand, you must abide by your first call.

27. Whoever deals twice together and discovers it previous to seeing his cards, may insist upon his adversary dealing, although the latter may have looked at his cards.

28. Should the pack be found erroneous in any deal, that deal is void; but the preceding deals are valid.

29. The player who at the commencement does not reckon or shew carte-blanche, his point, or any sequence, &c. is not to count them afterwards.

30. No player can discard twice, and after he has touched the stock, he is not allowed to take any of his discard back again.

31. When the elder-hand does not take all his cards, he must specify what number he takes or leaves.

32. Whosoever calls his game wrong and does not correct himself before he plays, is not to reckon any thing that game; but the adversary is to reckon all he has good in his own game.

33. Any card that has touched the board is deemed to be played, unless in case of a revoke.

34. If any player names a suit, and then plays a different one, the antagonist may call a suit.

35. The player who looks at any card belonging to the stock is liable to have a suit called.

PICRAMNIA, in botany, a genus of the class dioecia, order pentandria. Calyx three or five-parted; corol three or five-petalled. Female: styles two; berry two-celled; seeds in pairs. Two species; of which *P. antidesmia*, murjoe-bush, is chiefly worthy of notice. It is found frequent in the copses and about the skirts of woods in Jamaica, rising about eight or nine feet from the ground, with alternate, ovate pointed leaves; pendulous and slender flowers on long spikes; florets small and white; berries numerous, at first red, then jet black; pulp soft, purple colour. The negroes make a decoction of the berries, and drink it in dyspepsy and syphilis.

PICRANIA AMARA, or BITTER WOOD, is a tall and beautiful timber tree, common in the woods of Jamaica. It is a new genus, belonging to the pentandria monogynia of Linnéus.

The name is expressive of its sensible qualities. Every part of this tree is intensely bitter: and even after the tree has been laid for floors many years, whoever rub or scrape the wood feel a great degree of bitterness in their mouth or throat. Cabinet-work made of this wood is very useful, as no insect will live near it. This tree has a great affinity to the quassia amara of Linnéus; in lieu of which it is used as an antiseptic in putrid fevers. When used, less of it will do than of the quassia amara of Surinam. See **QUASSIA**.

PICRIS, Ox-tongue. In botany, a genus of the class syngenesia, order polygamia aequalis. Receptacle naked; down feathery, pedicelled; seeds transversely striate; calyx invested with scales. Six species, natives of Japan, Barbary, South of Europe; one, *P. hieracioides*, common ox-tongue, found wild in the borders of our own fields, with yellow blossoms, in most varieties closing soon after noon. It is an agreeable pot-herb while young. The juice is milky and mild.

PICTLAND. See **PENTLAND**.

PICTS, the name of one of those nations who anciently possessed the north of Britain. It is generally believed that they were so called from their custom of painting their bodies; an opinion which Camden supports with great erudition. (See Gough's edition, vol. 1. p. xci. of the preface.) It is certainly liable, however, to considerable objections; for, as this custom prevailed among the other ancient inhabitants of Britain, who used the glastum of Pliny and the vitrum of Mela for the like purpose, it may be asked, Why was the name of *Picti* confined by the Romans to only one tribe, when it is equally applicable to many others? Why should they design them only by an epithet, without ever annexing their proper name? Or why should they impose a new name on this people only, when they give their proper name to every other tribe which they have occasion to speak of? As these questions cannot be answered in any satisfactory manner, it is plain we must look for some other derivation of the name.

The Highlanders of Scotland, who speak the ancient language of Caledonia, express the name of this once famous nation by the term *Pictich*; a name familiar to the ears of the most illiterate, who could never have derived it from the Roman authors. The word *Pictich* means pilferers or plunderers. The appellation was probably imposed upon this people by their neighbours, or assumed by themselves, some time after the reign of Caracalla, when the unguarded state of the Roman province, on which this people bordered, gave them frequent opportunities of making incursions thither, and committing depredations. Accordingly this name seems to have been unknown till the end of the 3d century. Eumenius the panegyrist is the first Roman author who mentions this people under their new name of *Pictich*, or, with a Latin termination, *Picti*. When we say that this name may have been probably assumed for the reason just now mentioned,

we must observe that, in those days of violence, the character of a robber was attended with no disgrace. If he had the address to form his schemes well, and to execute them successfully, he was rather praised than blamed for his conduct; providing he made no encroachments on the property of his own tribe or any of its allies. We mean this as no peculiar stigma upon the Picts; for other nations of antiquity, in the like rude state, thought and acted as they did. See *Thucydides*, lib. 3. p. 3. and *Ving. Æn.* 7. 745—749.

Concerning the origin of the Picts, authors are much divided. Boethius derives them from the Agethyrsi, Pomponius Lætus from the Germans, Bede from the ancient Scythians, Camden and father Innes from the ancient Britons, Stillingfleet from a people inhabiting the Cimbrica Chersonesus, and Keating and O'Flaherty, on the authority of the Psalter Cashel, derive them from the Thracians. But the most probable opinion is, that they were the descendants of the old Caledonians. Several reasons are urged in support of this opinion by Dr. Macpherson; and the words of Eumenes, "Caledonum, aliorumque Pictorum, silvas," &c. plainly imply that the Picts and Caledonians were one and the same people.

As there has been much dispute about the origin of the Picts, so there has been likewise about their language. There are many reasons, however, which make it plain that their tongue was the Gaelic or Celtic; and these reasons are a further confirmation of their having been of Caledonian extract.

The Picts of the earliest ages, as appears from the joint testimony of all writers who have examined the subject, possessed only the east and north-east coast of Scotland. On one side, the ancient Drumalbin, or that ridge of mountains reaching from Lochlomond near Dumbarton to the frith of Taine, which separates the county of Sutherland from a part of Ross, was the boundary of the Pictish dominions. Accordingly we find in the life of Columba, that, in travelling to the palace of Brudius, king of the Picts, he travelled over Drumalbin, the Dorsum Britanniaæ of Adamnan. On the other side, the territory of the Picts was bounded by the Roman province. After Britain was relinquished by the emperor Honorius, they and the Saxons by turns were masters of those countries which lie between the frith of Edinburgh and the river Tweed. We learn from Bede, that the Saxons were masters of Galloway when he finished his Ecclesiastical History. The Picts, however, made a conquest of that country soon after; so that, before the extinction of their monarchy, all the territories bounded on the one side by the Forth and Clyde, and on the other by the Tweed and Solway, fell into their hands.

The history of the Picts, as well as of all the other ancient inhabitants of Britain, is extremely dark, so that we may very well be excused for not dwelling upon it in this place.

PICTS WALL, in antiquity, a wall begun

by the emperor Adrian, on the northern bounds of England, to prevent the incursions of the Picts and Scots. It was first made only of turf strengthened with palisades, till the emperor Severus, coming into Britain in person, built it with solid stone. This wall, part of which still remains, began at the entrance of the Solway Frith in Cumberland, and running north-east extended to the German ocean at Tinmouth. See **ADRIAN** and **SEVERUS**.

PICTORIAL. *a.* (from *pictor*, Lat.) Produced by a painter (*Brown*).

PICTURE. *s.* (*pictura*, Lat.) 1. A resemblance of persons or things in colours (*Shaks.*). 2. The science of painting. 3: The works of painters (*Stillingfleet*). 4. Any resemblance or representation (*Locke*).

To PICTURE. *v. a.* (from the noun.) 1. To paint; to represent by painting (*Shaks.*). 2. To represent (*Spenser*).

PICUMNUS, and **PILUMNUS**, two deities at Rome, who presided over the auspices, that were required before the celebration of nuptials. Pilumnus was supposed to patronize children. The manuring of lands was invented by Picumnus, from which reason he is called Sterquilinus. Pilumnus is also invoked as the god of bakers and millers, as he is said to have first invented how to grind corn. Turnus boasted of being one of his lineal descendants.

PICUS, a king of Latium, son of Saturn, who married Venilia, also called Caneus, by whom he had Faunus. As he was one day hunting in the woods, he was met by Circe, who became deeply enamoured of him, and who changed him into a woodpecker, called by the name of *picus* among the Latins. His wife Venilia was so disconsolate when she was informed of his death, that she pined away.

PICUS. Woodpecker. In zoology, a genus of the class aves, order picæ. Bill angular, straight, wedged at the tip; nostrils covered with recumbent, setaceous feathers; tongue round, worm-shaped, very long, bony, missile, daggered, beset at the point with bristles bent back; tail-feathers ten, hard, rigid, pointed; feet made for climbing.

The birds of this genus climb up and down trees in search of insects, which they transfix and draw out from the clefts of the bark by means of the tongue, which is long at the end, barbed, and furnished with a curious apparatus of muscles, for the purpose of throwing it forward with great force. The life of the woodpecker appears therefore to be harder and less pleasurable than that of most birds. Condemned to this painful toil, he can obtain no food but by boring the bark and hard fibres of trees that inclose it. Thus continually occupied, he enjoys neither relaxation nor rest; and often sleeps in the constrained attitude in which he spent the day. He shares in none of the agreeable sports of the rest of the tenants of the air; he enters into none of their concerts; he utters only savage cries, or plaintive accents, which interrupt the silence of the forest, and express the efforts of a life of fatigue

and of pain. The manners of this bird are suited to its condition : its air is disconsolate ; the traits of its visage harsh. The dispositions of the woodpecker are wild and savage. He flies from society, even that of his mate ; and when forced by the impulse of the sexual appetite to seek a companion, he does it without that graceful address, with which this passion animates creatures of more sensibility.

Such are the condition and habits of the woodpecker. Nature, however, amidst her unkindness, has not denied him instruments suited to his destiny. His legs are strong and muscular ; and the disposition of his toes, of which two are before, and two backward, is fitted for a vigorous adhesion to the trunks of trees where his work lies. His bill, square at the base, but flattened laterally towards the top, like a pair of scissors, is the instrument by which he cuts the trunks of trees, where the insects deposit their eggs. From his bill he darts out his long, round tongue, armed at the top with a sharp bony substance, like a needle ; and with this instrument he stabs and draws out the small worms found in the timber. His nest is constructed of dust, in the cavity which he has dug ; and it is from the heart of the tree that the progeny issues, which is destined to creep around and gnaw it down.

The genus comprises fifty-eight species, scattered over the globe, but chiefly inhabitants of America ; five or six are natives of our own country. We shall select a few specimens.

1. *P. martius*. Great black woodpecker. Black ; cap vermilion. Inhabits our own country, and Europe generally, and found in Chili ; resides chiefly among poplar trees ; builds a large and deep nest, and lays from two to three white eggs ; feeds principally on bees and ants ; from seventeen to eighteen inches long. In the female, the hind-head only is red.

These birds strike with such force against the trees which they excavate, that their noise is heard as far as that of a wood-cutter's hatchet. They sometimes make a large cavity in the interior part of a tree, which weakens it so much, that it falls with the first gale of wind : and hence they often occasion considerable damage to the proprietors of woods.

The bird frequently employs this cavity for a nest : which it makes large and commodious, as may be judged from the heaps of broken chips, which are seen at the foot of the tree which has been thus hollowed out. Aristotle asserts, that none of the woodpeckers ever alight upon the ground ; and it must be admitted, that they are seldom seen there. In winter, birds of this species regularly disappear ; the ants and insects penetrating, in these colder months, into the wood so deeply, that they cannot easily be dug out.

2. *P. principalis*. White-billed woodpecker. Black ; crest scarlet ; line on each side of the neck and secondary quill-feathers white ; bill as white as ivory ; irids yellow ; crest conic ; lower part of the back white. In the female the cap not coloured. Inhabits America from New Jersey to Brazil ; sixteen inches long :

by the Spaniards this species is called the Carpenter-bird, from the peculiar nature of his toils. Like the preceding, he is heard at work at a great distance, and according to Catesby will make a bushel of chips in an hour or two.

3. *P. erythrocephalus*. Red-headed woodpecker. Head wholly red ; wings and tail black ; belly white. In the female the head brown. Inhabits North America ; nine and a half inches long ; migrates, and feeds on acorns, fruits, and Indian corn. Makes the same loud sawing noise when at work as *P. martius* : Catesby affirms that this noise can be heard a mile off. In the winter grows tame, and like the redbreast, will enter houses for food.

4. *P. auratus*. Golden-winged woodpecker. Transversely striate, with black and grey ; chin and breast black ; nape red, rump white ; bill black, round, a little curved ; hind-head and cheeks red ; upper part of the breast with a black lunule ; rest of the breast and belly whitish spotted with black ; back and wing-coverts pale brown with black lines ; first quill-feathers cinereous beneath, and shafts golden ; tail black, edged with white ; legs dusky. Female, chin cinereous. Inhabits North America : eleven inches long ; migrates to Hudson's Bay ; feeds on worms and ground insects, and for want of these, on berries and grass : does not climb trees.

5. *P. viridis*. Green woodpecker. Green : crown crimson. Another variety, with the upper part of the head and spots beneath the ears deep red ; rump pale yellow ; bill dusky, two inches long ; inner circle of the irids reddish, outer white ; temples blackish ; quill feathers dusky with whitish spots ; tail blackish, obscurely barred with green, and tipped with white ; legs greenish-ash. The first inhabits Europe, and is found in our own country ; the second Mexico. Thirteen inches long ; makes a circular hole in the dead parts of trees for its nest ; and lays from five to six greenish eggs spotted with black ; is fond of bees.

6. *P. pubescens*. Downy woodpecker. Back longitudinally downy ; outer tail feathers white with four black spots ; hind head red in the male. Inhabits North America in vast flocks ; is bold, and very injurious to orchards by piercing and destroying the trees : making one hole close to another in a horizontal line, till it has completed a circle of holes all round the tree. Size that of a sparrow.

PID AURA, a town of Turkey in Europe, in the Morea, the ancient Epidaurus. It is situate on the W. coast of the gulf of Engia, 25 miles E. of Napoli-di-Romania. Lon. 23. 22 E. Lat. 37. 40 N.

To PIDDLE. *v. n.* (perhaps from *peddle*.) 1. To pick at table ; to feed squeamishly, and without appetite (*Swift*). 2. To trifle ; to attend to small parts rather than to the main (*Ainsworth*).

PIDDLER. *s.* (from *piddle*.) 1. One that eats squeamishly and without appetite. 2. One who is busy about minute things.

PIE. *s.* 1. Any crust baked with something in it. 2. (*pica*, Latin.) A magpie; a party-coloured bird (*Shakspeare*). 3. The old popish service book, so called from the different colours of the text and rubric. 4. Cock and pie, was a slight expression in *Shakspeare's* time, of which we know not the meaning.

PIEBALD. *a.* (from *pie*.) Of various colours; diversified in colour (*Pope*).

PIECE. *s.* (*piece*, French.) 1. A patch (*Ainsworth*). 2. A part of a whole; a fragment (*Acts*). 3. A part (*Tillotson*). 4. A picture (*Dryden*). 5. A composition; performance (*Addison*). 6. A coin; a single piece of money (*Prior*). 7. **A-PIECE.** To each (*More*). 8. *Of a PIECE with.* Like; of the same sort; united; the same with the rest (*Dryden*).

PIECES, in the military art, include all sorts of great guns and mortars. Battering pieces are the larger sort of guns used as sieges for making the breaches, such are the twenty-four pounder, and culverin, the one carrying twenty-four, and the other an eighteen pound ball. Field pieces are twelve-pounders, demi-culverins, six-pounders, sakers, minions, and three-pounders, which march with the army, and encamp always behind the second line, but in the day of battle are in the front. A soldier's firelock is likewise called his piece.

To PIECE. *v. a.* (from the noun.) 1. To enlarge by the addition of a piece (*Shakspeare*). 2. To join; to unite. 3. **To PIZCE out.** To increase by addition.

To PIECE. *v. n.* To join; to coalesce; to be compacted (*Bacon*).

PIE/CER. *s.* (from *piece*.) One that pieces.

PIE/CELESS. *a.* (from *piece*.) Whole; compact; not made of separate pieces (*Donne*).

PIE/CEMEAL. *ad.* (*piece* and *mel*, Sax.) In pieces; in fragments (*Pope*).

PIE/CEMEAL. *a.* Single; separate; divided (*Government of the Tongue*).

PIED. *a.* (from *pie*.) Variegated; party-coloured (*Drayton*).

PIEDMONT, a principality of Italy, 175 miles long and 40 broad; bounded on the N. by Vallais, on the E. by the duchies of Milan and Montferrat, on the S. by the county of Nicé and the territory of Genoa, and on the W. by France and Savoy. It was formerly a part of Lombardy, but now belongs to the king of Sardinia. It lies at the foot of the Alps, and contains many high mountains, among which are rich and fruitful vallies, as populous as any part of Italy. In the mountains are mines of several kinds, and the forests afford a great deal of game. This country has a great trade in raw silk; and it produces also corn, rice, wine, fruits, hemp, flax, and cattle. Turin is the capital.

PIEDNESS. *s.* (from *pied*.) Variegation; diversity of colour (*Shakspeare*).

PIE/LED. *a.* Bald (*Shakspeare*).

PIENZA, a populous town of Tuscany, in the Siennese, with a bishop's see; 25 miles S.E. of Sienna, and 56 S. of Florence. Lon. 11. 42 E. Lat. 43. 0 N.

PIEPOUDRE (Court of), the lowest, and

at the same time the most expeditious court of justice known to the law of England. It is called piepoudre, (*curia pedis pulverizati*), from the dusty feet of the suitors; or, according to sir Edward Coke, because justice is there done as speedily as dust can fall from the foot; upon the same principle that justice among the Jews was administered in the gate of the city, that the proceedings might be the more speedy, as well as public. But the etymology given us by a learned modern writer is much more ingenious and satisfactory; it being derived, according to him, from *pied pultreaux*, a pedlar, in old French, and therefore signifying the court of such petty chapmen as resort to fairs or markets. It is a court of record, incident to every fair and market; of which the steward of him who owns or has the toll of the market is the judge. It was instituted to administer justice for all commercial injuries done in that very fair or market, and not in any preceding one. So that the injury must be done, complained of, heard, and determined, within the compass of one and the same day, unless the fair continues longer. The court hath cognizance of all matters of contract that can possibly arise within the precinct of that fair or market; and the plaintiff must make oath that the cause of an action arose there. From this court a writ of error lies, in the nature of an appeal, to the courts at Westminster.

PIER, in building, denotes a mass of stone, &c. opposed by way of fortress against the force of the sea, or a great river, for the security of ships lying in any harbour or haven. Such are the piers at Dover, or Ramsgate, or Yarmouth, &c.

PIERS are also used in architecture for a kind of pilasters, or buttresses, raised for support, strength, and sometimes for ornament.

PIERS (Circular), are called massive columns, and are either with or without caps. These are often seen in Saracenic architecture.

PIERS OF A BRIDGE, are the walls built to support the arches, and from which they spring as bases, to stand upon.

Piers should be built of large blocks of stone, solid throughout, and cramped together with iron, which will make the whole as one solid stone. Their extremities, or ends, from the bottom, or base, up to high-water mark, ought to project sharp out with a salient angle, to divide the stream. Or perhaps the bottom part of the pier should be built flat or square up to about half the height of low-water mark, to encourage a lodgment against it for the sand and mud, to cover the foundation; lest, being left bare, the water should in time undermine and ruin it. The best form of the projection for dividing the stream, is the triangle; and the longer it is, or the more acute the salient angle, the better it will divide it, and the less will the force of the water be against the pier; but it may be sufficient to make that angle a right one, as it will render the masonry stronger, and in that case the perpendicular projection will be equal to half the breadth or thickness of the pier. In rivers where large heavy craft

navigate, and pass the arches, it may perhaps be better to make the ends semicircular; for though this figure does not divide the water so well as the triangle, it will better turn off, and bear the shock of the craft. See Hutton's Treatise on Bridges.

To **PIERCE**. *v. a.* (*piercer*, French.) 1. To penetrate; to enter; to force a way into (*Dryden*). 2. To touch the passions; to affect (*Shakspeare*).

To **PIERCE**. *v. n. 1.* To make way by force into, or through any thing (*Bacon*). 2. To strike; to move; to affect (*Shakspeare*). 3. To enter; to dive as into a secret (*Sidney*). 4. To affect severely (*Shakspeare*).

PIERCE (Edward), a painter, eminent in history and landscapes, in the reign of Charles I. He had considerable skill also in architectural designs, but the fire of London in 1666 destroyed most of his works. The late ceiling of Covent-garden church exhibited the excellency of his pencil. He died in London about 1715.

PIERCE (James), a learned non-conformist divine; born at Exeter. He distinguished himself by A vindication of the Protestant Dissenters, published in Latin, in answer to Dr. Nicholls, which was published in English, in 1717. But his greatest work was A commentary on St. Paul's epistles. He died about 1730.

PIERCER. *s.* (from *pierce*.) 1. An instrument that bores or penetrates. 2. The part with which insects perforate bodies (*Ray*). 3. One who perforates.

PIERCINGLY. *ad.* (from *pierce*.) Sharply.

PIERCINGNESS. *s.* (from *piercing*.) Power of piercing (*Derham*).

PIERIA, a small country of Thessaly, said to be the birthplace of the Muses.

PIERIDES, a name given to the Muses, either because they were born in Pieria, in Thessaly, or because they were supposed by some to be the daughters of Pierus, a king of Macedonia, who settled in Boeotia.—Also, the daughters of Pierus, who challenged the Muses to a trial in music, in which they were conquered, and changed into magpies. The victorious Muses perhaps assumed the name of Pierides, in the same manner as Minerva was called Pallas, because she had killed the giant Pallas.

PIERINO, a Tuscan painter, born about 1500. His father was a soldier and his nurse a she goat. He was taken to Rome by a painter of the name of Vaga, from whom he was called del Vaga: while there, he obtained the notice of Raphael, who employed him. The plague drove him from Rome to Florence; but upon Raphael's death, he went back and finished some work left incomplete by that great artist. The prince Doria employed him to paint a palace then building at Genoa, and here it was he made use of cartoons. He died in 1547.

PIERRE LE MOUTIER (St.), a town of France, in the department of Nievre, seated

in a bottom, surrounded by mountains, and near a lake, which renders the air unwholesome, 15 miles N.W. of Moulins, and 150 S. of Paris. Lon. 3. 13 E. Lat. 46. 48 N.

PIERRE (St.), a small desert island near Newfoundland, ceded to the French in 1763, for drying and curing their fish. They were dispossessed of it by the English in 1793. Lon. 56. 0 W. Lat. 46. 39 N.

PIERRE (St.), the capital of Martinico, on the W. side of the island. Lon. 61. 21 W. Lat. 14. 44 N.

PIERSON (Christopher), a Dutch painter, born at the Hague, in 1631, and studied under Bartholomew Maypeny, whom he accompanied to Germany. He painted history and portraits very well, but excelled chiefly in hunting subjects. He died in 1714.

PIERUS, a mountain of Thessaly, sacred to the Muses, who were from thence, as some imagine, called Pierides.—2. A rich man of Thessaly, whose nine daughters, called Pierides, challenged the Muses, and were changed into magpies, when conquered.

PIETAS, a virtue which denotes veneration for the deity, and love and tenderness to our friends. It received divine honours among the Romans, and was made one of their gods. Acilius Glabrio first erected a temple to this divinity, on the spot where a woman had fed with her milk her aged father, imprisoned by the senate, and deprived of all aliments.

PIETISTS, a religious sect sprung up among the protestants of Germany, seeming to be a kind of mean between the quakers of England and the quietists of the Roman church. They despise all sorts of ecclesiastical polity, all school theology, and all forms and ceremonies, and give themselves up to contemplation and the mystic theology. Many gross errors are charged on the pietists, in a book entitled *Manipulis Observationum Antipietisticarum*: but they have much of the air of polemical exaggeration, and are certainly not at all just. Indeed there are pietists of various kinds: some running into gross illusions, and carrying their errors to the overturning of a great part of the christian doctrine, while others are only visionaries; and others are very honest and good, though perhaps misguided, people. They have been disgusted with the coldness and formality of other churches, and have thence become charmed with the fervent piety of the pietists, and attached to their party, without giving into the grossest of their errors. See Mosheim's *Eccles. History*, vol. iv. p. 454.

PIETY. *s.* (*pietas*, Latin; *piété*, French.) 1. Discharge of duty to God (*Peachment*). 2. Duty to parents or those in superiour relation (*Swift*).

PIG, in zoology. See *Sus*.

PIG (Guinea). See *Mus*.

PIG OF LEAD, the eighth part of a fother, amounting to 250 lb. weight.

To **PIG**. *v. a.* (from the noun.) To farrow; to bring pigs.

PIGEON, in ornithology. See *COLUMBA*.

PIGEON.

It is an observation made by a learned naturalist, that the pigeon is one of those birds which, from its great fecundity, has in some measure been reclaimed from a state of nature, and taught to live in habits of dependance. It is true, indeed, its fecundity seems to be increased by human assiduity, since those pigeons that live in their native state, in the woods, are not near so fruitful as those in our pigeon-houses nearer home. The power of increase in most birds depends not only upon the quantity, but also the quality, of their food; many instances may be shown, that man, by a judicious alteration of diet, and supplying food in plenty, and allowing the animal a proper share of freedom, has brought some of those kinds which seldom lay but once a year to become much more prolific.

The beautiful varieties of the tame pigeon are so numerous, that it would be a fruitless attempt to describe them all; for human art has so much altered the colour and figure of this bird, that pigeon-fanciers, by pairing a male and female of different sorts, can, as they express it, breed them to a feather. Hence we have the various names expressive of their several properties, such as carriers, tumblers, pouters, horsemen, croppers, jacobines, owls, nuns, runts, turbits, barbs, helmets, trumpeters, dragons, finnikins, &c. all birds that at first may have accidentally varied from the stockdove; and, by having these varieties still improved by pairing, food, and climate, the different species have been propagated. But there are several species of the wild pigeon which bear a near affinity to the stockdove, yet differ sufficiently from it to require a distinct description. The dove-house pigeon breeds every month; but when the weather is severe, and the fields covered with snow, it must be supplied with food. At other times it may be left to itself, and generally repays the owner for his protection. The pigeon lays two white eggs, which produce young ones of different sexes. When the eggs are laid, the female sits fifteen days, not including the three days she is employed in laying, and is relieved at intervals by the male. The turns are generally pretty regular. The female usually sits from about five in the evening till nine the next morning; at which time the male supplies her place, while she is seeking refreshment abroad. Thus they sit alternately till the young are hatched. When hatched, the young only require warmth for the first three days; a task which the female takes entirely upon herself, and never leaves them except for a few minutes to take a little food. After this they are fed for about ten days with what the old ones have picked up in the fields, and kept treasured in their crops, from whence they satisfy the craving appetites of their young ones, who receive it very greedily.

This way of supplying the young with food from the crop, in birds of the pigeon kind, differs from all others. The pigeon has the largest crop of any bird, for its size; which is also peculiar to its kind. In two that were dissected, it was found, that upon blowing the air into the wind-pipe, it distended the crop, or gullet, to an enormous bulk. This was the more singular, as there did not appear to be the least communication between those two receptacles. By what channel the air passed into the crop, we are wholly ignorant; but we have ocular demonstration, that these birds have a power of swelling the crop with air, and those called crop-

pers distend it in such a manner, that the bird's breast appears larger than its body. The necessity for it in these species is pretty clear, though the mechanism is not known. Pigeons live entirely upon grain and water: these being mixed together in the crop, are digested in proportion as the bird lays in its provision. Young pigeons are very ravenous, which necessitates the old ones to lay in a more plentiful supply than ordinary, and to give it a sort of half-maceration in the crop, to make it fit for their tender stomachs. The numerous glands, assisted by air, and the heat of the bird's body, are the necessary apparatus for secreting a milky fluid; but as the food macerates, it also swells, and the crop is considerably dilated. If the crop were filled with solid substances, the bird could not contract it; but it is obvious the bird has a power of compressing its crop at pleasure, and by discharging the air, can drive the food out also, which is forced up the gullet with great ease. The young usually receive this tribute of affection from the crop three times a day. The male for the most part feeds the young female, and the old female performs the same office for the young male. While the young are weak, the old ones supply them with food macerated, suitable to their tender frame; but as they gain strength the parents give it less preparation, and at last drive them out, when a craving appetite obliges them to shift for themselves; for when pigeons have plenty of food, they do not wait for the total dismission of their young; it being a common thing to see young ones fledged, and eggs hatching, at the same time, and in the same nest.

Though the constancy of the turtle-dove is proverbial, the pigeon of the dove-house is not so faithful, and having become subject to man, puts on incontinence among its other domestic qualities. Perhaps our knowledge of this supposed difference may arise from our greater familiarity with the habits of tame pigeons than of wild ones. Two males are often seen quarrelling for the same mistress; and when the female encourages the freedoms of a new gallant, her old companion shows visible marks of his displeasure, quits her company, or if he approach, it is only to chastise her. Many instances have been known where two males being dissatisfied with their respective mates, have thought fit to make an exchange, and have lived in peace and friendship with the new objects of their choice. So rapid is the fertility of this bird in its domestic state, however incredible it may appear, that from a single pair fourteen thousand seven hundred and sixty may be produced in the space of four years. The stock-dove, however, very rarely breeds more than twice a year: for, as the winter months approach, their whole employ is for self-subsistence, so that they cannot transmit a progeny. But their attachment to their young is much stronger than in those which breed often. This is owing, perhaps, to their affections being less divided by so great a number of claims.

Pigeons are very quick of hearing, have a very sharp sight, and when pursued by the hawk or kite, and are obliged to exert themselves, are exceedingly swift in flight. It is the nature of pigeons to love company and assemble in flocks, to bill in their courtship, and to have a plaintive note.

Mr. Duhamel asserts, "that pigeons do not feed upon the green corn, and that their bills have not strength enough to search for its seed

PIGEON.

in the earth; but only pick up the scattered grains, which would be parched up by the heat of the sun, or infallibly become the prey of other animals." He further adds, "that from the time of the sprouting of the corn, pigeons live chiefly upon the seeds of wild uncultivated plants, and therefore considerably lessen the quantity of weeds that would otherwise encumber the ground; as is evident from a just estimate of the quantity of grain necessary to feed all the pigeons of a well-stocked dove-house." But the facts alleged by Mr. Worlidge and Mr. Lisle, in support of the contrary opinion, are incontrovertible. Mr. Lisle relates that a farmer of his acquaintance, who was a man of strict veracity, assured him he had been witness to an acre sowed with peas, which the wet weather prevented being harrowed in, and every pea had been taken away in half a day's time by a flock of pigeons; and Mr. Worlidge says, "It is to be observed, that, where the flight of pigeons fall, there they fill themselves and away, and return again where they first rose, and so proceed over a whole piece of ground, if they like it. Although you cannot perceive any grain above the ground, they know how to find it, and consequently commit great depredations on the property of the farmer."

The following are the names and characters of the most esteemed pigeons.

The English powder.—This bird derives its name from having been originally bred in England, and is a cross breed between a horseman and a cropper. The frequency of pairing its young ones with the cropper has added great beauty to this bird, and raised its value among the fanciers.

Those composed of different colours are most esteemed, as the blue-pied, black-pied, red-pied, and yellow-pied. All these properties rise in estimation, according as they are more or less beautifully variegated.

The Dutch cropper.—This pigeon was originally bred in Holland; the body is thick, clumsy, and short, as are also the legs, which are feathered down to the feet: they have a large pouch or bag hanging under their beak, which they can swell with wind, or depress, at pleasure; their crop hangs low, but is very large; they are so loose-feathered on the thighs, as to be styled flag-thighed; they seldom play upright, and stand wide on their legs; they are gravel-eyed, and such bad feeders of their young, that, as soon as they have fed off their soft meat, it is necessary to place their young under a pair of small runts, dragons, or powting horsemen, who will rear them with more care than their real progenitors.

The uploper.—This is also a native of Holland; it nearly resembles the English powder in all its properties, only that it is smaller; it has a round crop, in which it generally hides its bill; it has small slender legs, with its toes short and close together, on which it trips so exactly, when walking, as to leave the ball of the foot quite hollow; it plays very upright, is close thighed, and has a custom on approaching the hen of leaping to her with the tail spread, whence the name uploper is derived.

The Parisian powder.—Though brought into England from Brussels, this is originally a native of Paris; it partakes of the nature of the English powder, though it is not so well made; its body and legs are short; it has generally a long, but not a large, crop; and is thick in the girth.

The powting horseman.—This is what the growers term a bastard-bred pigeon, and is produced between the horseman and the cropper; and, agreeably to the number of times that their young ones are bred over to the cropper, they have the appellation of first, second, or third breed; and the more frequently this method is practised, the greater is the improvement the crop receives from it.

The carrier.—These are rather larger than most of the common-sized pigeons; their feathers lie very close, even, and smooth; their flesh is naturally firm, and their necks long and straight; so that when they stand upright on their legs, they show an elegant gentility of shape far exceeding most other pigeons, who in such a posture cringe themselves up in an uncouth manner. From the lower part of the head to the middle of the lower chap there grows out a white, naked, fungous flesh, which is called the wattle, and is generally met by two small protuberances of the same luxuriant flesh, rising on each side of the under chap; this flesh is always most valued when of a blackish colour.

The circle round the black pupil of their eyes is commonly of a red brick-dust colour, though they are more esteemed when it is of a fiery red; these are also encompassed with the same sort of naked fungous matter, which is very thin, generally of the breadth of a shilling, and the broader this spreads, the greater is the value set upon them; but when this luxuriant flesh round the eye is thick and broad, it denotes the carrier to be a good breeder, and one that will rear very fine young ones. The pigeon-fanciers are unanimous in giving this bird the title of "king of the pigeons," on account of its graceful appearance and uncommon sagacity.

Extraordinary attention was formerly paid to the training of these pigeons, in order to their being sent from the garrison of a besieged city to generals that were coming to succour it: or from princes to their subjects with the news of some important transaction. In this country these aerial messengers have been made use of for a very singular purpose, being let loose at places of execution, at the moment the fatal cart was drawn away, to notify to distant friends the exit of the unhappy criminal; just as when some hero was to be interred, it was a custom among the ancient Romans to let fly an eagle with the funeral pile, to make his apotheosis complete.

In order to train a pigeon for this purpose, take a strong full-fledged, young carrier, and convey it in a basket or bag about half a mile from home, and there turn it loose; having repeated this two or three times, then take it two, four, eight, ten, or twenty miles, and so on till they will return from the remote parts of the kingdom. For if they be not practised when young, the best of them will fly but insecurely, and stand a chance of being lost: be careful that the pigeon intended to be sent with the letter is kept in the dark, and without food, for about eight hours before it is let loose, when it will immediately rise, and turning round, as is their custom, will continue on the wing till it has reached its home.

The horseman.—This bird is in shape and make very like the carrier, only less in all its properties, its body smaller, its neck shorter; neither is there so much luxuriant encrusted flesh upon the beak, and round the eye, so that the distance between the wattle and the eye is much more conspicuous.

PIGEON.

in this pigeon than in the carrier. They are also more subject to be barrel-headed and pinch-eyed. This species of the pigeon is decorated with a variety of colours; but the most distinguished are the blue and blue-pieds, which generally prove the best breeders. These pigeons, especially when young, should be regularly flown twice a day, and as they gain strength, should be let loose and put on the wing without any other in company, and they will fly four or five miles distance, in a few minutes, sweeping over a very large circuit. This is what the fanciers term going an end: this method is of essential service to them, especially when they are in training. This is the sort of pigeon chiefly made use of in this country, for deciding bets or conveying letters. The true genuine carriers are at this time very scarce, and of too great a value to be flown, except upon great emergencies. There is another species called the

Dragon.—It is bred between a tumbler, and a horseman, and the ablest fanciers are unanimous in their opinions, as to its being of a bastard-strain, and that by frequently matching their breed to the horseman, they will acquire great strength and agility. This pigeon is an excellent breeder, and makes a very tender nurse; for which purpose they are frequently kept as feeders for rearing of young powters, Leghorn-runts, and some other pigeons, who either breed so fast that they cannot conveniently give their young ones due attendance, or are destitute of that natural fondness which is the characteristic of this bird.

The tumbler.—These pigeons by their flight afford great amusement, for besides their tumbling, they will frequently rise to such an amazing height in the air as to be almost imperceptible to the keenest eye; and there is one peculiar property belonging to them, which is, that they will not ramble far like the horsemen, but if good birds, and familiarised to each other, will keep such close company, that a flight of a dozen may be covered with a handkerchief. At this height, especially if the weather be warm and clear, they will continue upon the wing for four or five hours at a stretch; it is reported that some well-bred pigeons of this sort have flown for nine hours successively, when they have been up at their highest pitch; the favourite sort seldom or never tumble but when they are beginning to rise, or when they are coming down to pitch.

The almond tumbler.—This is a very beautiful and valuable species, and derives its origin from the common tumblers, (which it so resembles in shape and make as to render any description unnecessary). By being judiciously matched, the feathers become very elegantly variegated with yellows, duns, whites, blacks, black-grizzled, black-splashed, &c.

The Leghorn runt.—This is a noble, large, full-bodied pigeon; it is close feathered, short in the back, very broad-chested, and frequently measures seven inches and a quarter in the length of its legs; when it walks, it carries its tail raised up like a duck's, but hangs it down when it plays. It is goose-headed, and hollow-eyed, with a longer neck than any other pigeon, which it carries bending like a goose; the eye is encircled with a thin skin, broader than that of the Dutch tumbler; the beak is very short, with a small wattle over the nostril, and the upper chap projects a little over the under.

The Spanish runt.—Is a short, thick-legged, flabby-fleshed, loose-feathered bird, with a remark-

ably long body; some of them measuring twenty-three inches in length from the apex of the beak to the extreme end of the tail; and it does not carry itself so upright as the Leghorn runt. The feathers of this variety are so uncertain, and of such a multiplicity of colours, that a judgment cannot be formed of the sort by the colour, though some of the best are reported to be of a blood-red or mottled hue.

The runt of Friesland.—This bird is somewhat larger than a middle-sized runt; its feathers are all inverted, and stand the wrong way: if this pigeon have its fanciers, it must be because it is uncommon and disgusting. It is at present very scarce in this country.

The trumpeter.—This pigeon is nearly as big as a middle-sized runt, and very like it in shape and make; its legs and feet are covered with feathers, the crown of its head is very round, like that of the finnikin and nun, only larger; and the larger the head is the more it is esteemed, as being usually more melodious; it is in general pearl-eyed, and black mottled in its feathers; but the surest mark to distinguish a good trumpeter is the tuft of feathers which sprout from the root of the beak, and the larger this tuft grows the greater is the value set upon the bird. The more salacious it is, the more it will trumpet: it derives its name from its imitating the sound of a trumpet, after playing, which it always does in the spring of the year.

This bird and the ensuing species of pigeons are called toys by amateurs.

The spot.—It has its name from a spot above its beak upon the top of its head; the tail-feathers are for the most part of the same colour with the spot, but the body is generally all white.

The laughter.—This bird in shape and make very much resembles a middle-sized runt; its plumage is generally red-mottled, but sometimes blue, and it has a very bright clear pearl eye, inclining to white.

The nun.—Its head is almost covered with a veil of feathers, whence its name. Its body is chiefly white; its head, tail, and the six flight-feathers of its wings, should be entirely red, yellow, or black: that is, when its head is red its flight and tail should be red also; and when its head is yellow its flight and tail should be yellow; and when its head is black its flight and tail should also be of this last colour.

The hermit.—Is sometimes larger than the nun; the head, tail, and flight-feathers of the wings, for the most part preserve an uniformity of colour, either yellow, red, blue, or black; but all the rest of its body is generally white; so that the most material difference between it and the nun is, that the former has no hood on the back part of the head, and is frequently gravel-eyed.

The jacobine.—This is usually called, for shortness, the jack; it has a range of inverted feathers on the back part of the head, which turns toward the neck, like the cap or cowl of a monk, whence this bird derives its name of jacobine, or capper, as some call it; the religious of that order wearing cowls or caps, joined to their garments, for the purpose of covering their heads.

The ruff.—The ruff has a longer beak, and larger head; it is also rather a larger pigeon than the last; the irids of its eyes are in some of a gravel, in others of a pearl colour; the chain does not flow so near to the shoulders of its wings, though both the hood and chain are longer, but are nothing like so compact as the

PIGEON.

others, and are easily disturbed with every puff of wind; they likewise fall more backward from the head, in a rumpled discomposed form, and from this the pigeon receives its name.

The turbit.—This is a small pigeon, very little bigger than a jacobine: it has a round button head, and the shorter the beak is the better; it has a tuft of feathers growing from the breast, which opens and spreads both ways, sprouting out like the chitterlin of a shirt; this is called the purle; it has also a gullet which reaches from the back to the purle: this bird is admired according to the largeness of its purle.

The owl.—Is rather less than a jacobine, with a gravel eye, and a very short hooked beak, much resembling that of an owl, and from this the bird derives its name. The purle in this bird is rather larger, and opens and expands itself more like a rose than that of the turbit's; but in every other respect, both in shape, make, and plumage, this bird is so very like the turbit, the beak excepted, as to render any further description needless.

The capuchin.—A pigeon which has its name from an order of barehead monastics: it has a longer beak than the jack, and is somewhat larger in its body; it has no chain, but a very pretty hood, and is in plumage and other properties the same as the jack. Some fanciers positively affirm it to be a distinct species; others again as confidently affirm it to be a bastard breed, between a jacobine and some other pigeon; however it is beyond a doubt, that a jack and another pigeon will breed a bird so exactly similar to it, as will greatly embarrass the fanciers of this first persuasion to distinguish between it and what they term their separate species. Though all the pigeons of the toy kind have their respective admirers, the capuchin is but lightly esteemed by amateurs in general.

The finnikin.—In make, shape, and size, this differs very little from the common runt; the crown of its head is formed very like the head of a snake; it has a gravel eye, with a tuft of feathers growing on the back part of its crown, which falls down its neck, hanging like a horse's mane; it has a clean leg and foot, and its plumage is always blue or black-pied.

The turner.—Is in so many respects like the finnikin, that little more remains to be said about it: than to point out the difference between them it is not snake-headed, and the tuft on the back part of the crown is wanting; and when the wanton fit is on it and it plays to the female, it turns only one way, while the finnikin turns both.

The broad tail shaker.—This pigeon, especially when lustful, has a frequent tremulous motion, or shaking in the neck; which, joined to the breadth of its tail when spread, gives the bird the name of the broad-tail shaker.

It has a beautiful long taper neck, which it erects in a serpentine form, rather leaning towards its back, somewhat like that of the swan. Its beak is very short; it is exceedingly full breasted, and has a tail that is composed of a great number of feathers, very seldom less than four and twenty, but never exceeding six and thirty, which it spreads in a very striking manner, like the tail of a turkey-cock, and raises it up to such a degree, that the tail appears joined to the head.

The narrow tail shaker.—This is a bastard strain between the broad tail shaker and some other pigeon; it has a longer back and shorter neck

than that of the last-mentioned bird: it has also a less number of feathers in its tail, which it does not spread like the former, but lets them fall, as it were, double, the oneseide folding over the other, in the manner of a fan when three parts opened, and is apt to let it droop very much.

The barb.—This bird is rather larger than the jacobine; it has a short thick beak, like a bullfinch, encrusted with a small wattle, and a naked circle of a thick spongy red skin round its eyes, like that of the carrier; when the feathers of the pinion are inclinable to a dark colour, the irids are red, as is observable in some others of the pigeon tribe.

The mahomet.—Differs from the barb in nothing but the colour, which is of a fine white. In other respects it bears a strong resemblance.

The lace pigeon.—This is about the size of the common runt, and not unlike it in shape, but the colour of its plumage is white.

The frill back.—This is less than the common runt, though very much like it in shape. The plumage of this bird is also white.

The smiter.—This pigeon, in shape, make, and diversity of plumage, nearly resembles the tumbler, the size excepted, it being a much larger bird.

The Chinese pigeon.—This bird in size is rather less than the common swallow; the sides of the head are yellow, but the top and the space round the eye are of an ash colour; it has a blueish ash-coloured beak, and the irids of its eyes are a fine white.

Diet proper for pigeons.—The common dove-house pigeon, being removed as it were but one step from a state of nature, is hardy, and will seek its own food, living upon almost any grain; yet it is far different from the fancy-birds, who require some attention, and are much more delicate.

These pigeons should be indulged with such grains as wheat, barley, oats, peas, horsebeans, vetches, tares, rape, and canary, or hemp-seed. But of all grains old tares prove to be the best suited to their nature; new tares should be given very sparingly, especially to young pigeons, as they are very liable to give them a scouring, though old tares will have the same effect, if by any accident they have been mixed with salt, or damaged by sea-water; for though pigeons are very fond of salt, too much is pernicious.

Horsebeans are esteemed the best food next to tares, but the smaller these are the better: there is a French sort called small ticks, which make good food; but we would advise those who feed their pigeons with beans sometimes to mix a few vetches with them, and to have all the beans split.

Wheat, barley, oats, and peas, ought only to be given occasionally as a change of diet, since they are very subject to scour them. There is a mixed diet made of tares, beans, and peas, which is called Scotch meat, with which some fanciers feed their pigeons for cheapness, but care should be taken that the beans are not too large. Rape and canary, and hemp-seed, is a diet that pigeons are immoderately fond of; yet this, for many reasons, ought not to be employed as a constant diet.

Pigeons are protected by the legislature. By the 1 James, c. 27. whosoever shall shoot at, kill or destroy, any dove or pigeon, with any gun or bow, or take, kill, or destroy the same with setting-dogs or nets, or any snares, engines, or in-

struments whatsoever, shall, on being convicted, before two justices, by confession, or oath of two witnesses, be committed to gaol for three months, or pay for the use of the poor 20s. for every pigeon; or, after this commitment, become bound by recognizance, with two sureties, before two justices, in 20l. each, not to offend in like manner again.

And by the 2d Geo. 3. c. 29. any person who shall shoot at, or by any means kill or take, with a wilful intent to destroy, any pigeon, he shall on conviction thereof, by confession, or oath of one witness, before one justice, forfeit 20s. to the prosecutor; and if not immediately paid, such justice shall commit him to the house of correction, for any term not exceeding three months, nor less than one, unless the penalty be sooner paid. Persons who are convicted on this act shall not be convicted by any former act, and prosecutions on this act must be commenced within two months after the offence was committed.

These two abstracts are given to inform the keepers of pigeons of the laws in force to protect them; but more especially to remove the vulgar error so prevalent among the lower class of people, that pigeons are a nuisance, that they destroy a great deal of seed in the fields, grain in the rick-yards, and loosen the tiles on the tops of buildings; and that any person may shoot them, provided that he does not carry them away. The above acts are unrepealed, and in full force: consequently every offender is liable to the punishments therein specified. See COLUMBA.

PIGEON ISLAND, a small island, eight miles from the coast of Malabar, and 15 from the town of Onore. Lon. 74. 6 E. Lat. 14. 1 N.

PIGEON PEA, in botany. See **PITISUS**.

PIGGIN. s. A small wooden vessel.

PIGHT, old pret. and part. pass. of *pitch*. Pitched; placed; fixed; determined (*Shakespeare*).

PIGMENT. (*pigmentum*, from *pingo*, to paint.) This name is given by anatomists to a mucous substance found in the eye, which is of two kinds. The pigment of the iris is that which covers the anterior and posterior surface of the iris, and gives the beautiful variety of colour in the eyes. The pigment of the choroid membrane is a black or brownish mucus which covers the anterior surface of the choroid membrane, contiguous to the retina and the interior surface of the ciliary processes.

PIGMENTS, in the arts, are preparations in a solid form, chiefly employed by painters, for imitating particular colours, and imparting them to the surface of bodies. They are obtained from animal, vegetable, and mineral substances: the latter are the most durable. See COLOURS.

PIGMY, in mastiology. See **SIMIA**.

PI'GMY. s. (*pygmaeus*, Latin.) A small nation, fabled to be devoured by the cranes; thence any thing mean or inconsiderable (*Garth*).

PIGNORATION. s. (*pignora*, Lat.) The act of pledging.

PIG NUT. Earth nut. Ground nut. The bulbous root of the bunion bulbocastanum of Linnæus. Pignuts, so called because

the pig is very fond of them, and will dig with its snout to some depth for them, are of a dirty brown colour, a little bigger than a hazel-nut, and flavoured like the chesnut. They are said to possess a styptic quality, and are deemed serviceable in laxity of the kidneys.

PIGSNEY. s. (*piza*, Sax. a girl.) A word of endearment to a girl.

PIGWIDGEON. s. A cant word for any thing petty or small (*Claveland*).

PIKE, an offensive weapon, consisting of a shaft of wood, twelve or fourteen feet long, headed with a flat-pointed steel, called the spear. The pike was a long time in use among the infantry, to enable them to sustain the attack of the cavalry, but it is now taken from them, and the bayonet, which fixes on at the end of the carbine, is substituted in its place. Yet the pike still continues the weapon of the sergeants, who fight pike in hand, salute with the pike, &c.

PIKE, in ichthyology. See **ESOX**. The pike usually a still, shady, unfrequented water, and usually lies amongst or near weeds; such as flags, bulrushes, candocks, reeds, or in the green fog that sometimes covers standing waters, though he will sometimes shoot out into the clear stream.

Pike are angled for in various ways: the two following, denominated trolling, and snapping, are the most common.

Let your line be of green or sky-coloured silk, thirty yards in length, which will make it necessary to use the winch, with a swivel at the end.

The usual trolling hook for a living bait consists of two large hooks, with one common shank, made of one piece of wire, of about three-quarters of an inch long, placed back to back, so that the points may not stand in a right line, but incline so much inwards as that with the shank they may form an angle little less than equilateral. At the top of the shank is a loop left in the bending the wire, to make the hook double, through which is put a strong twisted brass wire of about six inches long: and to this is looped another such link, but not so loose that the hook and the lower link may have room to play: to the end of the line fasten a steel swivel.

But there is a sort of trolling-hook different from this, which is thought preferable, and will require another management; this consists of two single hooks tied back to back with a strong piece of gimp between the shanks; in the whipping the hooks and the gimp together, make a small loop, and take into it two links of chain of about an eighth of an inch in diameter; and into the lower link, by means of a small staple of wire, fasten near the greater end a bit of lead of a conical figure, and somewhat sharp at the point. These hooks are to be had at any fishing-tackle shops ready prepared.

This latter kind of hook is to be thus ordered: put the lead into the mouth of the bait-fish, and sew it up; the fish will live some time, and, though the weight of the lead will keep

P I K E.

his head down, he will swim with nearly the same pliancy as if at liberty.

But if you troll with a dead bait, as many do because a living bait makes too great a slaughter among the fishes, do it with a hook of the following contrivance.

Let the shank be about six inches long, and leaded from the middle as far as the bent of the hook, to which a piece of very strong gimp must be fastened by a staple, and two links of chain; the shank must be barbed like a dart, and the lead a quarter of an inch square; the barb of the shank must stand like the fluke of an anchor, placed in a contrary direction to that of the stock. Let the gimp be about a foot long, and to the end fix a swivel: to bait it, thrust the barb of the shank into the mouth of the bait-fish, and bring it out at the side near the tail: when the barb is thus brought through, it cannot return, and the fish will lie perfectly straight, a circumstance that renders the trouble of tying the tail unnecessary.

There is yet another sort of trolling-hook, which is the common hook, of which those already mentioned are improvements. This is a hook either single or double, with a long shank, leaded about three inches up the wire with a piece of lead about a quarter of an inch square at the greater or lower end; to the shank is fixed an armed wire about eight inches long. To bait this hook thrust your wire into the mouth of the fish, quite through his belly, and out at his tail, placing the wire so as that the point of the hook may be even with the belly of the bait-fish, and then tie the tail of the fish with strong thread to the wire: some fasten it with a needle and thread, which is a neat way.

Both with the troll and at the snap, cut away one of the fins of the bait-fish close to the gills, and another behind the vent on the contrary side, which will make it play the better.

The bait being thus fixed, is to be thrown into the water, and kept in constant motion, sometimes suffered to sink, then gradually raised; now drawn with the stream, and then against it, so as to counterfeit the motion of a small fish in swimming. If a pike be near, he mistakes the bait for a living fish, seizes it with prodigious greediness, goes off with it to his hold, and in about ten minutes pouches it. When he has thus swallowed the bait you will see the line move, which is the signal for striking him; do this with two strong jerks, and then play him.

The method of fishing with the snap is as follows:

Let the rod be twelve feet long, very strong and taper, with a strong loop at top to fasten your line to; your line must be about a foot shorter than the rod, and much stronger than the trolling line. This mode of fishing is pursued both with the live and the dead snap.

For the live snap there is no kind of hook so proper as the double-spring hook. To bait it, nothing more is necessary than to hang the bait-fish fast by the backfin to the middle-hook, where he will live a long time.

Of hooks for the dead snap there are many kinds: that prepared as follows is most esteem-

ed. Whip two hooks, of about three-eighths of an inch in the bent, to a piece of gimp in the manner directed for the trolling-hook. Then take a piece of lead of the same size and figure as directed for the trolling-hook above mentioned, and drill a hole through it from end to end; to bait it, take a long needle, or wire, enter it in at the side, about half an inch above the tail, and with it pass the gimp between the ribs and skin of the fish, bring it out at its mouth; then put the lead over the gimp, draw it down into the fish's throat and press his mouth close, and then, having a swivel to your line, hang on the gimp.

In throwing the bait observe the rules for trolling; but remember, that the more you keep it in motion, the nearer it resembles a living fish.

When you have a bite, strike immediately the contrary way to that in which the head of the pike lies, or in which he swims with the bait; if you cannot find which way his head lies, strike upright with two smart jerks, retreating as fast as you can, till you have brought him to a landing-place, and then do as before directed.

As the pike spawns in March, and before that month rivers are seldom in order for fishing, it will hardly be worth while to begin trolling till April; and after that time the weeds will be apt to be troublesome. But the prime month in the year for trolling is October, when the pikes are fattened by their summer's feed, the weeds are rotted, and by the falling of the waters the harbours of the fish are easily found.

Prefer to troll in clear, and not muddy, water, and in windy weather, if the wind be not easterly.

Some use in trolling and snapping two or more swivels to their line, by means of which the twisting of the line is prevented, the bait plays more freely, and, though dead, is made to appear as if alive; which, in rivers, is doubtless an excellent way: but those who like to fish in ponds or still waters will find very little occasion for more than one.

The pike is also to be caught with a minnow, for which method take the following directions:

Get a single hook, slender, and long in the shank; let it resemble the shape of a shepherd's crook; put lead upon it, as thick near the bent as will go into the minnow's mouth; place the point of the hook directly up the face of the fish; let the rod be as long as you can handsomely manage, with a line of the same length, cast up and down, and handle it as when you troll with any other bait: if when the pike has taken your bait, he run to the end of the line before he hath gorged it, do not strike, but hold still only, and he will return back and swallow it; with a troll there can be no better bait.

In landing a pike great caution is necessary, for his bite is esteemed venomous: the best and safest hold you can take of him is by the head, in doing which, place your thumb and finger in his eyes.

If you go any great distance from home, you will find it necessary to carry with you many more things than are here enumerated, most of which may be very well contained in a wicker pannier of about twelve inches wide, and eight high, and put into a hawking bag. The following is a list of the most material articles: a rod with a spare top, lines coiled up, and neatly laid round in flat boxes; spare links, single hairs, waxed thread, and silk; plummets of various sizes, floats of all kinds, and spare caps: worn bags and a gentle-box, hooks of all sizes, some whipped to single baits; shot, shoemaker's wax, in a very small gallipot covered with a bit of leather; a clearing ring, tied to about six yards of strong cord, the use of this is to disengage your hook when it has caught a weed, &c. in which case take off the butt of your rod and slip the ring over the remaining joints, and, holding it by the cord, let it gently fall; a landing net, the hoop whereof must be of iron, and made with joints to fold, and a socket to hold a staff. Take with you also such baits as you intend to use. And that you may keep your fish alive, be provided with a small hoop-net to draw close to the top, and never be without a sharp knife and a pair of scissors; and if you mean to use the artificial fly, have always your fly-hook with you.

And for the more convenient carriage of lines, links, single hairs, &c. take a piece of parchment or vellum, seven inches by ten; on the longer sides set off four inches, and then fold it cross-ways, so as to leave a slip of two inches, or thereabout; then take eight or ten pieces of parchment, of seven inches by four, put them into the parchment or vellum, so folded, and sew up the ends; then cut the flap rounding, and fold it down like a pocket-book, and bind the ends and round the flap with red tape.

And having several of these cases, you may fill them with lines, &c. proper for every kind of fishing; always remembering to put into each of them a gorgon, or small piece of cane, of five inches long, and a quarter of an inch wide, with a notch at each end; with this, when a fish has gorged your hook, you may, by putting it down his throat till you feel the hook (holding the line tight while you press it down), easily disengage it.

PIKED. *a.* (*pique*, French.) Sharp; acuminate; ending in a point (*Shakspeare*).

PIKEMAN. *s.* (*pike* and *man*.) A soldier armed with a pike (*Knolles*).

PIKESTAFF. *s.* (*pike* and *staff*.) The wooden pole of a pike (*Tatler*).

PILA, was a ball made in a different manner according to the different games in which it was to be used. Playing at ball was very common amongst the Romans of the first distinction, and was looked upon as a manly exercise, which contributed both to amusement and health. The pila was of four sorts: 1st, *follis* or balloon; 2d, *pila trigonalis*; 3d, *pila paganica*; 4th, *harpastum*. All these come under the general name of *pila*.

PILASTER, in architecture, a square column, sometimes insulated, but more frequent-

ly let within a wall, and only showing a fourth or fifth part of its thickness. See **ARCHITECTURE**.

PILATE (Pontius), a Roman governor of Judea. It was before him that our Saviour was brought, and condemned to death, though he asserted himself his innocence. Pilate was removed from Judæa by Tiberius for his cruelty, and sent an exile to Gaul, where he hanged himself, A. D. 37. The letter said to be written by him to Tiberius, giving an account of our Saviour and his miracles, is spurious.

PILATRE DU ROSIER (Francis), a native of Metz, who established a museum at Paris, and studied chemistry. On the discovery of balloons by Montgolfier, he first ventured to ascend the air in those frail vehicles. After various experiments, he formed the bold plan of passing over to England. He came to Boulogne, and on the 15th June, 1785, he, accompanied by his friend Romain, rose in a beautiful balloon before thousands of spectators, with the hopes of crossing the channel. Half an hour after, however, the machine caught fire, and the two unfortunate aeronauts were precipitated from a height of above 1500 feet to the ground, and dashed to pieces. They were buried in the village of Wimille, where a monument records their misfortune.

PILCHARD, in ichthyology. See **CLUPEA**.

PILCHER. *s.* (*pylece*, Saxon.) A furred gown or case; any thing lined with fur (*Hammer*).

PILE. *s.* (*pile*, Fr. *pyle*, Dutch.) 1. A strong piece of wood driven into the ground to make a firm foundation (*Knolles*). 2. A heap; an accumulation (*Shakspeare*). 3. Anything heaped together to be burned. 4. An edifice; a building (*Pope*). 5. (*pilus*, Latin.) A hair (*Shakspeare*). 6. Hairy surface; nap (*Grew*). 7. (*pilum*, Latin.) The head of an arrow.

To PILE. *v. a.* 1. To heap; to coacervate (*Shakspeare*). 2. To fill with something heaped (*Abbot*).

PILE, in botany, the cap of a fungus, expanding horizontally, and covering the fructifications.

PILE, in coinage, denotes a kind of punchon, which, in the old way of coining with the hammer, contained the arms, or other figure and inscription to be struck on the coin. Accordingly we still call the arms side of a piece of money the pile, and the head the cross, because in ancient coin a cross usually took the place of the head in ours: but some will have it called pile, from the impression of a church built on piles, struck on this side our ancient coins, and others will have it to come from *pile*, the old French word for a ship.

PILE, in heraldry, an ordinary in form of a wedge, contracting from the chief, and terminating in a point towards the bottom of the shield. The pile, like other ordinaries, is borne inverted, engrailed, &c. and issues indifferently from any point of the verge of an escutcheon.

PILE, in military affairs. Piles of shot or shells are generally formed in the king's magazines, in three different manners; the base

is either a triangular square, or a rectangle; and from thence the piles are called triangular, square, and oblong.

Rules for finding the Number of Shot in any Pile.

Triangular Pile. Multiply the number in the side of the base by the base $+ 1$, this product by the side $+ 2$, and divide by 6.

Square Pile. Multiply the bottom row by the bottom row $+ 1$, and this product by twice the bottom row $+ 2$, and divide by 6.

Rectangular Piles. Multiply the breadth of the base by itself $+ 1$, and this product by three times the difference between the length and breadth of the base, added to twice the breadth $+ 1$, and divide by 6.

Incomplete Piles. Incomplete piles being only frustrums, wanting a similar small pile on the top, compute first the whole pile as if complete, and also the small pile wanting at top; and then subtract the one number from the other.

PILE ENGINE, an engine constructed to facilitate the driving of piles, by means of the momentum of a heavy falling weight. The machines most used for this purpose are those invented by Bunce and Vauloué; for descriptions of which, see Gregory's *Mechanics*, vol. ii. and for scientific computations relative to the effects produced by pile-drivers, see Desaguliers's *Philosophy*, vol. i. *Philosophical Transactions*, new abt. vol. xiv. pa. 498; and Hutton's *Course of Mathematics*, vol. iii.

PILLEATED. *a.* (*pileus*, Lat.) Having the form of a cover or hat (*Woodward*).

PILER. *s.* (from *pile*.) He who accumulates.

PILES, in medicine. See **HEMORRHOIDS**.

PILES (Roger de), an ingenious painter, born at Clamecy, 1635. He visited several European courts, in the suite of the French ambassador, and in 1692 went to Holland as a secret negotiator, in the character of a picture virtuoso. His intrigues were discovered, and he was thrown into prison, from which the peace of Ryswick liberated him. In his confinement he wrote the lives of painters, and on his return to France received a pension. He died 1709, aged 74. He published besides a translation of Dufresnoy—an abridgement of anatomy accommodated to painting and sculpture—dissertations on the works of famous painters, &c.

PILEWORT, in botany. See **CHELEDONUM**.

To PILLFER. *v. a.* (*piller*, Fr.) To steal; to gain by petty robbery (*Bacon*).

To PILLFER. *v. n.* To practise petty theft (*Shakspeare*).

PILLFERER. *s.* (from *pilfer*.) One who steals petty things (*Atterbury*).

PILLFERINGLY. *ad.* With petty larceny; filchingly.

PILLFERY. *s.* (from *pilfer*.) Petty theft.

PILGRIM, one who travels through foreign countries to visit holy places, and to pay his devotion to the relics of dead saints. See

PILGRIMAGE. The word is formed from the Flemish *pelgrim*, or Italian *pelegrino*, which signifies the same; and those originally from the Latin *peregrinus*, a stranger or traveller.

To PILGRIM. *v. n.* (from the noun.) To wander; to ramble: not used (*Grew*).

PILGRIMAGE, a kind of religious discipline, which consists in taking a journey to some holy place in order to adore the relics of some deceased saint. Pilgrimages began to be made about the middle ages of the church; but they were most in vogue after the end of the 11th century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella, and Tours; but the greatest numbers now or recently resort to Loretto, in order to visit the chamber of the blessed Virgin, in which she was born, and brought up her son Jesus till he was 12 years of age. This chamber, it is pretended, was carried by angels into Dalmatia, about the year 1291, and afterwards in the same manner transported to Loretto, where a magnificent cathedral is built over it. In this chamber is the image of the blessed Virgin, almost covered with pearls and diamonds, and round the statue there is a kind of rainbow, formed of precious stones of various colours. Five hundred thousand pilgrims have sometimes resorted to this house in one year, in order to pay their devotions before this glorious image.

Several of the principal orders of knighthood were established in favour of pilgrims going to the Holy Land, to secure them from the violence and insults of the Saracens and Arabs, &c.

Such were the orders of the knights Templars, the knights Hospitalers, knights of Malta, &c.

The Mahometans are commanded in the Koran to perform a pilgrimage to Mecca; this is one of the capital points of their religion, and therefore a prodigious cavalcade of pilgrims annually go thither, in the company of those who are sent with the grand seignor's presents to the tomb of Mahomet.

Dr. Johnson, in his *Rasselas*, gives us some observations on pilgrimage, which are so much to the purpose, that we think we cannot do better than lay them before our readers. "Pilgrimage (said Imlac, into whose mouth the observations are put), like many other acts of piety, may be reasonable or superstitious according to the principles upon which it is performed. Long journeys in search of truth are not commanded. Truth, such as is necessary to the regulation of life, is always found where it is honestly sought: change of place is no natural cause of the increase of piety, for it inevitably produces dissipation of mind. Yet since men go every day to view the fields where great actions have been performed, and return with stronger impressions of the event, curiosity of the same kind may naturally dispose us to view that country whence our religion had its be-

ginning: and I believe no man surveys those awful scenes without some confirmation of holy resolutions. That the Supreme Being may be more easily propitiated in one place than in another, is the dream of idle superstition; but that some places may operate upon our own minds in an uncommon manner, is an opinion which hourly experience will justify. He who supposes that his vices may be more successfully combated in Palestine, will, perhaps, find himself mistaken; yet he may go thither without folly: he who thinks they will be more freely pardoned, dishonours at once his reason and religion."

PILI CONGENITI. The hairs of the head, eyebrows, and eyelids, are so termed, because they grow in *utero*.

PILI POSTGENITI. The hair which grows from the surface of the body after birth is so termed, in contradiction to that which appears before birth; as the hair of the head, eyebrows, and eyelids.

PILL. In pharmacy, a particular mode of compounding certain preparations; for which see **PILULÆ**.

To PILL. v. a. (*piller*, French.) 1. To rob; to plunder (*Shakspeare*). 2. For peel: to strip off the bark (*Genesis*).

To PILL. v. n. To be stript away; to come off in flakes or scoriae: properly *peel* (*Tobit*).

PILLAGE. s. (*pillage*, French.) 1. Plunder; something got by pilling (*Shakspeare*). 2. The act of plundering (*Shakspeare*).

To PILLAGE. v. a. (from the noun.) To plunder; to spoil (*Arbutnot*).

PILLAGER. s. (from *pillage*.) A plunderer; a spoiler (*Chapman*).

PILLAR. s. (*pilier*, Fr. *pilar*, Spanish.) 1. A column (*Wotton*). 2. A supporter; a maintainer (*Shakspeare*).

PILLAR, in the manage. Most of the great riding-schools have pillars fixed in the middle of the manage ground, to point out the center; but all manages in general have, upon the side or circumference, other pillars placed, two and two, at certain distances, whence these are called the two pillars, to distinguish them from that of the center.

When they speak of the former, they call it working round the pillar; and when they refer to the other two, they call it working between the two pillars. The pillar of the center serves to regulate and adjust the extent of ground, to the end that the manage upon volts may be performed with method and justness, and that they may work in a square by rule and measure, upon four lines of the volt, which ought to be imagined at an equal distance from the center. It serves likewise to break unruly high-mettled horses, without endangering the rider, the horse being tied to a long rope, one end of which is made fast to a pillar, and managed by a man placed by the pillar, which keeps the horse in subjection, and hinders him from flying out.

PILLARED. a. (from *pillar*.) 1. Supported by columns (*Milton*). 2. Having the form of a column (*Thomson*).

PILLION. s. (from *pillow*.) 1. A soft saddle set behind a horseman for a woman to sit on (*Swift*). 2. A pad; a pannel; a low saddle (*Spenser*). 3. The pad of the saddle that touches the horse.

PILLORY (*collistrigium, collum stringens; pilloria*, from the French *pilleur*, i. e. *depeculator*, or *pelori*; derived from the Greek *πύλη, janua*, a door, because one standing on the pillory puts his head as it were through a door, and *ὀραω, video*), is an engine made of wood to punish offenders, by exposing them to public view, and rendering them infamous. There is a statute of the pillory, 51 Hen. III. And by statute it is appointed for bakers, forestallers, and those who use false weights, perjury, forgery, &c. 3 Inst. 219. Lords of leets are to have a pillory and tumbrel, or it will be the cause of forfeiture of the leet; and a village may be bound by prescription to provide a pillory, &c. 2 Hawk. P. C. 73.

To P'LLORY. v. a. (*pillorier*, French.) To punish with the pillory (*Government of the Tongue*).

P'LLOW. s. (*pylle*, Sax.; *pulewe*, Dutch.) A bag of down or feathers laid under the head to sleep on (*Donne*).

To P'LLOW. v. a. To rest any thing on a pillow (*Milton*).

P'LLOWBEER. P'LLOWCASE. s. The cover of a pillow (*Swift*).

PILOBOLUS, in botany, a genus of the class cryptogamia, order fungi. Fungus on a capillary stem, inflated, and watry at top, with an hæmispheerical head elastically ejecting the seeds. Three species; mushrooms of our own country.

PILOCARPUS, in botany, a genus of the class pentandria, order monogynia. Calyx five-leaved; corol five-petalled; stamens inserted under the germ; capsules five, united at the base, one-seeded, elastic; seeds axillate. One species; a Montserrat shrub, with pendulous branches, and solitary racemes from their tops.

PILOSELLA. (from *pilus*, hair, because its leaves are hairy.) *Auricula muris*. *Myosotis*. Mouse ear. This common plant, *Hieracium pilocella* of Linnæus, contains a bitter lactescent juice, which has a slight degree of adstringency. The roots are more powerful than the leaves. They are very seldom used in this country.

PILOSITY. s. (from *pilosus*, Lat.) Hairiness (*Bacon*).

PILOT, a person employed to conduct ships over bars and sands, or through intricate channels, into a road or harbour. Pilots are no constant and standing officers aboard our vessels, but are called in occasionally, on coasts or shores unknown to the master, and having piloted in the vessel, they return to the shore where they reside.

Every respect and attention are paid to pilots on board his Majesty's ships: they are likewise well accommodated, and when conducting a ship have the sole command of it, and may give orders for steering, setting, trimming,

&c. The captain is to see that all the officers and men obey his orders.

Pilots taking upon them to conduct ships up the Thames are to be examined and approved by the master and wardens of the Trinity-house at Deptford, or shall be liable to forfeit 10*l.* for the first offence, and 20*l.* for the second, &c. and the like penalty, if they act without licence from the said master and wardens; and if by their negligence they lose a ship, they shall be for ever disabled. 3 Geo. I. and 5 Geo. II. c. 20. 30.

To *PILOT. v. a.* (from the noun.) To steer; to direct in the course.

PILOT FISH, in ichthyology. See *GASTROSTEUS*.

PILOTAGE. s. (*pilotage*, Fr. from *pilot*.) 1. Pilot's skill; knowledge of coasts (*Ral.*). 2. A pilot's hire (*Ainsworth*).

PILOUS LEAF, in botany. A hairy leaf. Having the surface covered with long distinct hairs: as in *cortusa*, *juncus pilosus sylvaticus*, *campestris*.—*Pilosus seed*. A hairy seed. As in *centaurea* and *tragopogon*.—*Pilosus receptacle*. A hairy receptacle. Having hairs between the florets.

PILPAY, an ancient Bramin fabulist, whose fables, written above 2000 years ago, were translated into French from the Greek or Persian, by Galland, 1755. It is supposed that he was governor of Indostan, and counsellor to an Indian king.

PILULÆ, in pharmacy, pills: small balls or masses of pharmaceutic materials, or the general mass itself from which the balls are formed. The different preparations in different pharmacopœias existing under this name are very numerous. The following are some of the chief.

PILULÆ ALOES COMPOSITÆ. From fifteen to twenty-five grains prove moderately purgative and stomachic.

PILULÆ ALOES CUM MYRRHA. From ten grains to a scruple of this pill, substituted for the *pilula rufi*, prove stomachic and laxative, and are calculated for delicate females, especially where there is uterine obstruction.

P. CUPRI. An excellent tonic and diaphoretic pill, which may be given with advantage in dropsical diseases, where tonics and diuretics are indicated.

P. GALBANI COMPOSITÆ. A stimulating antispasmodic and emmenagogue. From a scruple to half a drachm may be given three times a day in nervous disorders of the stomach and intestines, in hysterical affections and hypochondriasis.

P. HYDRARGYRI. An alterative and anti-venereal pill, which mostly acts on the bowels if given in sufficient quantity to attempt the removal of the venereal disease, and therefore requires the addition of opium. Joined with the squill pill, it forms an excellent expectorant and alterative, calculated to assist the removal of dropsical diseases of the chest, and asthmas attended with visceral obstruction.

P. HYDRARGYRI SUBMURIATIS, SIVE, CALOMELANOS COMPOSITÆ. This is intended as a substitute for the famed Plummer's pill. It is exhibited as an alterative in a variety of diseases, especially cutaneous eruptions, pains of the venereal or rheumatic kind, cancerous and scirrhus affections, and chronic ophthalmia.

P. SAPONIS CUM OPIO. Five grains of this mass contain one of opium.

P. RHEI COMPOSITÆ. Laxative and stomachic, in the dose of from fifteen grains to half a drachm.

P. SCILLÆ. An attenuant, expectorant, and diuretic pill, mostly administered in the cure of asthma and dropsy.

PILULARIA. Pill-wort. In botany, a genus of the class cryptogamia, order musci. Common receptacle globular, villous, four-celled, four-valved, filled with numerous anthers and many globular germs beneath them. One species only, *P. globulifera*, common to our own pastures.

PILUM, a missive weapon used by the Roman soldiers, and in a charge darted upon the enemy. Its point, we are told by Polybius, was so long and small, that after the first discharge it was generally so bent as to be rendered useless. The legionary soldiers made use of the pilum, and each man carried two.

PILUMNUS. See *PICUMNUS*.

PILUS. (*πῖλος*; wool carded.) In anatomy, the short hair which is found all over the body. See *CAPILLUS*.

PILUS, in botany. *Ductus excretorius plantæ setaceous*. An excretory duct of a plant, in shape of a bristle.—This, however, appears to be an improper explanation of hair by bristle, inasmuch as a bristle is only a stiff hair.—It is a sort of pubescence.

PIMELIA, in botany, a genus of the class diandria, order monogynia. Calyxless; corol four-cleft, stamens inserted into the throat; nut covered with a bark, one-celled. Four species: all natives of Australasia or New Zealand.

PIMELIA, in zoology, a genus of the class insecta, order coleoptera. Antennas filiform; feelers four; thorax plano-convex, margined; head exserted; shells rather rigid; wings usually none. A hundred and seventeen species, scattered over the globe, five or six common to our own country: found in dry deserts, and gardens, and sometimes in houses; several species in filth and manure. The genus is thus subdivided.

A. Antennas moniliform at the tip.

a. Feelers filiform; comprising the *pimela* tribe of Fabricius.

6. Feelers clavate; the blaps of Fabricius.

B. Antennas entirely filiform.

a. Feelers four, filiform. The *sepidium* of Fabricius.

6. Fore-feelers hatchet-shaped, hind-ones clavate. The *helops* of Fabricius.

The following may serve as specimens:

1. *P. sulcata*. Shells mucronate, grooved;

the grooves eight or nine, and the shells united. Inhabits the East; and is sold in Turkey as a specific against pains in the ears, and the bite of scorpions. It is also boiled with butter and eaten by the Turkish ladies for the purpose of making them grow fat.

2. *P. mortisaga*. Black; shells mucronate, subpunctured. Inhabits Europe, and found in our own country. This inoffensive animal is regarded as a presage of the death of some one in a family, by the common people of Sweden, if seen crawling about the house.

PIMENTA. See PIMENTO.

PIMENTO. (from *Pamienta*, Sp. pepper.) Jamaica pepper, or allspice. *Amomum pimenta*. *Myrtus pimenta* of Linnéus. *Myrtus floribus trichotomo-paniculatis, foliis oblongo-lanceolatis*, Hort. Kew. C. O. Icosandria, monogynia. This spice, which was first brought over for dietetic uses, has been long employed in the shops as a succedaneum to the more costly oriental aromatics: it is moderately warm, of an agreeable flavour, somewhat resembling that of a mixture of cloves, cinnamon, and nutmegs. Both pharmacopœias direct an aqueous and spirituous distillation to be made from these berries; and the Edinburgh College orders also the *oleum essentielle piperis Jamaicaensis*.

PIMP. *s.* (*pinge*, Fr. *Skinner*.) One who provides gratifications for the lust of others; a procurer; a pander (*Addison*).

To PIMP. *v. a.* (from the noun.) To provide gratifications for the lust of others; to pander; to procure (*Swift*).

PIMPERNEL, in botany. See ANAGALLIS.

PIMPINELLA. Barnet-saxifrage. In botany, a genus of the class pentandria, order digynia. Fruit ovate-oblong, striate; petals inflexed; stigmas subglobular. Nine species, south of Europe, Egypt, the Cape; three common to the mountains, dry soils, or hedges of our own country. The two following are chiefly worth noticing.

1. *P. magna*. Greater saxifrage. Leaves pinnate, all the leaflets ovate, the terminal one three-lobed. Two other varieties of it; all found in our hedges.

2. *P. anisum*. Anise. Leaves trifid and cut; an annual, originally of Egypt; but now largely grown in Spain and Malta, from both which places the market of this country is supplied. The seeds of both these, but especially of the latter, are employed as carminatives in medicine: for the pharmacœutic properties, see ANISUM.

PIMPINELLA ITALICA. The root which bears this name in some pharmacopœias is that of the *sanguisorba officinalis* of Linnéus. It is now fallen into disuse.

PIMPING. *a.* (*pimple mensch*, a weak man, Dutch.) Little; petty (*Skinner*).

PIMPLA, a mountain of Macedonia, on the confines of Thessaly, near Olympus, sacred to the Muses, who on that account are often called *Pimpleæ* and *Pimpleades*.

PIMPLE. *s.* (*pompette*, Fr.) A small red pustule (*Addison*).

PIMPLED. *a.* (from *pimple*.) Having red pustules; full of pimples.

PIN. *s.* (*espingle*, French.) 1. A short wire with a sharp point and round head, used by women to fasten their clothes (*Pope*). 2. Any thing inconsiderable or of little value (*Spenser*). 3. Any thing driven to hold parts together; a peg; a bolt (*Milton*). 4. A slender thing fixed in another body. 5. That which locks the wheel to the axle. 6. The central part (*Sh.*). 7. The pegs by which musicians intend or relax their strings. 8. A note; a strain (*L'Es-trange*). 9. A horny induration of the membranes of the eye (*Shakspeare*). 10. A cylindrical roller made of wood, with which pastry is wrought (*Corbet*). 11. A noxious humour in a hawk's foot.

To PIN. *v. a.* (from the noun.) 1. To fasten with pins (*Pope*). 2. To fasten; to make fast (*Shakspeare*). 3. To join; to fix; to fasten (*Digby*). 4. (pinban, Sax.) To shut up; to enclose; to confine, as in pinfold (*Hooker*).

PIN, according to the first of the above acceptations, though an apparently insignificant instrument, is an important article in commerce. The art of making pins of brass wire was not known in England before the year 1543: prior to that period they were made of ivory, bone, or box. In the year 1543, by statute 34 and 35 of Henry VIII. cap. vi. it was enacted, "that no person shall put to sale any pinnes but only such as shall be double-headed, and have the heads soldered fast to the shank of the pins, well smoothed, the shank well shapen, the points well and round filed, cauted, and sharpened." From the above extract it should appear that the art of pin-making was but of late invention, probably introduced from France; and that our manufactories since that period have wonderfully improved.

The pin manufactory was introduced into Gloucester in 1626 by John Tilsby: there are now in Gloucester nine distinct pin manufactories, which employ together at least 1500 persons.

Though pins are of apparently simple construction, their manufacture, however, is not a little curious and complex. We have traced with much pleasure the whole process in the manufactories at Gloucester, and observed that the article, small as it is, passes through 25 hands from its first state of rough wire to its being stuck in paper for sale. The following may suffice for a general sketch of the method.

When the brass wire, of which the pins are formed, is first received at the manufactory, it is generally too thick for the purpose of being cut into pins. The first operation therefore is that of winding it off from one wheel to another with great velocity, and causing it to pass between the two, through a circle in a piece of iron of smaller diameter: the wire being thus reduced to its proper dimensions, is straight-

P I N

ened by drawing it between iron pins, fixed in a board in a zigzag manner, but so as to leave a straight line between them: afterwards it is cut into lengths of three or four yards, and then into smaller ones, every length being sufficient to make six pins; each end of these is ground to a point, which is commonly performed by boys, who sit each with two small grinding-stones before him, turned by a wheel. Taking up a handful, he applies the ends to the coarsest of the two stones, being careful at the same time to keep each piece moving round between his fingers, so that the points may not become flat: he then gives them a smoother and sharper point, by applying them to the other stone, and by that means a lad of twelve or fourteen years of age is enabled to point about 16,000 pins in an hour. When the wire is thus pointed, a pin is taken off from each end, and this is repeated till it is cut into six pieces. The next operation is that of forming the heads, or, as they term it, head-spinning; which is done by means of a spinning-wheel, one piece of wire being thus with astonishing rapidity wound round another, and the interior one being drawn out leaves a hollow tube between the circumvolutions: it is then cut with shears, every two circumvolutions or turns of the wire forming one head: these are softened by throwing them into iron pans, and placing them in a furnace till they are red-hot. As soon as they are cold, they are distributed to children, who sit with anvils and hammers before them, which they work with their feet, by means of a lathe; and taking up one of the lengths, they thrust the blunt end into a quantity of the heads which lie before them; and catching one at the extremity, they apply them immediately to the anvil and hammer; and by a motion or two of the foot, the point and the head are fixed together in much less time than it can be described, and with a dexterity only to be acquired by practice; the spectator being in continual apprehension for the safety of their fingers' ends. The pin is now finished as to its form, but still it is merely brass; it is therefore thrown into a copper, containing a solution of tin and the leys of wine. Here it remains for some time; and when taken out assumes a white, though dull, appearance: in order therefore to give a polish, it is put into a tub containing a quantity of bran, which is set in motion by turning a shaft that runs through its centre; and thus by means of friction it becomes perfectly bright. The pin being complete, nothing remains but to separate from the bran; which is performed by a mode exactly similar to the winnowing of corn, the bran flying off, and leaving the pin behind fit for immediate sale. There is in many respects a considerable resemblance between the manufactory of pins and that of needles. See **NEEDLE**.

PINASTELLUM. (*pinastellum*, from *pinus*, the pine-tree; so called because its leaves resemble those of the pine-tree.) Hog's fennel. See **PEUCEDANUM**.

P I N

PINASTER, in botany. See **PINUS**.

PIN PILLOW, in botany. See **CACTUS**.

PINCASE. *s.* (*pin and case*.) A pincushion, or small box for pins.

PINCERS. *s.* (*pincette*, French.) 1. An instrument by which nails are drawn, or any thing is griped, which requires to be held hard (*Spenser*). 2. The claw of an animal (*Addison*).

To PINCH. *v. a.* (*pincer*, French.) 1. To squeeze between the fingers, or with the teeth (*Shakspeare*). 2. To hold hard with an instrument. 3. To squeeze the flesh till it is pained or livid (*Shakspeare*). 4. To press between hard bodies. 5. To gall; to fret (*Shakspeare*). 6. To gripe; to oppress; to straiten (*Raleigh*). 7. To distress; to pain (*Thomson*). 8. To press; to drive to difficulties (*Watts*). 9. To try thoroughly; to force out what is contained within (*Collier*).

To PINCH. *v. n.* 1. To act with force, so as to be felt; to bear hard upon; to be puzzling (*Dryden*). 2. To spare; to be frugal (*Dryd.*).

PINCH. *s.* (*pinçon*, Fr. from the verb.) 1. A painful squeeze with the fingers (*Dryden*). 2. A gripe; a pain given (*Shakspeare*). 3. Oppression; distress inflicted (*L'Estrange*). 4. Difficulty; time of distress (*L'Estrange*).

PINCHFAST. **PINCHPENNY.** *s.* (*pinch, fist, and penny*.) A miser (*Ainsworth*).

PINCHBECK, a compound metal. See **ZINCUM**.

PINCUSHION. *s.* (*pin and cushion*.) A small bag stuffed with bran or wool on which pins are stuck (*Addison*).

PINDAR, a celebrated lyric poet, of Thebes. He was trained from his earliest years to the study of music and poetry, and was taught how to compose verses with elegance by Myrtis and Corinna. When young, it is said that a swarm of bees settled on his lips, and there left some honey-combs as he reposed on the grass. This was explained as a prognostic of his future celebrity. In the public assemblies of Greece, where females were not permitted to contend, Pindar was rewarded with the prize, in preference to every other competitor. His hymns and pæans, composed on the conquerors at Olympia, &c. were repeated before the most crowded assemblies in the temples of Greece. It is said that Pindar died suddenly at the public gymnasium, at the advanced age of 86, B. C. 435, and that he was honoured with every mark of respect even to adoration. When the Lacedæmonians took Thebes, they spared the house of Pindar; and Alexander the Great did the same thing.

The fragments of Pindar collected from the ancients are arranged under the following heads, according to their subject, style of composition, and the musical modes to which they were adapted; *Scolia*, *Parthenia*, the distinguishing characters of which are obscure; *Threni*, in which the genius of Pindar was regarded by the ancients as inferior to that of Simonides; *Hyporchemata*, poems accompanied by dances, and chiefly devoted to the honour of Apollo;

Prosodia, Hymns, Pæans Dithyrambi. A considerable and remarkable fragment of a poem on an eclipse of the sun is preserved by Dionysius of Halicarnassus, in which the poet prays that the baneful influence of this prodigy may be averted from Thebes, whatever be the calamity which it forebodes, whether war, destruction to the produce of the earth, violent storms of snow, sedition, inroads of the sea, frost, a summer of incessant rain, or a deluge which should again sweep away the inhabitants of the earth.

The only remaining works of Pindar are forty-five odes, written in praise of the victors at the Olympic, Pythian, Nemean, and Isthmian games. The subjects, it must be allowed, are as unpromising as those of a modern laureat. Accordingly Pindar commonly treats his hero with very little ceremony, and bestowing on him a few lines of praise, and sometimes of advice, at the beginning and end of his ode, he usually employs the intermediate space in relating some fable of mythology, which may possess a relation more or less direct to the subject of his celebration. Thus in the longest of his remaining works, the fourth Pythian ode, addressed to Arcesilaus, prince of Cyrene, who had gained the victory in a chariot race at the Pythian games, in the second sentence he digresses to the colonization of Cyrene from Thera, and thence to the Argonautic expedition, in which that event was predicted, and the pledge of its accomplishment received. This furnishes Pindar with what he deems the proper subject of an ode, and he relates at length in a lyric style the chief events of the Argonautic expedition. He concludes with some sentences of advice, couched in elegant language, adapted to the circumstances of Arcesilaus and Cyrene; and intercedes in a delicate and respectful manner in favour of Damophilus, a Cyrenean exile, whom the poet had lately met at Thebes. The odes of Pindar are written in the boldest style of lyric poetry. It follows, therefore, that they abound in rapid and sudden transitions, and daring metaphors. In almost every ode his digressions are as free as in the single instance which has been cited. A few specimens will shew the license of his metaphors. *Ætna* is described as "the nurse of snow through the entire year." Tacitus, indeed, in prose employs an expression scarcely less bold, when he speaks of a mountain as "faithful to the snows." In the same ode from which the former expression is taken, he advises Hiero to "rule his people with a just helm, and to forge his tongue on the anvil of truth." This poet is universally admired, for his energy and magnificence of style, harmony of numbers, and elegance of diction.

Pindar was first printed by Aldus, with Calimachus, *Dionysius des itu orbis*, and *Lycophron*. Venet. 1513, 8vo.

The edition of Calliægues (Roma, 1515, 4to.) is more valued than the preceding. It contains the scholia, and is the chief basis of subsequent editions.

Cratander's edition, Basil, 1526, 8vo. taken from the former, is regarded as correct and valuable.

A splendid edition was published at Paris by Morel, 1558, 4to.

Several small editions were published by Henry and Paul Stephens, with the fragments of other lyric poets.

Erasmus Schmidt published Pindar, Witteberg, 1616, 4to. Schmidt was a man of real learning, and has perhaps done more for the illustration of Pindar than any other individual, though his learning partakes of the diffuseness, and his illustrations of the rhetorical formality, of his age.

An edition was published (Salmurii, 1620, 4to.) by J. Benedictus, a well-known scholar, and Greek professor at Saumur. It contains much useful illustration of the difficulties of the poet.

The Oxford edition of 1697, fol. by West and Welsted, is splendid and scarce. They have chiefly followed Schmidt. The edition is respectable, but the good intentions of the editors are valued rather more highly than their learning or sagacity.

Heyne's two editions of Pindar (Gott. 1773, 4to. 2 vols.; 1798, 8vo. 3 vols.) are very valuable. The latter is much the more ample.

Nearly a fourth of Pindar's odes were translated into English by Mr. West: the translation has been recently completed by an unknown hand, and the whole published in 4to. by Mr. Lee, in 1810. There is also a very respectable translation, by the rev. Mr. Girdlestone of Beccles.

PINDARIC ODE, an ode formed in imitation of Pindar.

PINDUS, a mountain, or rather a chain of mountains, between Thessaly, Macedonia, and Epirus. It was greatly celebrated as being sacred to the Muses and to Apollo.

PINDUST. *s. (pin and dust.)* Particles of metal made by pointing pins (*Digby*).

PINE, or **PINE-TREE**. See **PINUS**.

PINE-SCREW. See **PANDANUS**.

PINE-APPLE. See **BROMELIA**.

PINE-THISTLE. See **CARLINA GUMMIFERA**.

To PINE. v. n. (pinjan, Sax. pijnen, Dut.)
1. To languish; to wear away with any kind of misery (*Spenser*). 2. To languish with desire (*Shakspeare*).

To PINE. v. a. 1. To wear out; to make to languish (Shakspeare). 2. To grieve for; to bemoan in silence (Milton).

PINEA. (*pineæ*.) The stone pine. The young and fresh fruit of this plant, *pinus pinea* of Linnæus, are eaten in some countries in the same manner as almonds here, either alone or mixed with sugar. They are nutritive, demulcent, and laxative.

PINEAL GLAND. (called *pineal* from *pineæ*, a pine-apple, from its supposed resemblance to that fruit). *Glandula pinealis*. *Cornarium*. In anatomy, a small heart-like substance, about the size of a pea, situated imme-

diately over the corpora quadrigemina, and hanging from the thalami nervorum opticorum by two crura or peduncles. Its use is not known. It was formerly supposed to be the seat of the soul.

PINEAU (Gabriel du), of Angers, was called to the bar, and became so respectable, that he was confidently consulted in all affairs of moment, and was made master of requests by Mary de Medicis, and by her son Lewis XIII. mayor and captain general of the town of Angers. He acquired the appellation of father of the people. He died 1644, aged 71. He was author of Latin notes on the canon law in opposition to Du Moulin—commentaries, observations, &c. on custom and law, with dissertations, &c. 2 vols. fol.

PINEDA (John), a jesuit, of Seville, skilled in oriental literature. He died 1637. He wrote commentaries on Job, 2 vols. fol.—and also on Ecclesiastes—a learned work de rebus Solomonis, fol.—an universal history of the church, in Spanish, 4 vols. fol. &c.

PINELLI (John Vincent), born at Naples in 1553, was celebrated for the vast library he formed. His capacious mind embraced antiquity, natural history, medals, and every other science. He died in 1601. His library was greatly enlarged by his descendants, and was purchased by Mr. Robson, a London bookseller, by whom they were sold by auction in 1790.

PINES (Isle of), an island in the S. Pacific ocean, off the S. end of New Caledonia, 14 miles in length. It is quite a pointed hill, sloping toward the extremities, which are very low; and on the low land are many tall pine trees. Lon. 167. 38 E. Lat. 22. 38 S.

PINEUS PURGANS. See **RICINUS MAJOR.**

PINFEATHERED. *a.* (*pin* and *feather.*) Not fledged; having the feathers yet only beginning to shoot (*Dryden*).

PINFOLD. *s.* (*pin* and *fold*.) A place in which beasts are confined.

PINGLE. *s.* A small close; an enclosure.

PINGRE (Alexander Guy), a celebrated French scholar, born in 1709. He was a strenuous supporter of the liberties of the Gallican church against the bishops; so that in the space of four years, he received five lettres de cachet. He next applied himself to astronomy, and published A calculation of an eclipse of the moon on the 23d of December, 1749. The academy of sciences, in 1760, appointed him to observe the transit of Venus. Pingré calculated the eclipses of a thousand years before the vulgar æra. He was elected geographical astronomer in the room of De Lisle; and translated that difficult work, Manilius's poetical treatise on astronomy.

In the year 1784 he published *Cometographie*, in 2 vols. 4to. containing a history of all the methods employed to determine the elements of comets, and an extensive table of those elements. The latter part of his life he

dedicated to botany with considerable success. He died in 1796. Interesting memoirs of this ingenious philosopher are given in the *Monthly Magazine*, vol. ii. pa. 671.

PING-LIANG, a city of China, of the first rank, in the province of Chen-si; seated on the river Kin-ho, 550 miles S.W. of Peking. Lon. 106. 25 E. Lat. 35. 35 N.

PINGUEDO. (from *pinguis*, fat.) Fat. See **FAT.**

PINGUICULA. Butterwort. Yorkshire sanicle. In botany, a genus of the class dianthia, order monogynia: corol ringent, spurred; calyx two-lipped, five-cleft; capsule one-celled. Five species: two common to the bogs of our own country, the rest to the continent of Europe. Those of our own country have pale red, purple, or deep violet flowers, hairy within. The Swedes and Laplanders, among whom also both these species grow wild, employ the leaves to give consistency to their milk, which being passed through them in a strainer acquires the thickness of butter, the serum being at the same time prevented from separation. Cows, sheep, goats, horses, and swine, equally refuse the leaves; and there is a vulgar but erroneous opinion that when eaten accidentally by sheep they produce the disease called the rot. The remarkable unctuousity of this plant has caused it to be applied to chaps, and as a pomatum to the hair. Decoctions of the leaves in broths are used by the common people in Wales as a cathartic.

PINGUID. *a.* (*pinguis*, Lat.) Fat; unctuous (*Mortimer*).

PINGUIN, in botany. See **BROMELIA.**
PINGUIN PINGUIN. In ornithology. See **APTENODYTES.**

PINHEL, a strong town of Portugal, in Beira, capital of a territory of the same name. It is seated on the Coa, 28 miles N. by W. of Guarda. Lon. 6. 40 W. Lat. 40. 46 N.

PINHOLE. *s.* (*pin* and *hole.*) A small hole, such as is made by the perforation of a pin (*Wiseman*).

PINHONES INDICI. In botany. See **RICINUS MAJOR.**

PINION. *s.* (*pignon*, French.) 1. The joint of the wing remotest from the body. 2. A feather or quill of the wing (*Shakspeare*). 3. Wing (*Swift*). 4. The tooth of a smaller wheel, answering to that of a larger. 5. Fetters for the arms (*Ainsworth*).

To PINION. v. a. (from the noun.) 1. To bind the wings (*Bacon*). 2. To confine by binding the wings. 3. To bind the arm to the body (*Dryden*). 4. To confine by binding the elbows to the sides (*Dryden*). 5. To shackle; to bind (*Herbert*). 6. To bind to: not proper (*Pope*).

PINK, a name given to a ship with a very narrow stern; whence all vessels, however small, whose sterns are fashioned in this manner, are called pink sterned.

PINK, in botany. See **DIANTHUS.**

PINK (Indian), in botany. See **DIANTHUS.**

P I N

PINK (Mule), in botany. See **DIANTHUS**.

PINK (Sea), in botany. See **STATICE**.

PINK (Dutch), is a pigment formed of chalk, coloured with the tinging particles of French berries, or other vegetables. It is principally used for coarser purposes in water. It may be made by boiling one pound of French berries and four ounces of powdered turmeric root in a gallon of water for two hours, and then straining off the tincture through flannel, and boiling it again with an ounce of alum, till it be evaporated to one quart. Prepare in the mean time four pounds of chalk, by washing it over, and afterwards drying it; and mix the chalk with the tincture, by grinding them together, and then dry it on boards. It is sometimes prepared in the same manner with starch and white lead. Its goodness consists in its being of a full gold-coloured yellow, and very bright.

PINK (English), is only a lighter and coarser kind of Dutch pink; and may be prepared in the same manner, the quantity of chalk being increased in proportion, as it is intended to be inferior to the Dutch.

There are also other kinds of pink, as brown pink, rose pink, &c. which need not be described here.

To **PINK**. *v. n.* (from *pink*, Dutch, an eye.) To work in eyelet holes; to pierce in small holes (*Prior*).

To **PINK**. *v. n.* (*pinken*, Dutch.) To wink with the eyes (*L'Estrange*).

PINMAKER. *s.* (*pin* and *make*.) He who makes pins.

PINMONEY. *s.* (*pin* and *money*.) Money allowed to a wife for her private expences without account (*Addison*).

PINNA. Nacre. In zoology, a genus of the class vermes, order testacea. Animal a limax; shell bivalve, fragile, upright, gaping at one end, and furnished with a byssus or beard; hinge without teeth, the valves united into one. The inhabitants of these shells produce a large quantity of fine strong byssus, which by the Italians is woven into a sort of silk; the shells are generally found standing erect in the smoother waters of bays, with the larger end a little open; the animals or fishes of many are accounted a rich food. Eighteen species, scattered through the seas of the globe, of which only one is found on our own coast, *P. muricata*, a striate shell with concave, ovate, acute scales: from three to nine inches long, and from one to three broad; thin, brittle, pellucid, horny; the outside with longitudinal ribs, rough, with rows of small prickles. See *Nat. Hist. Pl. CLXIV*.

PINNA. The large feather of a bird's wing; or a fin in fishes: applied in botany to the leaflet of some compound leaves.

A subdivision of the pinna is called *pinnula*, or *pinnule*.

PINNACE. *s.* (*pinnasse*, Fr. *pinnacia*, Ital.) A boat belonging to a ship of war. It seems formerly to have signified rather a small sloop or bark attending a larger ship (*Raleigh*).

P I N

PINNACLE. *s.* (*pinnacle*, Fr. *pinna*, Lat.) 1. A turret or elevation above the rest of the building (*Clarendon*). 2. A high spiring point (*Cowley*).

PINNATE LEAF. Cum petiolus simplex lateribus adnectit foliola plura. A species of compound leaf, wherein a simple petiole has several leaflets fastened to each side of it.

Conjugate. Having only one pair of leaflets.

Bijugate, having two; trijugate, having three; quadrijugate, having four pairs of leaflets.

Pinnate unequally. Terminated by a single or odd leaflet.

P. abruptly. Not terminated either by a leaflet or tendril.

P. cirrhosely. Terminated by a tendril.

P. oppositely. Having the leaflets placed over against each other in pairs.

P. alternately. Having the leaflets alternate along the common petiole.

P. interruptedly. Having smaller leaflets interposed between the principal ones.

P. articulately. When the common petiole is jointed.

P. decursively. When the leaflets run into one another along the common petiole.

PINNATIFID LEAF. By the Lichfield society called featherclef. Transversim divium lacinis horizontalibus oblongis. A species of simple leaf, divided transversely by oblong horizontal segments or jags; not extending to the midrib.

PINNEBERG, a town of Lower Saxony, in the duchy of Holstein, capital of a lordship, with a castle. It is seated on the Owe, 15 miles N.W. of Hamburg, and 16 S.E. of Gluckstadt.

PINNER. *s.* (from *pinna*, or *pinion*.) 1. The lappet of a head which flies loose (*Addison*). 2. A pinmaker (*Ainsworth*).

PINNULATE LEAF, or **PINNA**. When each pinna is subdivided.

PINOS, an island of the W. Indies, on the S. side of Cuba, 25 miles long and 15 broad, mountainous, and covered with pines. Lon. 82. 33 W. Lat. 22. 2 N.

PINSK, a town of Lithuania, in the palatinate of Brzesc. There are many Jews among the inhabitants, and the Greeks have a bishop. The chief manufacture is dressing Russian leather. It is surrounded by morasses, and stands on a river of the same name, 95 miles E. of Brzesc. Lon. 26. 20 E. Lat. 52. 18 N.

PINT, (*pinta*), a vessel, or measure, used in estimating the quantity of liquids, and even sometimes of dry things. Budæus derives the word from the Greek *πνιτα*; others from the German *pint*, a little measure of wine; Nicod from the Greek *πνιτα*, to drink. The English pint is twofold; the one for wine-measure, the other for beer and ale-measure, the former being equivalent to 28 $\frac{1}{2}$ cubic inches, the latter to 35 $\frac{1}{2}$ inches. The pint among druggists and medical men is 12 ounces.

PINTADO, in ornithology. See **NUMIDIA**.

PINTLES, certain pints or hooks fastened upon the back part of the rudder, with their points downwards, in order to enter into, and rest upon, the googings, fixed in the stern-post, to hang the rudder. See **HELM**.

PINTOR (Peter), born at Valencia in Spain, in the year 1420, was physician to Alexander VI. whom he followed to Rome, where he practised with great success. He has left behind him two performances of considerable merit, 1. *Aggregator Sententiarum Doctorum de Curatione in Pestilentia*, printed at Rome 1499, in folio. 2. *De Morbo Fædo et Occulto his Temporibus affligenti*, &c. printed at Rome, 1500, in 4to, black letter; a book extremely scarce, unknown to Luisini and Astruc, and which traces the venereal disease to the year 1496. Pintor died at Rome in 1503, aged 83 years.

PINULES. *s.* In practical astronomy, the sights of an astrolabe.

PINTURICCIO (Bernardino), a celebrated Italian painter, born at Perugia in 1454: and the inventor of a new way of painting to represent the basso relievo of architecture. He principally painted history, though he excelled in portraits. His greatest work was in the library of Sienna. He died in 1513.

PINUS, in botany, a genus of the class monœcia, order monadelphia. Male: calyx a peltate scale of the ament; corolless; anthers growing to the scales, sessile. Female: calyx a two-flowered scale of the cone; corolless; nuts two under each scale, winged. Thirty-three species; a few Asiatic, more European; most American trees. They may be thus distinguished into two sections.

A. Leaves numerous from the same sheathing base; constituting the tribe of firs.

B. Leaves solitary surrounding the branches; the tribe of pines.

The following are those chiefly worthy of notice.

1. *P. sylvestris*. Scotch fir. Leaves in pairs, rigid; younger cones peduncled, recurved, dependent; anthers with a minute crest. This tree yields a red or yellow deal of great durability: grows wild in Scotland.

2. *P. pinaster*. Wild pine. Lofty tree, with wide spreading branches, which when young, and especially if exposed to a free influx of air, are full of leaves, but become bald by age, or when in a confined spot. The tree has then in its lower and older branches a very unsightly appearance. A native of the south of Europe.

3. *P. pinea*. Stone-pine tree. Leaves in pairs; cones ovate, very large; seeds with very short wings; anthers with a jagged toothed crest, kidney-form. A native of the south of Europe.

4. *P. strobus*. Weymouth pine. Leaves in fives; cones cylindrical, smooth, longer than the leaves; anthers with a double subulate minute crest. A native of North America. It rises often to the height of a hundred feet, and is peculiarly valuable for its elegance. The bark is smooth and delicate; and the

wood employed for masts of ships. Within the last half century it has been very largely propagated in England.

5. *P. abies*. Spruce fir. Leaves solitary, square; cones cylindrical, the tops rhombic, flattened, repand, and notched at top. A native of Europe and Asia. This species includes the Norway spruce, and long-coned Cornish fir. The former is equally valuable for its beauty as a tree as for its wood, when cut for timber; it forms the white deal of the joiners, and produces the common pitch of the shops. Its shaft is upright and very tall. The cones are pendulous, eight or ten inches long.

6. *P. picea*. Silver fir. Leaves solitary, flat, a little inclining to one side, glaucous; branches horizontal; bractes twice as long as the scale; cones cylindrical, erect, sessile; scales very obtuse, with ciliate teeth at the sides; crest of the anthers two-horned. A native of the Alps; very hardy, and will grow in any situation, but always makes the greatest progress in a rich loamy soil, with space for its roots to strike out freely.

7. *P. balsamea*. Balm of Gilead fir. Leaves solitary, flat, a little inclining to one side; cones cylindrical, erect, with short bractes; crest of the anthers not horned. A native of Virginia. This species has been more coveted than any of the tribe; its leaves are highly fragrant; it is also a beautiful upright tree, with branches as ornamental in their regularity as they are desirable for their odour. It requires a deep rich earth, and will not flourish in any other.

8. *P. cedrus*. Cedar of Lebanon. Leaves fascicled, perennial; cones ovate, obtuse, erect, with oppressed, rounded scales. This is also an elegant and odoriferous species. Its wood is sometimes counterfeited by dying other close-grained timber of the same hue; but the want of fragrance detects the cheat at once. The wood of the cajon tree is sometimes passed for cedar from its reddish colour and aromatic smell, in which, however, it more nearly resembles santal wood. Cedar is reputed almost incorruptible; and in truth its bitter taste effectually preserves it from worms that prey upon wood generally. Among the ancients a juice was obtained from this wood with which they varnished or at least stained their books, writings, and other materials, to preserve them from rotting.

It is a native of Syria, chiefly about Mount Libanus; nor has it yet been found any where else as an indigenous plant. The cedar of Lebanon mentioned in the scriptures, however, does not appear to have been the species before us: since the former is characterised as being peculiarly lofty, a term which by no means applies to the cedar now existing on that mountain as described by modern travellers, which, like those of the same name grown in Europe, spread very wide, but by no means grow very lofty. Maundrel remarks, that when he visited mount Libanus there were but sixteen large trees, some of which were of a prodigious bulk; but there were many young trees of a much smaller size. He measured one of

P I N U S.

the largest, and found it to be twelve yards six inches in girth, and thirty-seven yards in the spread of its branches; it is probable, however, that by the word spread, this writer means diameter.

9. *P. larix*. Larch. Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflected, jagged; bractes guitar-shaped. It is a native of the Alps, with branches pendulous at the tips and ascending cones: grows quickly, and reaches fifty feet high.

From the larch-tree is extracted what we erroneously call Venice turpentine. This substance, or natural balsam, flows at first without incision; and when it has done dropping, the poor people who wait in the fir woods make incisions at about two or three feet from the ground into the trunks of the trees, into which they fix narrow troughs about twenty inches long. The end of these troughs is hollowed like a ladle; and in the middle is a small hole bored for the turpentine to run into the receiver which is placed below it. As the gummy substance runs from the trees, it passes along the sloping gutter or trough to the ladle, and from thence runs through the hole into the receiver. The people who gather it visit the trees morning and evening from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, Venice turpentine is clear like water, and of a yellowish white, but as it grows older, it thickens and becomes of a citron colour. It is procured in the greatest abundance in the neighbourhood of Lyons, and in the valley of St. Martin, near St. Lucern in Switzerland.

All sorts of pines are propagated by seeds produced in hard woody cones. The way to get the seeds out of these cones is to lay them before a gentle fire, which will cause the cells to open, and then the seeds may be easily taken out. If the cones are kept entire, the seeds will remain good for some years; so that the surest way of preserving them is to let them remain in the cones till the time for sowing the seeds. If the cones are kept in a warm place in summer, they will open and emit the seeds; but if they are not exposed to the heat, they will remain close for a long time. The best season for sowing the pines is about the end of March. When the seeds are sown, the place should be covered with nets to keep off the birds; otherwise, when the plants begin to appear with the husk of the seed on the top of them, the birds will peck off the tops, and thus destroy them.

From the first species is extracted the common turpentine, much used by farriers, and from which is drawn the oil of that name. The process of making pitch, tar, rosin, and turpentine, from these trees, is this: in the spring time, when the sap is most free in running, they pare off the bark of the pine tree, to make the sap run down into a hole which they cut at the bottom to receive it. In the way, as it runs down, it leaves a white matter like cream, but a little thicker. This is very different from all the kinds of resin and tur-

pentine in use; and is generally sold to be used in the making of flambeaux, instead of white bees' wax. The matter that is received in the hole at the bottom is taken up with ladles, and put in a large basket; a great part of this immediately runs through, and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, adding a large quantity of water. They distil this as long as any oil is seen swimming on the water. This oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine. The remaining matter at the bottom of the still is common yellow resin. When they have thus obtained all they can from the sap of the tree, they cut it down; and hewing the wood into billets, they fill a pit dug in the earth with these billets; and setting them on fire, there runs from them, while they are burning, a black thick matter. This naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil. If this hole is made too large, it sets the whole quantity of the tar on fire; but if small enough, it runs quietly out. The tar being thus made, is put up in barrels; and if it is to be made into pitch, they put it into large boiling vessels, without adding any thing to it. It is then suffered to boil awhile, and being then let out, is found when cold to be what we call pitch.

A decoction of the nuts or seeds of the first species in milk, or of the extremities of the branches pulled in spring, is said, with a proper regimen, to cure the most inveterate scurvy. The wood of this species is not valued; but that of the Scots pine is superior to any of the rest. It is observable of the Scots pine, that when planted in bogs, or in moist soil, though the plants make great progress, yet the wood is white, soft, and little esteemed; but when planted in a dry soil, though the growth of the trees is there very slow, yet the wood is proportionably better. Few trees have been applied to more uses than this. The tallest and straightest are formed by nature for masts to our navy. The timber is resinous, durable, and applicable to numberless domestic purposes, such as flooring and wainscoting of rooms, making of beds, chests, tables, boxes, &c. From the trunk and branches of this, as well as most others of the pine tribe, tar and pitch are obtained. By incision, barras, Burgundy pitch, and turpentine, are acquired and prepared. The resinous roots are dug out of the ground in many parts of the Highlands, and being divided into small splinters, are used by the inhabitants to burn instead of candles. At Loch Broom, in Rosshire, the fishermen make ropes of the inner bark; but hard necessity has taught the inhabitants of Sweden, Lapland, and Kamtschatka, to convert the same into bread. To effect this, they, in the spring season, make choice of the tallest and

PIO

fairest trees, then stripping off carefully the outer bark, they collect the soft, white, succulent, interior bark, and dry it in the shade. When they have occasion to use it, they first toast it at the fire, then grind, and after steeping the flour in warm water to take off the resinous taste, they make it into thin cakes, which are baked for use. On this strange food the poor inhabitants are sometimes constrained to live for a whole year; and we are told, through custom, become at last even fond of it. Linnéus remarks that this same bark bread will fatten swine; and humanity obliges us to wish that men might never be reduced to the necessity of robbing them of such a food. The interior bark of which the above mentioned bread is made the Swedish boys frequently peel off the trees in the spring, and eat raw with a greedy appetite. From the cones of this tree are prepared a diuretic oil, like the oil of turpentine, and a resinous extract, which has similar virtues with the balsam of Peru. An infusion or tea of the buds is highly commended as an antiscorbutic. The farina, or yellow powder, of the male flowers, is sometimes in the spring carried away by the winds, in such quantities, where the trees abound, as to alarm the ignorant with the notion of its raining brimstone. The tree lives to a great age; Linnéus affirms, to 400 years.

PIOMBINO, a small principality of Italy, on the coast of Tuscany, to which was annexed the island of Elba, separated by a channel seven miles broad. It had its own prince, under the protection of Naples; but the continental part now belongs to Etruria, and the island to France.

PIOMBINO, a seaport of Italy, capital of the principality of the same name. It has a good harbour, defended by a citadel, and is seated on a peninsula, 40 miles S.E. of Leghorn. Lon. 10. 23 E. Lat. 42. 57 N.

PIONEERS, in the art of war, are such as are commanded in from the country, to march with an army for mending the ways, for working on intrenchments and fortifications, and for making mines and approaches. The soldiers are likewise employed for all these purposes. Most of the foreign regiments of artillery have half a company of pioneers, well instructed in that important branch of duty. Our regiments of infantry and cavalry have about twenty pioneers each, provided with aprons, hatchets, saws, spades, and pick-axes. Each pioneer must have an ax, a saw, and an apron; a cap with a leather crown, and a black bear-skin front, on which is to be the king's crest in white, on a red ground; and the number of the regiment is to be on the back part of it.

PIONING. *s.* Works of pioneers (*Spen.*).

PIOUS. *a* (*pius*, Lat. *pieux*, Fr.) 1. Careful of the duties owed by created beings to God; godly; religious; such as is due to sacred things (*Milton*). 2. Careful of the duties of near relation (*Taylor*). 3. Practised under the appearance of religion (*King Charles*).

PIOUSLY. *ad.* (from *pious*.) In a pious

PIP

manner; religiously; with such regard as is due to sacred things (*Philips*.)

PIP, or **PEP** (*pepia*), a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding. It usually arises from want of water, or from drinking puddle-water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with salt. Hawks are particularly liable to this disease, especially from feeding on stinking flesh.

PIP, a spot on the cards.

To PIP. *v. n.* To chirp or cry as a bird (*Boyle*).

PIPE, in building, &c. a canal, or conduit, for the conveyance of water and other fluids. Pipes for water, water-engines, &c. are usually of lead, iron, earth, or wood: the latter are commonly made of oak or elder. Those of iron are cast in forges; their usual length is about two feet and a half; several of these are commonly fastened together by means of four screws at each end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them the closer, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron pipes. The wooden pipes are trees bored with large iron augurs, of different sizes, beginning with a less, and then proceeding with a larger successively; the first being pointed, the rest formed like spoons, increasing in diameter, from one to six inches or more: they are fitted into the extremities of each other, and are sold by the foot.

PIPE-BORING. *AA*, Plate 139, fig. 1, are two beams laid on each side of a pit, into which the chips are to fall. Upon the edges of these, the wheels of a frame *DE* run. This frame has four pieces, *ddaa*, across it; and two windlases, *bb*, which have chains round them, going over the piece of timber *F* which is to be bored. The two end-pieces *dd* have uprights *ee* in them; between which the tree is laid, and is secured with wedges in different places as the occasion requires. *G* is a piece lying across the two beams *AA*: this is connected with the frame *DE* by two iron bars *ff*, which are fastened to it; and go through holes in the piece *d*, and are held there by pins put through holes in both. The piece *G* has two uprights in it, between which is a brass pulley to support the weight of the boring-bar *H ghi* is a wheel, with handles on its circumference to turn it by; on its axis *I* a rope is coiled; one end of which goes over a pulley (not seen), and is fastened to the carriage *DE*. At *i* the other end goes over a similar pulley, and is tied to the other end of the carriage *DE*. The machine is put into some place where there is a crane, by which the tree can be lifted upon the carriage; first withdrawing the carriage from the boring-bar, by turning the wheel from *g* to *i*, and separating it from the piece *G*

by taking out the pins. It is then wedged into its place, and secured by the windlasses *bb*. The wheel is next turned back, the carriage drawn up to the borer, and the piece *G* pinned in. The machine (either horses, water, steam, &c.) which turns the borer is then set to work; and a man constantly attends at the wheel *ghi*, to draw the pipe up to the borer. The use of the wheel in the piece *G* is, to support the borer just where it enters the pipe, and make it work steady. When the pipe is bored through, it is withdrawn, and another tree is placed on the carriage as before.

The company for the Manchester water-works employ stone pipes for the communication of the water. The stone which they have found as most suitable to their purpose, is in a quarry at Fox Hill, in the parish of Guiting Power, Gloucestershire. The stone is much of the same quality as Portland stone, though not quite so dense, the Fox Hill stone requiring 17 cubic feet to weigh a ton, while the Portland stone requires only 16 feet.

The works at Fox Hill for the purpose of boring the stone are ingeniously constructed. The first mover is a steam engine of considerable power, giving rotatory motion to a shaft posited horizontally, and running from one end of the works to the other. The works are divided into compartments, each of which serves for the simultaneous boring of four pipes. By means of the usual contrivance of bevel-gear motion is communicated from the main horizontal shaft, to a vertical arbor, at the top of which is the wheel *A* (fig. 2. pl. 139). The rotatory motion of this wheel by means of a crank bar *CD*, gives a reciprocating motion to the larger wheel *B*, and this latter motion is such as to give rather more than a complete rotation to each of four smaller wheels, 1, 2, 3, 4, placed diametrically opposite, with respect to the larger wheel *B*, the mutual connection between them and it being by means of teeth or cogs. Thus the wheels 1, 2, 3, 4, go through somewhat more than a complete rotation in one direction, and then rather more than a complete rotation in the opposite direction; and so on alternately. On the vertical shafts beneath the wheels 1, 2, 3, 4, are placed iron tubes which are suffered to act by their weights upon the stones to be bored, and by means of their rotation to bore those stones by attrition. The stones are cut into lengths of 6 or 8 feet, and bored into pipes of various diameters. When the pipes are of 14 inches diameter, the thickness of stone allowed is about 5 inches. The tubes by which the boring is effected are then of course 14 inches diameter, and weigh about $1\frac{1}{2}$ cwt. They are made of thin plate iron, except their circular rim or sole at the bottom, which is about half an inch thick. As the attrition wears away the stones on which the soles of the tubes rest, they sink lower and lower; the whole is kept moist by means of a semifluid mixture of sand and water, which runs down from the wheels 1, 2, 3, 4, at top of the tubes, and after sinking to the bottom of those tubes, carries up with it the particles of

the stone taken off during the process of boring. Thus the boring proceeds with tolerable rapidity. The principal defect we saw in the machinery was in the jostling occasioned by the bar *CD* on every reciprocation of the wheel *B*: but this may be easily remedied.

Previously to the adoption of these tubes for boring, the work was effected by the circular saws invented by sir James Wright: but these saws were soon abandoned, by reason of their frequent derangement, when multiplied and worked by machinery.

PIPES OF AN ORGAN. See ORGAN.

PIPES (Tobacco), are made of various fashions; long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c. The Turks use pipes three or four feet long, made of rushes, or of wood bored, at the end whereof they fix a kind of pot of baked earth, which serves as a bowl, and which they take off after smoking. With us the tobacco pipe manufactory is a branch of pottery; but the methods being essentially different from any other, and very ingenious, deserve a more particular notice than at first sight might be imagined.

The clay of which tobacco pipes are made is perfectly white, and is distinguished from other kinds of clay by its great adhesion to the tongue, which is well known to be very considerable when baked, in consequence of its affinity for water; in the raw state this property is perceptible in a slight degree. The pipe clay is found at Maidenhead, in Kent, in large lumps, which are purified by dissolving them in water in large pits; this solution being well stirred up, is poured off into another, where it subsides and deposits the clay; the water becoming clear is run off, and the clay at the bottom is left till sufficiently dry for use; by this means the smallest stones or particles of foreign matter are left at the bottom of the first pit; the clay thus prepared, is spread on a board and beaten with an iron bar, to temper and mix it; then it is divided into pieces, each of which will be the proper size to form a tobacco pipe; each of these pieces is rolled under the hand into a long roll with a bulb at one end to form the bowl, and in this state they are laid up in parcels for a day or two, until they become sufficiently dry for pressing, which is the next process, and is conducted in the following manner. The roll of clay has a small wire (fig. 5. pl. 138) thrust nearly through its whole length to form the tube, and is put in between two iron moulds, one of which is shown in fig. 6. of the same plate, 138. each has imprinted in it the figure of one half of a pipe, and therefore when put together, the cavity between them is the figure of a whole pipe. They are put together by 3 pins at *a, b, c*, which enter holes in the opposite half. The moulds, with the clay in them, are now put into the press, figs. 1. and 2. It consists of an iron frame formed of two plates like *dd*, one of which is fixed down to the bench *AA*, and the other is pressed towards it by a screw, turned round by the handle *e*. The

moulds are put in between the two plates, and the screw being turned round presses them together, imprinting the figure of a pipe on the clay included between them. The lever *k* is next depressed, and the stopper *l* (shown enlarged in fig. 3.) entering the mould, forms the bowl of the pipe, and the wire, fig. 5. which is all the while in the pipe, is thrust backwards and forwards to prick the tube completely into the bowl. The press is now opened by turning back the screw *e*, and the moulds taken out. The knife, fig. 4. is thrust into the cleft *d* fig. 6. of the mould to cut the end of the bowl flat, the wire is carefully withdrawn, and the pipe taken out of the mould. These pipes are laid up 2 or 3 days, till they become stiff, when they are dressed with curved scrapers to take off the impression of the joints of the moulds, and they are polished and smoothed by rubbing them with a piece of hard wood cut with a semicircular cleft. They are then baked in the furnace, figs. 7 and 8. It is built within a cylinder of brickwork AA, having a dome at top, and a chimney B arising from it to a great height, to cause a sufficient draught. Within this is a lining of fire brick marked CC, having the fire-place D, at the bottom of it. The pot or crucible EE, which contains the pipes, is formed of broken pieces of pipes, and cemented together by fresh clay and hardened by burning. This crucible has a number of vertical flues surrounding it, as shown in the plan fig. 7, and conducting the flame from the fire grate up to the dome of the fire brick lining CC, and through a hole in its dome into the chimney. Within the crucible several projecting rings are made, and upon these the bowls of the pipes are supported as in the figure at *aa*; the ends resting upon circular pieces of pottery which stand on small loose pillars *dd* set up for the purpose in the center. By this arrangement a small crucible can be made to contain 50 gross of pipes, and without loading them one upon the other so as to endanger the crushing or deforming any by the weight of the others. The pipes are put into the pot at one side where the crucible is open, but when filled, this orifice is made up with broken pipes and fresh clay. The fire brick lining CC is also made good on that side, and the furnace is lighted. At first the heat is gentle, but is increased by degrees to the proper temperature, and continued for 7 or 8 hours; when it is damped by stopping the hole in the crown of the lining CC with a flat plate of fire clay.

When the furnace is cold the pipes thus baked are ready for sale.

PIPE, also denotes a vessel or measure for wine, and things measured by wine-measure. It is usually reckoned two hogsheds, or 126 gallons: this is the measure found in books, but in actual life it is very different.

Gallons.

The pipe of Port is	- - - - -	138
The pipe of Madeira is	- - - - -	110
The pipe of Vidonia is	- - - - -	120
The pipe of Sherry is	- - - - -	130
The pipe of Lisbon, and Bucellas, is	- 140	

The pipe of port is seldom accurately 138 gallons, and it is customary in trade to charge what the cask actually contains, be it more or less than the estimated quantity.

PIPE, in music, any tube formed of a reed, or of wood, metal, &c. which being inflated at one end produces a musical sound, acute or grave, soft or loud, according to the material, its form, and dimensions. The pipe, which was originally no more than a simple oaten straw, formed one of the first instruments by which melodious sounds were attempted.

PIPES OF PAN, or MOUTH ORGAN, a wind instrument consisting of a range of pipes bound together side by side, and gradually lessening with respect to each other in length and diameter. The longest is about six inches, and the shortest only two in length. In performing upon this instrument, it is held in the hand, and the pipes are blown into by the mouth at the upper end. This is the syrinx or fistula of Theocritus, Lucretius, and Virgil.

PIPE, in law, a roll in the exchequer, otherwise called the *great roll*, whence there is an office called the pipe office, where they take cognizance of estreats and forfeitures to the King. The clerk of the pipe makes out leases of crown lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer. The clerk of the pipe makes out also accounts of sheriffs, &c. and gives the accomptants their *quietus est*. To this office are brought all accounts which pass the remembrancer's office, and remain there, that if any stated debt is due from any person, the same may be drawn down into the great roll of the pipe; upon which the comptroller issues out a writ, called the summons of the pipe, for recovery thereof; and if there are no goods or chattels, the clerk then draws down the debts to the lord-treasurer's remembrancer, to write estreats against their lands. All tallies which vouch the payment of any sum contained in such accounts are examined and allowed by the chief secondary of the pipe. Besides the chief clerk in this office, there are eight attorneys, or sworn clerks, and a comptroller.

PIPE (Wind). See TRACHEA.

To PIPE. *v. n.* (from the noun.) 1. To play on the pipe (*Camden*). 2. To have a shrill sound (*Shakspeare*.)

PIPE, in botany. See SYRINGA.

PIPE-TREE FUDDING. See CASSIA.

PIPE-CLAY, in mineralogy, a species of the argillaceous earth called argil. See ARGILLA.

PIPE-FISH, in ichthyology. See SYNGNA-THUS.

PIPER, a performer on a pipe. Pipers were formerly one of the class of itinerant musicians, and performed on a variety of wind instruments: as the bag-pipe, musette, court-taut, &c.

PIPER. Pepper. In botany, a genus of the class diandria, order trigynia. Calyxless; corollless; berry one-seeded. Fifty-one species, chiefly West Indian or American plants; some, natives of the East Indies; a few of

the Cape. The following are those chiefly noticeable.

1. *P. nigrum*. Leaves ovate, mostly seven-nerved, glabrous; petioles very simple. A native of India, with trailing stem, rooting at the joints; leaves ovate, alternate, mostly seven-nerved, glabrous, or sheath-like foot-stalks; flowers sessile, lateral and terminal. The berries are the common black pepper; and when deprived of their skin and steeped in water, they constitute white pepper.

2. *P. betle*. Betel. Stems striate-angular; leaves ovate, rather oblong, pointed, seven-nerved, alternate; petioles two-toothed, channelled; spike cylindrical. A native of India, cultivated by props like the vine; the areca is a common prop; and the leaves inclosing a few bits of areca which correct their bitterness, are universally chewed by the Asiatics, and form a common present from friend to friend. It would be a breach of politeness among the Indians to take leave for any long time without presenting each other with a purse of betel. No one dares speak to a superior unless his mouth is perfumed with betel. Women of gallantry are most lavish in the use of it. It is taken after meals, and chewed during a visit. It is certainly prejudicial to the teeth; but is said to strengthen the stomach.

3. *P. siriboa*. Leaves heart-shaped, mostly seven-nerved, veined, alternate, acute; spikes axillary, slender. This is also a native of India, and yields a pepper of a similar kind to *P. nigrum*. The pepper is produced from white flower-buds, and at first resembles bunches of currants, about twenty or thirty being in a bunch.

4. *P. cubeba*. Stem jointed, flexuous; leaves unequal at the base. The pedicelled berries are the cubebæ of the shops. It is a native of Java and Guinea. For the medical properties of its berries, see *CUBEBÆ*.

5. *P. longum*. Stems shrubby, climbing; leaves heart-shaped, entire, alternate. The long pepper of the shops. A native of India.

6. *P. methysticum*. Stem forked, spotted; leaves oblong, heart-shaped; spikes axillary, solitary, straight. The root bruised, and chewed, and mixed with the saliva, forms the intoxicating juice called *ava*, which is so agreeable to the natives of the South Sea Islands, to which the plant is indigenous.

About eight species of this genus are cultivated in our own conservatories by seeds procured fresh from the countries to which the plants respectively belong.

PIPER, in ichthyology. See *TRIGLA*.

PIPER INDICUM. Capsicum. *Piper Braziliannum*. *Piper Guineense*. *Piper Calcutticum*. *Piper Hispanicum*. *Piper Lucitanicum*. Cayenne pepper. Guinea pepper. This species of pepper is obtained from the capsicum annuum; caule herbaceo, pedunculis solitariis of Linnæus. *C. O. Pentandria*. *Monogynia*. As an aromatic of the stimulant kind, it is efficacious in some paralytic and gouty cases, or to promote excitement where the bodily organs are languid and torpid.

PIPER JAMAICENSE. See *PIMENTO* and *MYRTUS*.

PIPERIDGE TREE. See *BERBERIS*.

PIPERITÆ. (*piper*, pepper.) The name of the first order in Linnæus's Fragments; and of the second, in his Natural Orders.

PI'PING. *a.* (from *pipe*.) 1. Weak; feeble; sickly (*Shakspeare*). 2. Hot; boiling.

PI'PKIN. *s.* (diminutive of *pipe*.) A small earthen boiler (*Pope*).

PIPPIN. *s.* (*puppynghe*, Dutch. *Skinner*.) A sharp apple. See *PYRUS*.

PIPRA. Manakin. In zoology, a genus of the class aves, order passeræ. Bill shorter than the head, strong, hard, nearly triangular at the base, and slightly incurved at the tip; nostrils naked; feet gressorial; tail short. Thirty-one species; inhabitants of the warm climates of Asia, Africa, and America. The following are chiefly worthy of notice.

1. *P. rupicola*. Rock or crested manakin. Crest erect, edged with purple; body saffron; tail-coverts truncate. Inhabits the rocky parts of South America; size, that of a small pigeon; from ten to twelve inches long; shy, but may be tamed if taken young; feeds on small wild fruits, and builds in the clefts of the remotest rocks; eggs two, white. The bill is yellowish; crest consists of a double series of feathers; quill-feathers partly white, partly brown; tail-feathers twelve, upper half of the ten middle ones orange, lower half brown, outer ones brown; legs yellow. Female and young birds brown; lower wing-coverts rufous-orange.

2. *P. musica*. Tuneful manakin. Black, beneath orange; front and rump yellow; crown and nape blue; chin and throat, bill and legs, black. Inhabits St. Domingo; four inches long; is very shy, and easily eludes the vigilance of such as attempt to take it, by perpetually shifting, like the creeper, to the opposite branches of the tree: its note is musical, and forms a complete octave, one note regularly succeeding another.

PI'QUANCY. *s.* (from *piquant*.) Sharpness; tartness.

PI'QUANT. *a.* (*piquant*, French.) 1. Pricking; piercing; stimulating (*Addison*). 2. Sharp; tart; pungent; severe (*Bacon*).

PI'QUANTLY. *ad.* Sharply; tartly (*Locke*).

PIQUE. *s.* (*pique*, French.) 1. An ill will; an offence taken; petty malevolence (*Decay of Piety*). 2. A strong passion (*Hudibras*). 3. Point; nicety; punctilio (*Dryden*).

To *PIQUE*. *v. a.* (*piquer*, French.) 1. To touch with envy or virulency; to put into fret; to kindle to emulation (*Prior*). 2. To offend; to irritate (*Pope*). 3. To value; to fix reputation as on a point (*Locke*).

To *PIQUEER*. See To *PICKEER*.

PIQUEERER. *s.* A robber; a plunderer; rather *pickeerer* (*Swift*).

PIQUET. See *PICQUET*.

PIQUETRA, in botany, a genus of the

class syngenesia, order polygamia æqualis. Receptacle naked; calyx four-leaved, equal, four-flowered; downless; seeds five-sided. One species; a Mexico plant with white flowers.

PIQUETTES, in botany. See **DIANTHUS**.

PIRACY. *s.* (*ωιγαλμα*.) The act or practice of robbing on the sea (*Waller*).

PIRÆUS, or **PIREUS**, a celebrated harbour at Athens, at the mouth of the Cephissus, about three miles distant from the city. It was joined to the town by two long walls, one of which was built by Themistocles, and the other by Pericles. It was the most capacious of all the harbours of the Athenians, and was made sufficiently commodious for the reception of a fleet of 400 ships in the greatest security. Its walls and fortifications were totally demolished by Lysander.

PIRANESI (Giambattista), an architect and engraver of Venice. He was born about 1711, and was remarkable for a bold and free style of etching, which he generally drew upon the plate at once. He died in 1780.

PIRATE. (*ωιγατης*, Gr.) A sea-robber, or an armed ship that roams the seas without any legal commission, and seizes or plunders every vessel she meets indiscriminately, whether friends or enemies.

The colours usually displayed by pirates are said to be a black field, with a death's head, a battle-axe, and hour-glass. The last instrument is generally supposed to determine the time allowed to the prisoners, whom they take, to consider whether they will join the pirates in their felonious combination, or be put to death; which is often perpetrated in the most cruel manner.

By stat. 28 H. VIII. c. 15, all treasons, felonies, robberies, murders, and confederacies committed upon the sea, or in any haven, creek, or place where the admiral has jurisdiction, shall be tried in such shires or places as the king shall appoint by his commission in like forms, as if such offence had been committed upon land, and according to the course of the common law, and the offenders shall suffer death without benefit of clergy. And by stat. 6 Geo. I. made perpetual, it is enacted, that if any of his majesty's natural-born subjects, or denizens of this kingdom, shall commit any piracy or robbery, or any act of hostility, against other his majesty's subjects upon the sea, under colour of any commission from any prince or state, or pretence of authority from any person whatsoever, such offender shall be deemed to be a pirate, felon, and robber; and being duly convicted thereof according to this act, or the aforesaid act of 23 Hen. VIII. shall have and suffer such pains of death, loss of lands, goods, and chattels, as pirates, felons, and robbers upon the seas, ought to have and suffer. By 18 Geo. II. c. 30. persons committing hostilities, or aiding enemies at sea, may be tried as pirates. Piracies at sea are excepted out of the general pardon, by 20 Geo. II. c. 52.

Pirate's goods go to the admiral by grant; but not piratical goods, which go to the king if the owner is not known.

To **PIR'ATE**. *v. n.* (from the noun.) To rob by sea (*Arbutnot*).

To **PIR'ATE**. *v. a.* (*pirater*, Fr.) To take by robbery (*Pope*).

PIRATICAL. *a.* (*piraticus*, Latin.) 1. Predatory; consisting in robbery (*Bacon*). 2. Practising robbery (*Pope*).

PIRENE, in fabulous history, a daughter of Cebalus, or according to others, of the Achelous. She had by Neptune two sons called Leches and Cenchrius, who gave their name to two of the harbours of Corinth. Pirene was so disconsolate at the death of her son Cenchrius, who had been killed by Diana, that she pined away, and was dissolved by her continual weeping into a fountain of the same name at Corinth. This fountain was sacred to the Muses.

PIRITHOUS, in fabulous history, a son of Ixion and the cloud. Some make him son of Dia, by Jupiter, who assumed the shape of a horse whenever he paid his addresses to his mistress. He was king of the Lapithæ, and he wished to become acquainted with Theseus king of Athens, of whose exploits he had heard so much. To be a witness of his valour, he resolved to invade his territories, and Theseus immediately met him on the borders of Attica; but their meeting, instead of proving hostile, was like that of the most cordial friends, and Pirithous promised to repair the damages which his hostilities occasioned. From that time the two monarchs became so attached, that their friendship, like that of Orestes and Pylades, is proverbial. Pirithous some time after married Hippodamia, and invited not only heroes, but also the gods themselves, and his neighbours the centaurs, to celebrate his nuptials. Mars was the only god not invited. He therefore determined to raise a quarrel, and to disturb the festivity of the entertainment. Eurythion, intoxicated with wine, attempted to offer violence to the bride, but he was prevented by Theseus, and immediately killed. This irritated the rest of the centaurs, and the contest became general. Many of the centaurs were slain, and the rest saved their lives by flight. (See **LAPITHUS**.) After the death of Hippodamia, Pirithous and Theseus carried off Helen, who fell to the lot of Theseus. Pirithous upon this undertook with his friend to carry away Proserpine and to marry her. They descended into the infernal regions, but Pluto stopped the two friends, and confined them there. Pirithous was tied to his father's wheel, or according to Higynus, he was delivered to the Furies to be continually tormented; but when Hercules visited the kingdom of Pluto, he obtained the pardon of Pirithous, and brought him back unhurt. Some suppose that he was torn to pieces by the dog Cerberus. (See **THESEUS**.)

PIRMASENS, a town of France, in the department of Mont Tonnere, lately of Germany, in the duchy of Deux Ponts. Near

this place, in 1793, the French were defeated by the Prussians. It is 13 miles E. of Deux Ponts.

PIRNA, a town of Upper Saxony, in Misnia. It has a castle on a mountain, called Sonnenstein, which was almost destroyed by the Prussians in 1756 and 1758, and is now an asylum for invalids, &c. It is a place of considerable trade, situate on the Elbe, 12 miles S.E. of Dresden.

PISA, a city of Tuscany, capital of the Pisano, and an archbishop's see, with a famous university, and three forts. The river Arno runs through Pisa, and over it are three bridges, one of which is constructed of marble; and there is a canal hence to Leghorn. This city formerly contained 100,000 inhabitants, but there are not at present above 22,000, so that grass grows in some of the streets. The manufactures consist of steel, jewellery, embroidery, damasks, velvet, taffeta, and calico. The cathedral is a magnificent structure, and on the right side of the choir is a leaning tower, much noticed by travellers. There are upward of 80 more churches, and that of St. Stephen, belonging to an order of knights, is deserving of notice. The other remarkable buildings are the palaces of the grand duke and archbishop, the arsenal, the great hospital, and the magnificent exchange, which last is almost superfluous, as the trade of Pisa is removed to Leghorn. But one of the most extraordinary objects here is the campanile, or leaning tower, erected in a square close to the great church. It is composed wholly of white marble, and was built for the purpose of containing the bells. Its height is about 200 feet, and its inclination nearly fifteen feet from the perpendicular. Mr. Tappen, who has given an interesting description of this tower, in his ingenious *Professional Observations on the Architecture of France and Italy* (pp. 62—65), assigns various reasons for concluding that the deviation from the vertical line is occasioned by want of care in laying the foundation of the tower. To the N. of the city are celebrated baths, constructed at the expense of the hospital of Pisa; and the revenues arising from them are appropriated to the hospital. This city was possessed and evacuated by the French republicans, in the same manner as that of Leghorn. It is seated in a fertile plain, at a small distance from the Mediterranean, 11 miles N.N.E. of Leghorn, and 42 W. by S. of Florence. Lon. 10, 23 E. Lat. 43. 43 N.

PISANO, a territory of Tuscany, lying W. of the Florentino, on the Mediterranean. It is 47 miles long and 25 broad; abounds in corn, oil, wine, and is well cultivated; but some of the necessities of life are dear. Pisa is the capital.

PISAN (Thomas), an astrologer of Bologna, who was invited to Venice by Dr. Forli, counsellor of the republic, who gave him his daughter in marriage. Charles V. of France sent him an invitation to come to his court, which he accepted in 1380. He is said to have pre-

dicted the day of his death, and to have fulfilled that prediction.

PISAN (Christina de), daughter of the above, born at Venice about 1363, was a beautiful woman and an accomplished writer. She wrote the *Life of Charles V.* which occasioned her to be patronized by Charles VI. of France.

PISCARY, in our ancient statutes, the liberty of fishing in another man's waters.

PISCATAQUA, a river of New Hampshire, the mouth of which forms the only port in that state, and at its entrance is a light-house in lon. 76. 41 W. Lat. 43. 4 N.

PISCATAWAY, a town of Maryland, in Prince George county, on a creek of its name, which flows W. into the Potomac, 14 miles S. of Washington.

PISCATION. *s.* (*piscatio*, Lat.) The act or practice of fishing (*Brown*).

PISFACTORY. *a.* (*piscatorius*, Lat.) Relating to fishes (*Addison*).

PISCES. Fishes. In zoology, the fourth class in the Linnéan system, thus classically characterised: jaws incumbent; penis (usually) none; eggs without albumen; possessing organs of sense and tongue; nostrils doubtful; possessing eyes and ears; covering, imbricate scales; supporters, fins; swim in the water, and smack. The class consists of six orders, for which see the articles **ICHTHYOLOGY** and **ZOOLOGY**.

PISCES, in astronomy, the twelfth sign or constellation of the zodiac. The stars in Pisces, in Ptolemy's catalogue, are thirty-eight; in Tycho's thirty-three; and in the Britannic catalogue one hundred and nine, viz. 0, 0, 3, 5, 24, 67, 10.

PISCIDIA. Jamaica dogwood. In botany, a genus of the class diadelphia, order decandria. Stigma acute; legume with four longitudinal wings. Four species, natives of America. The following is most worthy of notice.

P. erythrina. Dogwood-tree. Rises to the height of twenty feet, with a stem as large as a man's body; leaves unevenly pinnate, with ovate leaflets; flowers of a dirty white colour, succeeded by oblong pods which contain the seeds. The bark when pounded is made use of to intoxicate fishes, being first steeped for a night in salt water, when its juice is squeezed out, of a reddish hue, and put into the water in which the fishing takes place. The fishes becoming intoxicated rise to the surface of the stream, and float unconscious of their danger; the negroes attendant upon the fishing party are then sent into the water, who catch them with ease. It has never been found that, though this juice destroys many of the small fry, it produces mischief to those who eat any of the fishes caught by these means. This species of piscidia, and indeed one or two others, are occasionally cultivated in our own conservatories.

PISCIS AUSTRALIS, the southern fish, is a constellation in the southern hemisphere, being one of the forty-eight constellations

mentioned by the ancients. The star *toma-haut*, of the first magnitude, is in the mouth of this fish.

PISCIS VOLANS, the flying fish, in astronomy, is a small constellation of the southern hemisphere, unknown to the ancients, and invisible to us in these northern regions. It contains eight stars; viz. 0, 0, 0, 0, 7, 1.

PISCIVOROUS. *a. (piscis and voro, Lat.)* Fish-eating; living on fish (*Ray*).

PISCO, a town of Peru, in the audience of Lima, with a good road for ships. It is seated in a country fertile in excellent fruits and good wine, 140 miles S.S.E. of Lima. Lon. 76. 15 W. Lat. 13. 36 S.

PISELLO, the most northern cape of *Natolia*, which projects into the Black Sea, opposite the Crimea.

PISH. *interj.* A contemptuous exclamation.

To PISH. *v. n.* (from the interjection.) To express contempt (*Pope*).

PISIFORM BONE, in anatomy, the fourth bone of the first row of the carpus.

PISISTRATUS, an Athenian, who, after he had rendered himself the favourite of the populace by his liberality and his intrepidity, resolved to make himself master of his country. Every thing seemed favourable to his ambitious views; but Solon alone, who had lately enforced his celebrated laws, opposed him, and discovered his duplicity before the public assembly. Pisistratus not disheartened had then recourse to artifice. He cut himself in various places, and after he had exposed his mangled body to the eyes of the populace, deplored his misfortunes, and accused his enemies of attempts upon his life, because he was the friend of the people, he artfully obtained a chosen body of 50 men to defend his person from the malevolence of his enemies. Pisistratus had no sooner received the armed band than he seized the citadel of Athens, and made himself absolute. The people too late perceived their credulity, yet two of the citizens, Megacles and Lycurgus, conspired against him, and by their means he was forcibly ejected from the city. He, however, was shortly after re-established in his power by the assistance of Megacles, who grew jealous of Lycurgus. By means of a woman called *Phya*, whose features were noble and commanding, he imposed upon the people. *Phya* was conducted through the city, and was announced as *Minerva*, the patroness of Athens, who descended from heaven to re-establish her favourite Pisistratus, in a power sanctioned by the will of the Gods. This triumph was but of short duration, as some time after he fled from Athens to *Eubæa*, where he could no longer maintain his power. Eleven years after, he was, by means of his son *Hippias*, a third time received by the people of Athens as their sovereign. Upon this he sacrificed to his resentment the friends of *Megacles*, but he did not neglect the dignity and the honour of the Athenian name. He died about 527 years B. C. after he had enjoyed

the sovereign power at Athens for 33 years, including the years of his banishment, and he was succeeded by his son *Hipparchus*. *Pisistratus* claims our admiration for his justice, his liberality, and his moderation. It is to his labours that we are indebted for the preservation of the poems of *Homer*, and he was the first, according to *Cicero*, who introduced them at Athens, in the order in which they now stand. *Hipparchus* and *Hippias*, the sons of *Pisistratus*, who have received the name *Pisistratidæ*, rendered themselves as illustrious as their father, but the flames of liberty were too powerful to be extinguished; they were at length banished through the means of *Harmodius* and *Aristogiton*, who conspired against them, about 18 years after the death of *Pisistratus*, B. C. 510.

PISMIRE, in entomology. See **FORMICA**.

PISO, a celebrated family at Rome, descended from *Calpus*, the son of *Numa*. Before the death of *Augustus*, eleven of this family had obtained the consulship, and many had been honoured with triumphs, on account of their victories, in the different provinces of the Roman empire. Of this family, the most famous were, 1. *Lucius Calpurnius*, tribune of the people, about 149 years before Christ, and afterwards consul. His frugality procured him the surname of *Frugi*, and he gained the greatest honours as an orator, a lawyer, a statesman, and an historian. 2. *Caius*, a Roman consul, A.U.C. 685, who supported the consular dignity against the tumults of the tribunes, and the clamours of the people. 3. *Cneius*, another consul under *Augustus*, one of the favourites of *Tiberius*. He was accused of having poisoned *Germanicus*, and when he saw that he was shunned by his friends, he destroyed himself, A. D. 20. 4. *Lucius*, a governor of Spain, who was assassinated by a peasant, as he was travelling through the country. 5. *Lucius*, a governor of Rome for twenty years, an office which he discharged with the greatest justice and credit. He was greatly honoured by the friendship of *Augustus*. *Horace* dedicated his poem *De Arte Poetica* to his two sons, whose partiality for literature had distinguished them among the rest of the Romans. 6. *Cneius*, a factious and turbulent youth, who conspired against his country with *Catiline*. He was among the friends of *Julius Cæsar*. 7. *Caius*, a Roman who was at the head of a celebrated conspiracy against the emperor *Nero*. He had rendered himself a favourite of the people by his private as well as public virtues. When the plot was discovered by a freedman, one of the conspirators, he despaired taking any measures for his preservation. He retired to his own house, where he opened the veins of both his arms, and bled to death. 8. *Lucius*, a senator who followed the emperor *Valerian* into Persia. He proclaimed himself emperor after the death of *Valerian*, but he was defeated, and put to death a few weeks after; A. D. 261, by *Valens*,

&c. 9. Lucinianus, a senator adopted by the emperor Galba. He was put to death by Otho's orders.

PISOLITHUS, in mineralogy, a genus of the class earths, order calcareous. Consisting of carbonat of lime, a very small proportion of sand and oxyd of iron, carbonic acid gass, and water; soft, opaque, without lustre internally, breaking into indeterminate fragments, and separating into spherical granulations; of a centrally lamellar texture; found about warm springs. One species; *P. carolinus*. Pisolite. Oolite. Oolithic tufa. *Pisa carolina*. Compact limestone. Found near the warm springs of Carlsbad in Bohemia, in Silesia, and Hungary, in the form of round masses composed of concentric layers, each containing a grain of sand in its centre; colour white or yellowish-white, brownish, reddish, or yellowish.

PISONIA, in botany, so named in honour of William Piso, a physician, a genus of the polygamia dioecia class and order. Natural order of nictagines, Jussieu. Essential character: calyx scarcely any; corol bell-shaped; five-cleft; stamens five or six; pistil one; capsule superior, one-celled; valveless: male and female on the same or on different plants. There are five species.

To PISS. *v. a.* (*pisser*, Fr. *pisssen*, Dutch.) To make water (*L'Estrange*).

Piss. *s.* (from the verb.) Urine; animal water (*Pope*).

PISSABED. See **TARAXACUM** and **LEONDOTON**.

PISSASPALTUS. (*πισσαφαλτης*, from *πισσα*, pitch, and *αελης*, bitumen.) The thicker kind of rock oil.

PISTACHIA, in botany, a genus of the class dioecia, order pentandria. Male: an ament; calyx five-cleft; corolless. Female: flowers distinct; calyx three-cleft; corolless; styles two; drupe dry, one-seeded. Six species; natives of the south of Europe, Barbary, and Asia. The following are chiefly cultivated.

1. *P. vera*. Fistic nut-tree. *Pistachia nut-tree*. Leaves unequally pinnate; leaflets somewhat ovate, recurved, emitting an odour like that of the nut when bruised. Some of the trees produce male, others female flowers; and some, when old, have both on the same tree. The male flowers appear on the sides of the branches in loose bunches; the female flowers appear in the same manner in clusters. It is a native of Persia and India, and may be propagated by seeds or nuts procured from abroad, planted in pots filled with light earth, and plunged into a moderate hotbed. As the plant grows up it should be gradually hardened to bear the external air. The nut is about the size and shape of a filbert, and includes a kernel of a pale greenish colour covered with a yellow or greenish skin. These nuts have a sweetish unctuous taste, resembling that of sweet almonds; and like almonds, afford an oil which may be formed into an emulsion.

2. *P. terebinthus chio*, or *Cyprus turpentine tree*. Leaves unequally pinnate; leaflets seven, ovate-lanceolate: flowers from branching aments at the axils of the leaves. A native of Barbary and the south of Europe; flowering with us in June and July; and may be propagated as the last. It furnishes the chio or *Cyprus turpentine*, which is obtained by wounding the bark of the trunk in several places during the month of July, leaving a space of about three inches between the wounds; from these the turpentine is received on stones, and becomes so much condensed in the course of twenty-four hours, as to admit of being scraped off with a knife, which is always done in the morning before sun-rise. In order to purify it from extraneous matter it is again liquified by the sun's heat, and passed through a strainer; it is then fit for use.

3. *P. lentiscus*. Lentisk. Mastic-tree. Leaves abruptly pinnate; leaflets lanceolate: rises to the height of eighteen or twenty feet, the trunk covered with a grey bark. May be propagated by laying down the young branches, which, if properly managed, put out roots, in a year, and may then be cut off from the old tree, and planted in separate pots. Gum mastic is obtained from this tree, by making transverse incisions into its bark, from which the mastic exudes in a fluid state.

PISTE, in the manage, the tread or track that a horse makes upon the ground he goes over. The language is, "This horseman observes the piste, and makes it his business to follow the tread;" that is, he follows his ground regularly, without enlarging or narrowing, without traversing or entangling: "such a horse works well upon two treads;" he works well with one piste.

PISTIA, in botany, a genus of the class monodelphia, order octandria. Calyx a tubular-hooded, tongue-shaped spathe: corolless; filament lateral; anthers from three to eight; style one; capsule one-celled, many-seeded. One species only; a native of Asia, Africa, America, and the West Indies; a stemless floating aquatic, with white axillary flowers.

PISTIL. The pointal of a plant. *Viscus fructui adhærens, pro pollinis receptione*. Philos. Bot. *Viscus interior e medulla. Organum genitale femineum*. Regn. Veg. A viscus or organ adhering to the fruit for the reception of the pollen. It is the fourth part of the fructification; and is supposed by Linnæus to be a continuation of the medulla or pith. Its appearance is that of a column or set of columns in the centre of the flower: and, when perfect, it consists of three parts. 1. Germen; the germ or ovary. 2. Stylus; the style. 3. Stigma.

PISTILLATION. *s.* (*pistillum*, Latin.) The act of pounding in a mortar (*Brown*).

PISTILLIFEROUS FLOWER. Having a pistil without stamens. Called a female flower by Linnæus.

PISTOIA, a considerable town of Tuscany, with a bishop's see. There are several fine

churches and magnificent palaces; but it is almost deserted in comparison to what it was formerly. It is seated at the foot of the Apennines, near the river Stella, 20 miles N.W. of Florence. Lon. 11. 29 E. Lat. 43. 55 N.

PISTOL. *s.* (*pistole, pistolet*, French.) A small hand-gun (*Clarendon*).

To PISTOL. *v. a.* (*pistoler*, French.) To shoot with a pistol.

PISTO'LE. *s.* (*pistole*, French.) A gold coin of many countries and many degrees of value.

PISTOLET. *s.* (diminutive of *pistol*.) A little pistol (*Donne*).

PISTON (*embolus*), in pump work, is a short cylinder of metal, or other solid substance, fitted exactly to the cavity of the barrel or body of the pump. There are two kinds of pistons used in pumps, the one with a valve, and the other without a valve, called a forcer; and each of these admits of a great variety.

PISUM. Pea. In botany, a genus of the class diadelphia, order decandria. Style triangular, carinate, with a sharp edge and downy on the upper side: two upper segments of the calyx shorter. Four species; all European plants, one indigenous to our own coasts.

1. *P. sativum*. Common pea. Petioles cylindrical; stipules rounded and crenate at bottom; peduncles many-flowered. There are four other varieties:

♂ Common marrowfat.

γ With the peas green.

δ With the husk eatable.

ζ With the flowers in umbels.

The subvarieties are almost innumerable, and it is impossible to allow space enough even to catalogue them. We shall therefore divide the more valuable of them into two sections of early and late.

Early Kinds.

Early golden hotspur.

Early Charlton hotspur.

Nichols's early golden hotspur.

Early Charlton.

Reading hotspur.

Masters's hotspur.

Ormsod's hotspur.

Early dwarf hotspur.

Leadman's dwarf.

Fan Spanish dwarf.

Early dwarf frame pea.

Pearl pea.

Cluster pea.

Royal green pea.

Essex hotspur.

Dwarf pea.

Sugar pea.

Late Kinds.

Spanish morotto.

Nonpareil.

Sugar dwarf.

Sickle pea.

Marrowfat.

Dwarf marrowfat.

Rose or crown pea.

Rounceval pea.

Long bearing pea.

Green field-pea.

White field-pea.

Pig pea.

As it is now the fashion to have peas very early, several of the former section are raised on hot-beds. The method of doing this is to sow the peas under warm hedges or walls, about the middle of October. When the plants are come up, their stalks are to be kept earthed up, and thus they are to remain till the beginning of February, covering them against the severe frost with pease-haulm, or other light covering. In January or February a moderate hot-bed must be made: the dung should be laid about two feet thick and carefully beat down, and covered about six inches deep with light fresh earth; and when the frames have been set on about four days the plants must be planted in the earth, at about a foot distance in rows, and placed in each row, at about two inches one from another. They must be watered and shaded till they have taken root, and then they must have as much air as possible; and when they begin to fruit, they must be watered more frequently than before, which will occasion their producing a larger quantity of fruit. The common dwarf pea is the sort always used on this occasion, as all the rest ramble too much in their stalks. The first sort of pea which should be sown to succeed those on the hot-beds is the hotspur, of which the gardeners reckon three or four subvarieties, which differ very little from each other; but that called the golden hotspur is usually preferred to the rest. These should be sown on warm borders in October, as those intended for the hot-bed, and treated every way in the same manner: but in spring these are subject to be destroyed by slugs and other vermin; the best method of destroying which is to slake a little lime, and throw over the earth among the plants. For fear of this crop miscarrying by the severity of weather, it is always proper to sow two others after this, at the distance of a fortnight each; and after this there should be no others sowed till the end of January; and after these there should be others at the beginning and end of February. To succeed these, which will supply the table with early pease, the Spanish morotto, which is a large pea, and a very plentiful bearer, should be sowed in rows on a clear plat of ground; the rows should be two feet and a half distant, and the pease dropt at an inch or two asunder: these must be all very carefully covered two inches deep with earth, and the rooks, mice, &c. prevented from getting at them. A fortnight after this, another spot should be sowed with this or some other large pea, and this continue every fortnight till the beginning of June.

The common white-pea succeeds best in a light land, somewhat rich: the time of sowing them is in the middle of April. Three bushels are the common allowance for an acre; and they kill the weeds a land is subject to, better

than any other crop. In Staffordshire they sow the garden rouncevals in fields, and they grow and yield very well, though they are left trailing upon the ground without any support of sticks. The white and rounceval pea are only to be sown with a broad cast, and harrowed in; but the common grey-pea, which is more frequently sown in fields than either of them, must be sown under furrow, and delights most in a cold wet clay; these are to be sown in February; and the common quantity of seed is two bushels to an acre. The blue pea is the best kind for light sandy land, and should be sown early. All peas love land manured with lime or marle, and should therefore be indulged in this propensity.

2. *P. arvense*. Petioles four-leaved; stipules crenate; peduncles one-flowered. This like the last is a native of Europe, and often cultivated, though less frequently for general use.

3. *P. maritimum*. English sea pea. Petioles flattish on the upper side; stem angular; stipule arrow-shaped; peduncles many-flowered. It is found wild upon the coast of Sussex, and in several other maritime counties; nearly allied to lathyrus.

4. *P. ochrus*. Yellow-flowered pea. Petioles decurrent, membranaceous, two-leaved; peduncles one-flowered. A native of Crete and Italy. The flowers are pale yellow, and small; pods two inches long: the peas may be eaten green, but unless gathered when very young they are coarse, and never so good as the common pea.

All these may be sown and managed as the common or garden pea.

PIT. *s.* (pic, Saxon; *pix*, Latin.) 1. A hole in the ground (*Bacon*). 2. Abyss; profundity (*Milton*). 3. The grave (*Psalms*). 4. The area on which cocks fight (*Hudibras*). 5. The middle part of the theatre (*Dryden*). 6. Any hollow of the body: as, *the pit of the stomach*; *the arm-pit*. 7. A dint made by the finger. 8. A mark made by a disease.

To PIT. *v. a.* 1. To press into hollows (*Sharp*). 2. To mark with hollows, as by the smallpox.

PITAPAT. *s.* (*patte, patte*, French.) 1. A flutter; a palpitation (*L'Estrange*). 2. A light quick step (*Dryden*).

PITCAIRNE (Archibald), an eminent physician, born at Edinburgh, 1652. After studying divinity and civil law, he chose physic and mathematics as his profession. He was for some time at Paris, and on his return excited the public attention by a small publication, in which he disputed the right of Harvey to the discovery of the circulation of the blood, which he asserted was fully known to Hippocrates. In 1692 he accepted the chair of professor of medicine at Leyden; but the next year returned to Scotland. He acquired here greater reputation by his pen than by his profession. His *dissertationes medicæ* appeared 1701, and were again edited 1713. He wrote besides some obscure Latin satirical poems, chiefly levelled against the friends of the revolution, which he by no means approved. He died 1713.

PITCAIRNIA, in botany, a genus of the

class hexandria, order monogynia. Calyx three-leaved, half superior; petals three with a nectariferous scale at the base of each: stigmas three, twisted; capsules three, bursting inwards; seeds winged. Three species; herbaceous plants of Jamaica, Santa Cruz, or India.

PITCAITLY WELLS, some remarkable saline springs, near Perth, in Scotland, deemed beneficial in scorbutic cases.

PITCH. *s.* (pic, Saxon; *pix*, Latin.) 1. The resin of the pine extracted by fire and inspissated (*Proverbs*). 2. (from *pic*, French. *Skinner*.) Any degree of elevation or height (*Shakspeare*). 3. Highest rise: not used (*Shakspeare*). 4. State with respect to lowness or height. 5. Size; stature (*Spenser*). 6. Degree; rate (*Denham*).

To PITCH. *v. a.* (*appicciare*, Italian.) 1. To fix; to plant (*Dryden*). 2. To order regularly (*Hooker*). 3. To throw headlong; to cast forward (*Shakspeare*). 4. To smear with pitch (*pico*, Latin. *Dryden*). 5. To darken (*Shakspeare*). 6. To pave (*Ainsworth*).

To PITCH. *v. n.* 1. To light; to drop (*Mortimer*). 2. To fall headlong (*Dryden*). 3. To fix choice (*Hudibras*). 4. To fix a tent or temporary habitation.

PITCH, in music, the acuteness or gravity of any particular sound, or of the tuning of any instrument. Any sound less acute than some other sound is said to be of a lower pitch than that other sound, and *vice versa*. The opera pitch is tuned above most others, and is therefore said to be higher than the common concert pitch.

PITCH. (*pix*.) *Pix sicca*. The juice of a species of fir, extracted by incision made in the bark of the tree. It is sometimes used as a detergent by surgeons. See PINUS.

PITCH (Burgundy). See BURGUNDY PITCH.

PITCH (Fossil). See PETROLEUM.

PITCH (Jews). See BITUMEN JUDAICUM.

PITCH TREE, in botany. See PINUS, in botany.

PITCHSTONE, in mineralogy, a species of opal. See OPALUS.

PITCHER. *s.* (*pitcher*, French.) 1. An earthen vessel; a water pot (*Shakspeare*). 2. An instrument to pierce the ground in which any thing is to be fixed (*Mortimer*).

PITCHER-SHAPED. *Urceolatus*. Swelling or bellying out like a pitcher. Applied to the calyx, corolla, and nectary.

PITCHFORK. *s.* (*pitch* and *fork*.) A fork with which corn is pitched or thrown upon the waggon (*Swift*).

PITCHINESS. *s.* (from *pitchy*.) Blackness; darkness.

PITCHING, in naval affairs, is the vertical vibration which the length of a ship makes about her centre of gravity, or the motion by which she plunges her head and after part alternately into the hollow of the sea. This motion may proceed from the waves that agitate the vessel, or the wind acting upon the sails, which makes her stoop at every blast.

PITCH-PIPE, in music, an instrument

used by vocal practitioners to ascertain the pitch of the key in which they are about to sing. It is blown at one end, like a common flute, and being shortened or lengthened by a graduated scale, is capable of producing with mechanical exactness all the semitonic degrees within its compass.

PITCHY. *a.* (from *pitch*.) 1. Smeared with pitch. (*Dryden*). 2. Having the qualities of pitch. (*Woodward*). 3. Black; dark; dismal. (*Prior*).

PITCOAL. *s.* (*pit* and *coal*.) See **COAL** and **COLLIERY**.

PITEOUS. *a.* (from *pity*.) 1. Sorrowful; mournful; exciting pity. (*Shakspeare*). 2. Compassionate; tender. (*Prior*). 3. Wretched; paltry; pitiful. (*Milton*).

PITEOUSLY. *ad.* (from *piteous*.) In a piteous manner. (*Shakspeare*).

PITEOUSNESS. *s.* (from *piteous*.) Sorrowfulness; tenderness.

PITFALL. *s.* (*pit* and *fall*.) A pit dug and covered, into which a passenger falls unexpectedly. (*Sandys*).

PITH. *s.* (*pitte*, Dutch.) 1. The marrow of the plant; the soft part in the midst of the wood. (*Bacon*). 2. Marrow. See **MARROW** and **MEDULLA**. 3. Strength; force. (*Shaks.*). 4. Energy; cogency; fulness of sentiment; closeness and vigour of thought and style. 5. Weight; moment; principal part. (*Shakspeare*). 6. The quintessence; the chief part. (*Shaks.*).

PITHEA, a seaport of Sweden, in W. Bothnia, seated on a small island, at the mouth of the Pithea, in the gulf of Bothnia. It is joined to the continent by a wooden bridge, and is 80 miles S.W. of Tornea. Lon. 22. 40 E. Lat. 65. 11 N.

PITHECUSA, a small island on the coast of Etruria, anciently called *Ænaria* and *Inarina*, with a town of the same name on the top of a mountain. Some suppose that it received its name from *πῑθηκοί*, monkeys, into which the inhabitants were changed by Jupiter.

PITHILY. *ad.* (from *pithy*.) With strength; with cogency; with force.

PITHINESS. *s.* (from *pithy*.) Energy; strength. (*Spenser*).

PITHESS. *a.* (from *pith*.) 1. Wanting pith; wanting strength. (*Shakspeare*). 2. Wanting energy; wanting force.

PITHO, the goddess of persuasion among the Romans, supposed to be the daughter of Mercury and Venus.—2. A Roman courtesan, who received this name on account of the allurements which her charms possessed, and of her winning expressions.

PITHOU (Peter), a Frenchman, born at Troyes, 1539. He studied under Turnebus and Cujacius, and became distinguished at the bar as an eloquent civilian. He escaped with difficulty the slaughter of St. Bartholomew, and immediately embraced the Romish faith. He visited England with Montmorency, and so great was his character that the duke of Tuscany referred some intricate points to his impartial decision, and the third and fourth Henries employed his abilities, not only to

oppose the league, but to support the Gallican church against the Roman pontiff. Pithou died on his birth-day, 1596. He published some valuable works on law, history, and classical literature, and to his industry we are indebted for the discovery of Phædrus, of the novella of Justinian, and other books buried in obscurity. The best known of his works are treatise on the liberties of the Gallican church, 4 vols. fol.—Notes on authors, &c.

PITHOU (Francis), brother of Peter, was procureur general of the chamber of justice under Henry IV. against the financiers, and afterwards was admitted into the king's council. He discovered the fables of Phædrus, which he published with his brother. He published of his own a comparison of the law of the Romans with those of Moses, 12mo.—an edition of the Salique law with notes—treatise on the greatness and the rights of the French monarchy, 8vo.—an edition of comes theologus—observations ad codicem, fol.—antiqui rhetores Latini Rutulius Lupus, Aquila Romanus, &c. He died 1621.

PITHY. *a.* (from *pith*.) 1. Consisting of pith. (*Philips*). 2. Strong; forcible; energetic. (*Addison*).

PITIABLE. *a.* (*pitoyable*, Fr. from *pity*.) Deserving pity. (*Atterbury*).

PITIABLENESS. *s.* (from *pitiable*.) State of deserving pity. (*Kettlewell*).

PITIFUL. *a.* (*pity* and *full*.) 1. Melancholy; moving compassion. (*Spenser*). 2. Tender; compassionate. (*Shakspeare*). 3. Paltry; contemptible; despicable. (*Dryden*).

PITIFULLY. *ad.* (from *pitiful*.) 1. With pity; with compassion. (*Com. Pr.*). 2. Mournfully; in a manner that moves compassion. (*Tillotson*). 3. Contemptibly; despicably. (*Clarrissa*).

PITIFULNESS. *s.* (from *pitiful*.) 1. Tenderness; mercy; compassion. (*Sidney*). 2. Despicableness; contemptibleness.

PITILESSLY. *ad.* (from *pitiless*.) Without mercy.

PITILESSNESS. *s.* Unmercifulness.

PITILESS. *a.* (from *pity*.) Wanting pity; wanting compassion; merciless. (*Fairfax*).

PITISCUS (Samuel), of Zutphen, 1637, studied at Deventer and Groningen, and was elected master of the school at Zutphen, and afterwards obtained the direction of the college of Jerome at Utrecht, where he died 1717. He was author of several learned works, lexicon Latino Belgicum, 4to.—lexicon antiquitatum Romanarum, fol.—besides an edition of Rufinus' Rom. antiquities—editions of Suetonius, Q. Curtius, Aurelius Victor, &c.

PITISCUS (Bartholomew), author of thesaurus mathematicus, fol. and of a treatise on trigonometry, died 1613.

PITMAN. *s.* (*pit* and *man*.) He that in sawing timber works below in the pit. (*Moxon*).

PITOT (Henry), of a noble family in Languedoc, was born at Aramont in the diocese of Uzés, on the 29th of May 1695, and died there on the 27th of December, 1771, aged 76. He learned the mathematics without a master, and

went to Paris in 1718, where he formed a close friendship with the illustrious Reaumur. In 1724, he was admitted a member of the Royal Academy of Sciences at Paris, and in a few years rose to the degree of a pensioner. Besides a vast number of memoirs printed in the collection of that society, he published in 1731 the *Theory of the Working of Ships*, in one volume 4to; a work of considerable merit, which was translated into English, and made the author be admitted into the Royal Society of London. In 1740, the states-general of Languedoc made choice of him for their chief engineer, and gave him at the same time the appointment of inspector-general of the canal which unites the two seas. That province is indebted to him for several monuments of his genius, which will transmit his name with lustre to posterity. The city of Montpellier being in want of water, Pitot brought from the distance of three leagues two springs which furnish a plentiful supply of that necessary article. They are brought to the magnificent Place du Peyron, and thence are distributed through the city. This astonishing work is the admiration of all strangers. The illustrious Marshal de Saxe was the great patron and friend of Pitot, who had taught this hero the mathematics. In 1754, he was honoured with the order of St. Michael. In 1735 he married Maria-Leonina Pharambier de Sabballoua, descended from a very ancient noble family of Navarre. By this marriage he had only one son, who was first advocate-general of the court of accounts, aids, and finances of Montpellier. Pitot was a practical philosopher, and a man of uncommon probity and candour. He was also a member of the Royal Society of Sciences of Montpellier; and his eulogium was pronounced in 1772, by M. de Ratte, perpetual secretary, in presence of the states of Languedoc; as it likewise was at the Royal Academy of Sciences at Paris, by Abbé de Fouchi, who was then secretary.

PITS or PITSEUS (John), an English biographer, born at Alton, 1560, and educated at Winchester and New college, Oxford. He went to Douay, Rheims, and to Rome, where he studied seven years, and became a priest. By the patronage of cardinal Lorraine he obtained a canonry at Verdun, and afterwards was confessor to the duchess of Cleves for twelve years. He next was made dean of Verdun, where he died 1616. He wrote an useful work collected from English history, containing the lives of the kings, bishops, apostolical men, and writers of England, in 4 large vols. but of these only part was published under the title of *de illustribus Angliæ scriptoribus*, &c.

PITSAW. *s.* (*pit* and *saw*.) The large saw used by two men, of whom one is in the pit (*Moxon*).

PITT (Christopher), an English poet, born at Blandford, 1699, and educated at Winchester school. When chosen to college he presented to his electors a poetical translation of Lucan's *Pharsalia*, which unfortunately is not

now extant. In 1722 he obtained the living of Pimpurn, Dorsetshire, and closed a life of benevolence and virtue, 1748, and was buried at Blandford, where a stone records the candor and simplicity of his manners, and asserts that he lived innocent and died beloved. He is chiefly known as the author of an eloquent translation of the *Æneid*, which rivals Dryden's, but of which it may be said, that while Pitt pleases the critic, Dryden charms the people, and that Pitt is quoted while Dryden is read. He also translated Vida's art of poetry, and wrote some poems, &c.

PITT (William), earl of Chatham, an illustrious statesman, born 15th Nov. 1708. His grandfather was the governor of Madras, who purchased for 20,400l. a celebrated diamond, weighing 127 carats, which received the name of Regent, because sold to the regent of France for 135,000l. The young statesman was educated at Eton, and in 1726 he entered at Trinity college, Oxford, which he left for the military profession. In 1735 he was elected into parliament for Old Sarum, and enlisted early in the ranks of opposition against Walpole; and in his speeches against the Spanish convention, and against the bill for registering seamen, displayed such acuteness, vehemence, and depth of argumentation, as astonished the house, and marked him as worthy of the highest offices of the state. The duchess of Marlborough, applauding the patriotism of the young orator, left him in her will a legacy of 10,000l. for defending, as she said, the laws of his country. In 1746, in the administration which had succeeded Walpole, he became joint vice-treasurer of Ireland, and soon after treasurer and paymaster of the army, and privy counsellor. In 1755 he resigned; but though the next year he received the seals of secretary of state, he did not continue long in office; but the public voice accompanied him in his retirement, and in June, 1757, he was reinstated in his office. His restoration to power was a new era of splendid conquests, and of national glory. England proved every where successful in consequence of his judicious plans. Quebec was conquered, and the French were defeated in Africa and in the East. The death of George II. and the accession of George III. was soon followed by the resignation of the minister, who refused to co-operate with an administration, which by the influence of lord Bute, as it is supposed, thwarted his vigorous measures. His retirement was attended by the grant of a peerage to his lady, and a pension of 3000l. His censured the peace of 1763, declaring that England from the extent of her victories was entitled to more solid advantages. He afterwards remained silent till the question of general warrants, in 1764, called forth all his eloquence, and the keenness of his satire against those unpopular engines of arbitrary power. In 1766 he accepted the privy seal, and an earldom; but he resigned the office, Nov. 1768. His health now declined, and a hereditary gout undermined his constitution, without,

however, diminishing the energetic powers of his mind. In the American war he burst forth from his retirement, and, in the house of lords, deprecated severe measures against the colonists. On one of these occasions, after the duke of Richmond had replied to him, the venerable peer rose up to answer the speech, but his debilitated constitution sunk under the attempt, and he fell in a fit into the arms of those who were near him. This event, which exhibited a favourite statesman breathing his last, whilst he uttered the most animated sentiments for the glory and the independence of his country, happened 8th of April, 1778, and he died on the ensuing 11th of May. All parties now united to pay due respect to his memory. A public funeral and a monument in Westminster abbey, at the expence of the nation, were immediately voted by parliament, as a testimony, as the inscription records, to the virtues and abilities of a man, during whose administration divine providence had exalted Great Britain to a height of prosperity and glory unknown to any former age. As a statesman, says his biographer, lord Chatham was born with all the graces of the orator, and possessed every requisite to bespeak respect and even awe. A manly figure and penetrating look fixed attention and commanded reverence, and the keen lightening of his eye spoke the high spirit of his soul, even before the lips had begun utterance. The most fluent and ready orators have shrunk back appalled from his all-powerful eloquence. He had not indeed the correctness of language so striking in the great Roman orator, but he had the *verba ardentia*, the bold, glowing words, which darted with such irresistible efficacy, that Walpole, surrounded with power and the unshaken support of a decided majority, never heard his voice in the house of commons without being alarmed and thunder-struck. Letters from lord Chatham to his nephew were published a few years ago by lord Grenville.

PITT (William), a celebrated statesman, second son of the preceding, was born at Hayes, 28th May, 1759. From his earliest years he was instructed by his father, who foresaw his future greatness, and taught him to argue with logical precision, and to speak with elegance and force. Under the tuition of the Rev. Mr. Wilson, and at Pembroke hall, Cambridge, under Dr. Turner, and Dr. Pretzman, he matured his knowledge of classical literature, and of mathematics, and he left the university with the degree of M. A. and a high character for application and for abilities. He then entered at Lincoln's-inn, and went once or twice on the western circuit, where he was occasionally employed as junior counsel. At the first general election he was proposed for Cambridge university, but few seconded his pretensions; and the next year he obtained a seat for Appleby. He enlisted against lord North and the American war; and his first speech in support of Mr. Burke's bill displayed that commanding eloquence

VOL. IX.

which many of the members had before so warmly applauded in his father. His first motion was for the more equal representation of the people in parliament; and though it was lost by a small majority, it rendered him a popular member in the commons. On the death of lord Rockingham, he accepted, at the age of 22, the office of chancellor of the exchequer; and under this administration the American war was concluded. Though he ably defended his colleagues, the peace was regarded by the majority of the nation as unpopular, and the ministry was dissolved. Restored to privacy, Mr. Pitt passed some months on the continent; and on the dismissal of the coalition administration, he was selected for the office of first lord of the treasury, and chancellor of the exchequer, 18th December, 1783. Thus, at the head of affairs, he bent the great powers of his mind to the framing of a bill for the regulation of India affairs, less objectionable than that of Mr. Fox. His attempts were at first unavailing, as his predecessors retained their influence in the commons; and in consequence of this struggle between the house and the king's prerogative, an appeal was made to a new parliament. The new parliament not only approved of his India bill, but adopted his system for the reduction of the national debt by a sinking fund, and cemented his commercial treaty with France. During the king's unfortunate illness, in 1788, Mr. Pitt boldly resisted the right of the prince of Wales to assume the government, which Mr. Fox, with more warmth than constitutional knowledge, had hastily asserted. The murder of the French king, and the ambitious views of the rulers of France, were productive of disputes with England, and war was declared in 1793. During hostilities for eight years, in situations where all precedents were unavailing, and all the political principles of former times disregarded, the premier conducted the affairs of the nation with that manly energy which future historians will celebrate to his honour. He planned, in 1800, the union with Ireland. He soon after retired from the head of affairs, in consequence of disputes with respect to the catholic emancipation; but more probably to make room for an administration which might, with greater probability of success, negotiate a peace with France. The insidious peace of Amiens, under the administration of Mr. Addington, met with the approbation of Mr. Pitt, as the most advantageous which the situation of the continent, and the gigantic power of France could allow, and in 1804 he was again replaced at the head of affairs. Difficulties, however, surrounded him on all sides; many of his old colleagues had joined the ranks of opposition, and not a few condemned the method by which he had regained his ascendancy in the king's councils. Unappalled by the dangers which threatened his country, he formed that powerful confederacy with Russia and Austria, which, had it been better conducted by the generals of the belligerent powers, might have checked, if not crushed,

E E

the colossal influence of France. In the mean time, while public affairs assumed the most threatening aspect, a hereditary gout weakened the delicate constitution of the minister, and the seeds of the illness under which he laboured in 1802, and which had never been completely eradicated, produced the most alarming debility in the nervous system. Excessive anxiety, application to business, and besides, a constant privation of rest, contributed to the general breaking up of his constitution, and the intelligence of the disasters at Austerlitz, and the failure of his favourite plan for the deliverance of Europe from French tyranny, hastened his end. He expired at his house at Putney, Surrey, on the 23d January, 1806, and the last words which quivered on the dying lips of this extraordinary man were, Oh, my country! By a vote of the commons, his remains were buried in Westminster abbey, at the public expence, and the heart of every lover of patriotism assents to the truth of the emphatical words which the herald pronounced after the corpse had descended to the tomb; *non sibi sed patriæ vivit*. By the same vote of the commons, his debts were discharged by the public; and it is not a small proof of his great disinterestedness, that, during a long administration of above 20 years, he not only did not accumulate riches, but died insolvent. To appreciate the character of Mr. Pitt is no easy task. We shall adopt part of an account (which in the main we believe to be very just) of Mr. John Gifford; and for a more enlarged view of Mr. Pitt's varied talents, refer to the account of Mr. Gifford's book in No. 7. of the Quarterly Review.

As a statesman, the resources, as well as the firmness, of Mr. Pitt's mind have been amply demonstrated by the measures which he adopted, to meet the various and unforeseen difficulties with which this nation was surrounded, during the period of his administration. Abroad, he had to struggle with the most gigantic power which ever raised its head in opposition to his country; while at home, he had to support at the same time commercial and national credit, to allay the spirit of mutiny, to extinguish the flames of rebellion, to provide for the importunate calls of famine. The energies of his mind were most eminently exerted upon those important occasions; so that, in spite of internal distractions, he carried the power of the nation to a greater height than it had attained even under the administration of his father.

As a parliamentary orator, his powers were various. In statement he was perspicuous, in declamation animated. If he had to explain a financial account, he was clear and accurate. If he wanted to rouse a just indignation for the wrongs of the country, he was rapid, vehement, glowing, and impassioned. And whether his discourse was argumentative or declamatory, it always displayed a happy choice of expression, and a fluency of diction, which could not fail to delight his hearers. So singularly select, felicitous, and appropriate was his language, that

it has often been remarked, a word of his speech could scarcely be changed without prejudice to its harmony, vigour, or effect. He admired much in Mr. Fox, the happy effect with which he illustrated his arguments, by the application of well-known anecdotes, or by passages from modern authors; but he did not imitate him in this respect: on the other hand, he used to condemn his habit of repetition.

Mr. Pitt's love of amplification has been sometimes urged as detracting from his excellence as an orator; but it was his own remark, that every person who addressed a public assembly, and was anxious to be distinctly understood, and to make an impression upon particular points, must either be copious upon those points, or repeat them, and that, as a speaker, he preferred copiousness to repetition. Of his eloquence, it may be observed generally, that it combined the eloquence of Tully with the energy of Demosthenes. It was spontaneous; always great, it shone with peculiar, with unequalled splendour, in a reply, which precluded the possibility of previous study; while it fastened the imagination by the brilliancy of language, it convinced the judgment by the force of argument; like an impetuous torrent, it bore down all resistance: extorting the admiration even of those who most severely felt its strength, and who most earnestly deprecated its effect.

PITTACUS, a native of Mitylene in Lesbos, was one of the seven wise men of Greece. His father's name was Hyrradius. He delivered his country from the oppression of the tyrant Melanchrus, and in the war which the Athenians waged against Lesbos, he killed Phrynon, the enemy's general, by entangling him in a net. He was amply rewarded for this victory; his countrymen unanimously appointed him governor of their city with unlimited authority. In this capacity, Pittacus behaved with great moderation, and after he had established and enforced the most salutary laws, he voluntarily resigned the sovereign power, after he had enjoyed it for ten years, observing, that the virtues and innocence of private life were incompatible with the power and influence of a sovereign. He died in the 82d year of his age, about 570 years before Christ, after he had spent the last ten years of his life in literary ease and peaceful retirement. Many of his maxims were inscribed on the walls of Apollo's temple at Delphi. By one of his laws, every fault committed by a man when intoxicated deserved double punishment.

PITTANCE. *s.* (*pitance*, Fr. *pietantia*, Ital.) 1. An allowance of meat in a monastery. 2. A small portion (*Shakspeare*).

PITTED LEAF. See LACUNOSUS.

PITTENWEEM, a seaport in Fifeshire, at the entrance of the frith of Forth, 23 miles N.E. of Edinburgh. Lon. 2. 49 W. Lat. 56. 12 N.

PITTHRUS, a king of Trœzene in Argolis, son of Pelops and Hippodamia, universally admired for his learning and wisdom. He gave his daughter Æthia in marriage to Ægeus, king

*Pontederia Cordata.**Heart-leaved Pontederia.**Pittosporum Tobira.**Glossy-leaved Pittosporum.*

of Athens, and he himself took particular care of the education of his grandson Theseus. He was buried at Trœzene, and on his tomb was seen, for many ages, three seats of white marble, on which he sat with two other judges, whenever he gave laws to his subjects.

PITTOSPORUM, in botany, a genus of the class pentandria, order monogynia. Calyx deciduous; petals five, forming a tube; capsule from two to five-valved; seeds covered with a pulp. There is but one species that really belongs to this genus, though several are by some botanists erroneously ranked under it: *P. coriaceum*; a tree of the Canaries with oblong blunt leaves; peduncles solitary, many-flowered; flowers on umbelled pedicels. See Nat. Hist. Pl. CXL.

PITTSBURGH, or **FORT PITT**, a flourishing town of Pennsylvania, capital of the county of Allegany, situated on the W. side of the Allegany mountains, on a point of land between the rivers Allegany and Monongahela. Here was the French fort du Quesne; in an expedition against which, in 1756, general Braddock fell into an ambuscade, and was defeated and slain. This fort was abandoned by the French, in 1758, on the approach of general Forbes; and its name was changed to that of Pitt, in honour to the minister by whom the war was then directed. At this place the Allegany takes the name of Ohio. It is 320 miles W. of Philadelphia. Lon. 79. 48 W. Lat. 40. 26 N.

PITUITA. (*pituita*.) Phlegm, or viscid and glutinous mucus.

PITUITARY GLAND. *Glandula pituitaria*. In anatomy, a gland situated within the cranium, between a duplicature of the dura mater, in the sella turcica of the sphenoid bone.

PITUITARY MEMBRANE. *Membrana pituitaria*. In anatomy. Schneiderian membrane. The mucus membrane that lines the nostrils and sinuses, communicating with the nose, is so called, because it secretes the mucus of those parts, to which the ancients have assigned the name of pituita.

PITUITOUS. *a. (pituitosus*, Latin; *pituiteux*, French.) Consisting of phlegm (*Arbuthnot*).

PITY. *s. (pitie*, Fr. *pieta*, Italian.) 1. Compassion; sympathy with misery; tenderness for pain or uneasiness (*Calamy*). 2. A ground of pity; a subject of pity or of grief (*Bacon*).

To PITY. *v. a. (pitoyer*, French.) To compassionate misery; to regard with tenderness on account of unhappiness (*Addison*).

To PITY. *v. n.* To be compassionate (*Jerem.*).

PITYOCAMPASIS. See **BOMBYX**.

PITYRIASIS. (*πυτυρίασις*, from *πυτυρον*, bran, so named from its branny like appearance.) A genus in the second order, or scaly diseases, of Dr. Willan's cutaneous diseases. The pityriasis consists of irregular patches of small thin scales, which repeatedly form and separate, but never collect into crusts, nor are attended with redness or inflammation, as in

the lepra and scaly tetter. Dr. Willan distinguishes pityriasis from the porrigo of the Latins, which has a more extensive signification, and comprehends a disease of the scalp, terminating in ulceration; whereas the former is, by the best Greek authors, represented as always dry and scaly. Thus, according to Alexander and Paulus, pityriasis is characterised by "the separation of slight furfuraceous substances, from the surface of the head, or other parts of the body, without ulceration." Their account of this appearance is conformable to experience; and the two varieties of it which they have pointed out may be denominated pityriasis capitis, and pityriasis versicolor. Pityriasis capitis, when it affects very young infants, is termed by nurses the dandriff. It appears at the upper edge of the forehead and temples, as a slight whitish scurf set in the form of a horse-shoe; on other parts of the head there are large scales, at a distance from each other, flat, and semipellucid. Sometimes, however, they nearly cover the whole of the hairy scalp, being close together, and imbricated. A similar appearance may take place in adults; but it is usually the effects of lepra, scaly tetter, or some general disease of the skin.

Elderly persons have the pityriasis capitis in nearly the same form as infants; the only difference is, that this complaint in old people occasions larger exfoliations of the cuticle.

The pityriasis versicolor chiefly affects the arms, breasts, and abdomen. It is diffused very irregularly; and being of a different colour from the usual skin colour, it exhibits a singular chequered appearance. These irregular patches, which are at first small, and of a brown or yellow hue, appear at the scrobiculus cordis, about the mammæ, clavicles, &c. Enlarging gradually, they assume a tessellated form; in other cases they are branched, so as to resemble the foliaceous lichens growing on the bark of trees; and sometimes, when the discolouration is not continuous, they suggest the idea of a map being distributed on the skin like islands, continents, peninsulas, &c. All the discoloured parts are slightly rough, with minute scales, which soon fall off, but are constantly replaced by other. This scurf, or scalliness, is most conspicuous on the sides and epigastric region. The cuticular lines are somewhat deeper in the patches than on the other contiguous parts; but there is no elevated border, or distinguishing boundary between the discoloured part of the skin, and that which retains its natural colour. The discolouration rarely extends over the whole body. It is strongest and fullest round the umbilicus, on the breasts, and sides; it seldom appears in the skin over the sternum, or along the spine of the back. Interstices of proper skin colour are more numerous, and largest at the lower part of the abdomen and back, where the scales are often small, distinct, and a little depressed. The face, nates, and lower extremities are least affected; the patches are found upon the arms, but mostly on the inside, where they are distinct and of different sizes.

The pityriasis versicolor is not a cuticular disease; for when the cuticle is abraded from any of the patches, the sallow colour remains as before in the skin or retenuosum. This singular appearance is not attended with any internal disorder, nor with any troublesome symptom, except a little itching or irritation felt on getting into bed, and after strong exercise, or drinking warm liquors. There is in some cases a slight exanthema, partially distributed among the discoloured patches; and sometimes an appearance like the lichen pileus; but eruptions of this kind are not permanent, neither do they produce any change in the original form of the complaint. The duration of the pityriasis versicolor is always considerable. Dr. Willan has observed its continuance in some persons for four, five, or six years. It is not limited to any age or sex. Its causes are not pointed out with certainty. Several patients have referred it to fruit taken in too great quantities; some have thought it was produced by eating mushrooms; others by exposure to sudden alterations of cold and heat. In some individuals, who had an irritable skin, and occasionally used violent exercise, the complaint has been produced, or at least much aggravated, by wearing flannel next to the skin. It is likewise often observed in persons who had resided for a length of time in a tropical climate.

PIU. (Ital.) In music, a word of augmentation: as *piu presto*, quicker. *Piu piano*, more soft.

PIVA. A hautboy or cornet.

PIVOT, a foot, shoe, or extremity of iron, or other metal, usually conical, or terminating in a point, whereby a body intended to turn round bears on another fixed at rest, and performs its circumvolutions. The pivot usually bears or turns round in a sole, or piece of iron or brass hollowed to receive it.

PIURA, a town of Peru, capital of a jurisdiction of the same name. This was the first Spanish settlement in Peru, and was founded in 1531. It is 25 miles S.S.E. of Patia. Lon. 81. 0 W. Lat. 5. 55 S.

PIUS I. a pope and saint, succeeded Hyginus in 142. He was an Italian by birth, and suffered martyrdom in 157. He condemned the heresies of Valentinian.

PIUS II. (Ænea Sylvius Piccolomini), born in 1405, at Corsini in Sienna. In 1431 he became secretary to cardinal Dominic Capranica at the council of Basil, and acted in the same capacity to cardinal Albergotti, who sent him to Scotland to negotiate a peace between England and that country. On his return from this mission he was at the council of Basil, which he zealously defended against the authority of the popes. He was employed in several embassies, in which he shewed great dexterity. After obtaining some distinguished preferences, he was made a cardinal in 1456, and two years afterwards elected pope on the death of Calixtus III. On his promotion to this dignity he issued a bull, in which he retracted all that he had said and done with respect to the council of Basil. He behaved with great spirit

in his high office, and received ambassadors from the patriarchs of the east, who made their submission to the papal chair. Pius died in the midst of great preparations which he was making for a war with the Turks in 1464. His works were printed at Basil in 1551, folio.

PIUS III. (Francis Thodeschini), son of a sister of Pius II. succeeded Alexander VI. in the papal chair; but was suddenly snatched away 21 days after his election, 1503.

PIUS IV. (John Angelo, cardinal de Medicis), of Milan, was employed by Clement VII. in several embassies, and succeeded to the papedom, 1559. He re-established the council of Trent, and affirmed its decrees by a bull. He died 1565, aged 66.

PIUS V. (Michael Ghisleri), of Bosco, embraced the Dominican order. He was elected pope after Pius IV. 1566; but though he attempted to reform the morals of his church, and to correct abuses, his measures frequently degenerated into severity. His publication of the bull called *In Cæna Domini*, by which he attempted to enforce the superior jurisdiction of the papal see in temporal affairs, raised him many enemies. He joined the Spaniards and Venetians against the Turks, and under his auspices the famous battle of Lepanto was fought, 1571. He died of the stone 1572, aged 68, and was regarded as so formidable that Selim noticed his death by three days of public rejoicings.

PIUS VI. (John Angelo Braschi), was born at Cesena, 1717. He was made treasurer of the apostolic chamber, and raised to the rank of cardinal by Ganganelli, whom he succeeded as pope, 1775. His reign was one of the longest, and likewise one of the most unfortunate in the Roman history, and some assert, that in his pontificate was fully verified the Latin adage:

Semper sub Sextis perdita Roma fuit.

His government was marked by popular measures; he repressed abuses, and completed the noble museum of the Vatican, begun by his predecessor, by the collection of vases, medals, statues, and monuments. Of this treasure a magnificent account, with engravings, has appeared in 6 vols. folio. The port of Ancona was also repaired and embellished, and the Pontine marshes were drained of their pestilential waters. Canals were constructed to drain the marshes, the Appian way was repaired, or rather a new road was built 40 miles in length, with rows of poplars, and houses were erected for the convenience of travellers. In his character Pius was mild, and in his conduct hospitable; and Joseph II. of Germany, Paul of Russia, and other princes, were witnesses of his kindness and of his virtues. As the head of the church, Pius naturally disapproved of the French revolution, which seized or devoted all ecclesiastical establishments, and he embraced the cause of the allies. He received with kindness the banished priests, and this drew upon him the vengeance of the French rulers. Buonaparte was directed to attack the Roman states, and after taking Urbino, Bologna, An-

cona, &c. he offered peace to the sovereign pontiff, on condition of his paying a large sum of money, and of sending to Paris the choicest pieces in painting and sculpture at Rome. A reconciliation thus tyrannically effected proved not of long duration. The French ambassador was insulted and murdered by the populace, and in consequence the ecclesiastical territories were invaded. Rome was taken by the orders of Bonaparte, and the captive pope a prisoner in his palace, was conveyed amidst the insults of the French soldiery, first to Sienna, and afterwards across the Alps into France. At Briancon he converted the ferocity of his oppressors into admiration and reverence, and when he expected to be murdered by them, he saw the enraged multitude suddenly moved with compassion and fall down at his feet. From Briancon he passed on to Valence, where he was permitted to rest. Here his sufferings were completed; after an illness of 11 days from fatigue and old age, he died 29th August, 1798, aged 82. His remains were buried at Valence by order of Buonaparte; but afterwards they were removed to Rome in 1802, with great funeral pomp. This prelate, so well known by his misfortunes, was possessed of many virtues, and the humility and meekness with which he endured the indignities of his persecutors entitled him to universal veneration.

PIX. *s.* (*pixis*, Lat.) A little chest or box, in which the consecrated host is kept in Roman catholic countries (*Hanmer*).

PIX LIQUIDA. Vegetable tar. This tar is produced from the *pinus sylvestris* of Linneus, (*pinus foliis geminis rigidis, conis ovato-conicis longitudine foliorum subgeminis basi-rotundatis*. C. O. Monoecia, monadelphica), by cutting it into pieces, which are enclosed in a large oven constructed for the purpose. It is well known for its economical uses. Tar water, or water impregnated with the more soluble parts of tar, was some time ago a very fashionable remedy in a variety of complaints, but is in the present practice fallen into disuse.

PIZARRO (Francis), the conqueror of Peru, was the illegitimate son of a gentleman by a woman of low condition, and born at Truxillo. Though obliged to keep hogs for his support, he possessed an undaunted courage, and embarked for America. In 1524, fired with the love of glory, he united with Almagro and Lucque to go in quest of new undiscovered countries. After incredible hardships, he penetrated into Peru, 1531, where he seized the monarch Atahualpa, and afterwards cruelly put him to death. The possession of an opulent kingdom, and the submission of the inhabitants, did not inspire the Spaniards with the love of ease, but produced quarrels, and Almagro and Pizarro met in arms 1538. Almagro was defeated and put to death; but the son and the friends of the fallen chief united against their oppressor, and Pizarro was assassinated, after making an obstinate resistance, 26th June, 1541. This bold ad-

venturer, who knew not even how to read, was fully formed for command. He laid the foundations of Lima, and might deserve the name of a hero, were not perfidy and cruelty indelible stains on his character.

PIZZI (Joachim), of Rome, was in 1759 director of the academy of Arcades. He possessed genius as a poet, and vigour and correctness as a writer. His works are the vision of Eden, a poem in 4 cantos—the triumph of poetry, a poem—dissertation on an antique cameo, &c. He died 1790, aged 74.

PIZZICATO. (*Ital.*) An expression particularly applicable to violin music, and implying that the movement, or the passage over which it is written, is to be performed by the fingers instead of the bow.

PIZZIGHETONE, a town of Italy, in the Cremonese, with a strong castle in which Francis I. of France was kept prisoner. It was taken by the French in 1796, and retaken by the Austrians and Russians in 1799. It is situate on the Adda, nine miles N.W. of Cremona, and 13 S.E. of Lodi. Lon. 9. 53 E. Lat. 49. 50 N.

PIZZLE. *s.* (quasi *pissle*. *Minshew.*) The part in animals official to urine and generation (*Bacon*).

PLACABILITY. **PLA'CABLENESS.** *s.* (from *placable*.) Willingness to be appeased; possibility to be appeased.

PLA'CABLE. *a.* (*placabilis*, Latin.) Willing or possible to be appeased (*Milton*).

PLACARD. **PLACA'RT.** *s.* (*placard*, French.) An edict; a declaration; a manifesto.

To PLA'CATE. *v. a.* (*placeo*, Latin.) To appease; to reconcile (*Forbes*).

PLACE. *s.* (*place*, French.) 1. Particular portion of space (*Addison*). 2. Locality; ubiquity; local relation (*Locke*). 3. Local existence (*Revelation*). 4. Space in general (*Davies*). 5. Separate room (*Shakspeare*). 6. A seat; residence; mansion (*John*). 7. Passage in writing (*Bacon*). 8. Ordinal relation (*Addison*). 9. State of actual operation; effect (*Dryden*). 10. Existence; state of being (*Swift*). 11. Rank; order of priority (*Sh.*). 12. Precedence; priority (*Ben Jonson*). 13. Office; public character or employment (*Knolles*). 14. Room; way; space for appearing or acting given by cession (*Dryden*). 15. Ground; room (*Hammond*). 16. Station in life (*Duty of Man*).

To PLACE. *v. a.* (*placer*, French.) 1. To put in any place, rank, condition, or office (*Milton*). 2. To fix; to settle; to establish (*Locke*). 3. To put out at interest (*Pope*).

PLACE, in philosophy, that part of infinite space which any body possesses.

Aristotle and his followers divide place into external and internal.

Internal place, is that space or room which the body contains. And

External place, is that which includes or contains the body; and is by Aristotle called the first or concave and immoveable surface of the ambient body.

Newton better, and more intelligibly, distinguishes place into absolute and relative.

Absolute and primary place, is that part of infinite and immovable space which a body possesses. And

Relative, or secondary place, is the space it possesses considered with regard to other adjacent objects.

Dr. Clarke adds another kind of relative place, which he calls relatively common place; and defines it, that part of any moveable or measurable space which a body possesses; which place moves together with the body.

Place, Mr. Locke observes, is sometimes likewise taken for that portion of infinite space possessed by the material world; though this, he adds, were more properly called extension. The proper idea of place, according to him, is the relative position of any thing, with regard to its distance from certain fixed points; whence it is said a thing has or has not changed place, when its distance is or is not altered with respect to those bodies.

PLACE, in optics, or OPTICAL PLACE, is the point to which the eye refers an object.

PLACE (Optic), of a star, is a point in the surface of the mundane sphere in which a spectator sees the centre of the star, &c.—This is divided into true and apparent.

True, or real optic place, is that point of the surface of the sphere, where a spectator at the centre of the earth would see the star, &c.

Apparent, or visible optic place, is that point of the surface of the sphere, where a spectator at the surface of the earth sees the star, &c.

The distance between these two optic places makes what is called the parallax.

PLACE of the sun, or moon, or star, or planet, in astronomy, simply denotes the sign and degree of the zodiac which the luminary is in; and is usually expressed either by its latitude and longitude, or by its right ascension and declination.

PLACE, in geometry, usually called *locus*, is a line used in the solution of problems, being that in which the determination of every case of the problem lies. See LOCUS, PLANE, SIMPLE, SOLID, &c.

PLACE, in war and fortification, a general name for all kinds of fortresses, where a party may defend themselves.

PLACE of ARMS, a strong part where the arms, &c. are deposited, and where usually the soldiers assemble and are drawn up.

PLACE, in ichthyology. See PLEURO-NECTES.

PLACENTA, in anatomy, (from *πλάσις*, a cake, so called from its resemblance to a cake.) The placenta is a circular, flat, vascular, and apparently fleshy substance, different in its diameter in different subjects, but usually extending about six inches, or upwards, over about one-fourth part of the outside of the ovum in pregnant women. It is more than one inch in thickness in the middle, and becomes gradually thinner towards the circumference from which

the membranes are continued. The placenta is the principal medium by which the communication between the parent and child is preserved; but though all have allowed the importance of the office which it performs, there has been a variety of opinions on the nature of that office, and of the manner in which it is executed.

That surface of the placenta which is attached to the uterus by the intervention of the connecting membrane is lobulated and convex; but the other, which is covered with the amnion and chorion, is concave and smooth, except the little eminences made by the blood vessels. It is seldom found attached to the same part of the uterus in two successive births; and, though it most frequently adheres to the anterior part, it is occasionally fixed to any other, even to the os uteri, in which state it becomes a cause of a dangerous hæmorrhage at the time of parturition. The placenta is composed of arteries and veins, with a mixture of pulpy or cellular substance. Of these there are two orders, very curiously interwoven with each other. The first is a continuation of those from the funis, which ramify on the internal surface of the placenta, the arteries running over the veins, which is a circumstance peculiar to the placenta; and then, sinking into its substance, anastomose and divide into innumerable small branches. The second order proceeds from the uterus; and these ramify in a similar manner with those from the funis, as appears when a placenta is injected from those of the parent. The veins, in their ramifications, accompany the arteries as in other parts. There have been many different opinions with respect to the manner in which the blood circulates between the parent and child, during its continuance in the uterus. For a long time it was believed that the intercourse between them was uninterrupted, and that the blood propelled by the powers of the parent pervaded, by a continuance of the same force, the vascular system of the fetus; but repeated attempts having been made without success to inject the whole placenta, funis and fœtus, from the vessels of the parent, or any part of the uterus, from the vessels of the funis, it is now generally allowed, that the two systems of vessels in the placenta, one of which may be called maternal, the other fœtal, are distinct. It is also admitted, that the blood of the fœtus is, with regard to its formation, increase, and circulation, unconnected with and totally independent of the parent: except that the matter by which the blood of the fetus is formed must be derived from the parent. It is thought that which has probably undergone some preparatory changes in its passage through the uterus, is conducted by the uterine or maternal arteries of the placenta to some cells or small cavities, in which it is deposited; and that some part of it; or something secreted from it, is absorbed by the fœtal veins of the placenta, and by them conveyed to the fetus for its nutriment. When the blood which circulates in the fetus requires any alteration

in its qualities, or when it has gone through the course of the circulation, it is carried by the arteries of the funis to the placenta, in the cells of which it is deposited, and then absorbed by the maternal veins of the placenta, and conducted to the uterus, whence it may enter the common circulation of the parent. Thus it appears, according to the opinion of Harvey, that the placenta performs the office of a gland, conveying air, or secreting the nutritious juices from the blood brought from the parent by the arteries of the uterus, and carried to the fetus by the veins of the funis, in a manner probably not unlike to that in which milk is secreted and absorbed from the breasts. The veins in the placenta are mentioned as the absorbents, because no lymphatic vessels have yet been found in the placenta or funis; nor are there any nerves in these parts; so that the only communications hitherto discovered between the parent and child, is by the sanguineous system. The proofs of the manner in which the blood circulates between the parent and child are chiefly drawn from observations made upon the funis. When it was supposed that the child was supplied with blood in a direct stream from the parent, it was asserted that, on the division of the funis, if that part next to the placenta was not secured by a ligature, the parent would be brought into extreme danger by the hemorrhage which must necessarily follow. But this opinion, which laid the foundation of several peculiarities in the management of the funis and placenta, is proved not to be true: for, if the funis be compressed immediately after the birth of the child, and whilst the circulation in it is going on, the arteries between the part compressed and the child throb violently, but those between the compression and the placenta have no pulsation; but the vein between the part compressed and the placenta swells, and that part next to the fetus becomes flaccid. But if, under the same circumstances, the funis be divided, and that part next the child be not secured, the child would be in danger of losing its life by the hemorrhage; yet the mother would suffer no inconvenience if the other part was neglected. It is moreover proved, that a woman may die of an hemorrhage occasioned by a separation of the placenta, and the child be nevertheless born, after her death, in perfect health. But if the placenta be injured, without separation, either by the rupture of the vessels which pass upon its inner surface, or in any other way, the child being deprived of its proper blood, would perish, yet the parent might escape without injury. See also SECUNDINES.

PLACENTA, in botany. See RECEPTACULUM.

PLACENTATION, in botany, est cotyledonum dispositio sub ipsa seminis germinatione. The disposition of the cotyledons or lobes in the vegetation or germinating of the seed.—Hence vegetables are distributed into—
1. Acotyledones. 2. Monocotyledones. 3. Dicotyledones. 4. Polycotyledones.

PLACENTIA, or **PLACENZA**, a duchy of

Italy, formerly the western part of the duchy of Parma; bounded on the E. by that duchy, on the N. and W. by the Milanese, and on the S. by the territory of Genoa. It is very fertile and populous, and contains mines of iron, and salt springs, from which is made a very white salt. The principal rivers are the Trebia and Nurra. It was divided between the queen of Hungary and the king of Sardinia, by the treaty of Worms, in 1743.

PLACENTIA, or **PLACENZA**, a town of Italy, capital of a duchy of the same name, with a bishop's see, a citadel, and a celebrated university. The churches, squares, streets, and fountains, are beautiful, and it contains 30,000 inhabitants. It was ceded to the king of Sardinia in 1743; and the French took possession of it in 1796. It is seated in a well cultivated country, on the river Po, 32 miles N.W. of Parma, and 83 E. of Turin. Lon. 9. 38 E. Lat. 45. 5 N.

PLACENTIA, a town of Spain, in Estremadura, with a bishop's see, and a castle. It is seated on the Xera, in a delightful plain, almost surrounded by mountains, 80 miles S.W. of Madrid. Lon. 5. 0 W. Lat. 39. 45 N.

PLACENTIA, a town of Spain, in Guipuscoa, seated on the Deva, 25 miles S.E. of Bilbao. Lon. 2. 40 W. Lat. 43. 10 N.

PLACENTIA, a seaport of Newfoundland, on a bay on the S.E. part of the island, 40 miles W. of St. John. Lon. 53. 43 W. Lat. 47. 15 N.

PLACER. *s.* (from *place*.) One who places.

PLACID. *a.* (*placidus*, Latin.) 1. Gentle; quiet; not turbulent (*Bacon*). 2. Soft; kind; mild (*Milton*).

PLACIDLY. *ad.* Mildly; gently (*Boyle*).

PLACIT. *s.* (*placitum*, Lat.) Decree; determination (*Glanville*).

PLACKET, or **PLAQUET**. *s.* A petticoat (*Shakspeare*).

PLAGAL, in music, an epithet used in opposition to authentic, and applied to the octave when arithmetically divided. When a melody is so constructed as to lie between the two extremes of an octave, making its final on one of those extremes, the mode is said to be authentic, but if the final be on the dominant, the mode is called plagal. These distinctions have, however, long since ceased to be noticed, and are only known in the old music of the church.

PLAGIANTHUS, in botany, a genus of the class monadelphia, order dodecandria. Calyx five-cleft; petals five, two of them approximate and remote from the rest; style one; stigma clavate; berry doubtful. One species, a New Zealand shrub.

PLAGIARISM. *s.* (from *plagiar*.) Literary theft; adoption of the thoughts or works of another (*Swift*).

PLAGIARY. *s.* (from *plagium*, Latin.) 1. A thief in literature; one who steals the thoughts or writings of another (*South*). 2. The crime of literary theft (*Brown*).

P L A G I A R Y.

Among the Romans, *plagiarius* was properly a person who bought, sold, or retained a freeman for a slave; and was so called because by the Flavian law such persons were condemned *ad plagas*, to be whipped. Thomasius has an express treatise *De plagio literario*; wherein he lays down the laws and measures of the right which authors have to one another's writings.—“Dictionary-writers, at least such as meddle with arts and sciences (as is pertinently observed by Mr. Chambers), seem exempted from the common laws of *meum* and *tuum*; they do not pretend to set up on their own bottom, nor to treat you at their own cost. Their works are supposed, in great measure, compositions of other people; and what they take from others, they do it avowedly, and in the open sun.—In effect, their quality gives them a title to every thing that may be for their purpose, wherever they find it; and if they rob, they do not do it, any otherwise than as the bee does, for the public service. Their occupation is not pillaging, but collecting contributions; and if you ask them their authority, they will produce you the practice of their predecessors of all ages and nations.”

It may not be amiss to remark that in many instances there may be apparent plagiarism where there is none in reality. A remarkable instance is that which relates to Leslie's most valuable work, his *Short and Easy Method with the Deists*. This seems to be a perfectly original treatise; yet it is published in French among the works of the Abbé St. Real, who died in 1692; and therefore it has been said, that unless it was published in English prior to that period, Charles Leslie must be considered as a shameless plagiarist.

The English work was certainly not published prior to the death of Abbé St. Real; for the first edition bears date July 17th, 1697; and yet many reasons conspire to convince us, that our countryman was no plagiarist. There is indeed a striking similarity between the English and the French works; but this is no complete proof that the one was copied from the other. The article *PHILOLOGY* in the *Encyclopædia Britannica*, of which Dr. Doig is the author, was published the very same week with Dr. Vincent's dissertation on the Greek verb. It was therefore impossible that either of these learned men, who were till then strangers to each others names, could have stolen aught from the other; and yet Dr. Vincent's derivation of the Greek verb bears as striking a resemblance to Dr. Doig's as the Abbé St. Real's work does to Charles Leslie's. In the article *MIRACLE* in the same *Encyclopædia*, the credibility of the gospel miracles is established by an argument, which the author certainly borrowed from no man, and which the late principal Campbell considered as original; yet within half a year of the publication of that article, the credibility of the gospel miracles was treated in the very same manner by F. Sayers, M. D. though there is in his dissertation complete internal evidence that he had not seen the article in the *Encyclopædia*.

After these instances of apparent plagiarism, which we know to be only apparent, has any man a right to say that Charles Leslie and the Abbé St. Real might not have treated their subject in the way that they have done, without either borrowing from the other? The coincidence of arrangement and reasoning in the two works is indeed very surprising; but it is by no means so surprising as the coincidence of etymological deductions which appears in the works of the doctors Doig and Vincent. The divines reason from the acknowledged laws of human thought; the reasonings of the grammarians, with all due deference to their superior learning, we cannot help considering as sometimes fanciful.

But this is not all that we have to urge on the subject. If there be plagiarism in the case, and the identity of titles looks very like it, it is infinitely more probable that the editor of St. Real's works stole from Leslie than that Leslie stole from St. Real, unless it can be proved that the works of the abbé, and this work in particular, were published before the year 1697. At that period the English language was very little read or understood on the continent; whilst in Britain the French language was, by scholars, as generally understood as at present. Hence it is that so many Frenchmen, and indeed foreigners of different nations, thought themselves safe in pilfering science from the British philosophers; whilst there is not, that we know, one well authenticated instance of a British philosopher appropriating to himself the discoveries of a foreigner. If, then, such men as Leibnitz, John Bernoulli, and Des Cartes, trusting to the improbability of detection, condescended to pilfer the discoveries of Hooke, Newton, and Harriot, is it improbable that the editor of the works of St. Real would claim to his friend a celebrated tract, of which he knew the real author to be obnoxious to the government of his own country, and therefore not likely to have powerful friends to maintain his right?

But farther, Burnet, bishop of Sarum, was an excellent scholar, and well read, as every one knows, in the works of foreign divines. Is it conceivable, that this prelate, when smarting under the lash of Leslie, would have let slip so good an opportunity of covering with disgrace his most formidable antagonist, had he known that antagonist to be guilty of plagiarism from the writings of the Abbé St. Real? Let it be granted, however, that Burnet was a stranger to these writings and to this plagiarism; it can hardly be supposed that Le Clerc was a stranger to them likewise. Yet this author, when, for reasons best known to himself, he chose (1706) to depreciate the argument of the short method, and to traduce its author as ignorant of ancient history, and as having brought forward his four marks for no other purpose than to put the deceitful traditions of popery on the same footing with the most authentic doctrines of the gospel, does not so much as insinuate that he borrowed these marks from a popish abbé.

PLA

PLAGUE. *s.* (*plaghe*, Dutch; *πληγή*.) 1. Pestilence; a disease eminently contagious and destructive (*Bacon*). 2. State of misery (*Psalms*). 3. Any thing troublesome or vexatious (*Prior*).

To PLAGUE. *v. a.* (from the noun.) 1. To infect with pestilence. 2. To infect with disease; to oppress with calamity (*Shaks. Milt.*). 3. To trouble; to tease; to vex; to harass; to torment; to afflict (*Collier*).

PLAGUE, in medicine **PESTIS**, a genus of exanthematous or eruptive fever of the typhus kind; exceedingly contagious, and accompanied with the utmost degree of debility. The exanthemata are buboes or carbuncles which issue at an uncertain period. It appears to have various species; but these have not been sufficiently defined for a regular classification. The most valuable treatise we yet possess upon the subject is that of Dr. Patrick Russell, formerly physician to the British factory at Aleppo. In this work a very full history is given of its numerous forms, and of many of its varieties. The term plague is often used in a vague and indefinite sense to signify contagious fevers of a different description, and especially the Bussorot remittent fever; which though extremely fatal, has but little resemblance to it, and occurs at a different season of the year. For the generic arrangement, description, and mode of treatment of plague or pestis, see the article **MEDICINE**, Part III. *Nosology*, Class i. Order iii. Genus xxvii: and Part IV. *Practice*, Order iii. Section *Exanthemata*.

PLA'GUILY. *ad.* (from *plaguy*.) Vexatiously; horribly (*Dryden*).

PLA'GUY. *a.* (from *plague*.) Vexatious; troublesome (*Donne*).

PLAICE. *s.* (*plate*, Dutch.) A flat fish. See **PLEURONECTES**.

PLAID. *s.* A striped or variegated cloth; an outer loose weed worn much by the highlanders in Scotland.

PLAIN. *a.* (*planus*, Lat.) 1. Smooth; level; flat; free from protuberance or excrescences. In this sense, especially in philosophical writings, it is frequently written *plane* (*Spenser*). 2. Open; clear; flat (*Felton*). 3. Void of ornament; simple (*Dryden*). 4. Artless; not subtle; not specious; not learned; simple (*Hammond*). 5. Honestly rough; open; sincere; not soft in language (*Bacon*). 6. Mere; bare (*Shakspeare*). 7. Evident; clear; discernible; not obscure (*Denham*). 8. Not varied by much art; simple (*Sidney*).

PLAIN. *ad.* 1. Not obscurely. 2. Distinctly; articulately (*Mark*). 3. Simply; with rough sincerity (*Addison*).

PLAIN. *s.* (*plaine*, Fr.) Level ground; open field; flat expanse; often, a field of battle.

To PLAIN. *v. a.* (from the noun.) To level; to make even (*Hayward*).

To PLAIN. *v. n.* (*plaindre, je plains*, Fr.) To lament; to wail (*Sidney*).

PLAINDEA'LING. *a.* (*plain and deal*.) Honest; open; acting without art (*L'Es-trange*).

PLA

PLAINDEA'LING. *s.* Management void of art; sincerity (*Dryden*).

PLAINLY. *ad.* (from *plain*.) 1. Levelly; flatly. 2. Not subtly; not speciously. 3. Without ornament. 4. Without gloss; sincerely (*Pope*). 5. In earnest; fairly (*Clar.*). 6. Evidently; clearly; not obscurely (*Milt.*).

PLAINNESS. *s.* (from *plain*.) 1. Levelness; flatness. 2. Want of ornament; want of show (*Pope*). 3. Openness; rough sincerity (*Sidney*). 4. Artlessness; simplicity (*Dryden*).

PLAIN-SONG, in music, the name given to the old ecclesiastical chant, when in its most simple state, and without those harmonic appendages with which it has long since been enriched by cultivated science.

PLAIN SAILING. See **NAVIGATION**.

PLAIN TABLE. See **PLANE TABLE**.

PLAINT. *s.* (*plainte*, French.) 1. Lamentation; complaint; lament (*Sidney*). 2. Exprobation of injury (*Bacon*). 3. Expression of sorrow (*Wotton*).

PLAINTFUL. *a.* (*plaint and full*.) Complaining; audibly sorrowful (*Sidney*).

PLAINTIF. *s.* (*plaintif*, Fr.) He that commences a suit in law against another: opposed to the *defendant* (*Dryden*).

PLAINTIF. *a.* (*plaintif*, Fr.) Complaining: not in use (*Prior*).

PLAINTIVE. *a.* (*plaintif*, French.) Complaining; lamenting; expressive of sorrow (*Dryden*).

PLAINWORK. *s.* (*plain and work*.) Needle-work as distinguished from embroidery.

PLAISE. See **PLEURONECTES**.

PLAIT. *s.* (corrupted from *plight* or *plyght*.) A fold; a double (*Davies*).

To PLAIT. *v. a.* (from the noun.) 1. To fold; to double (*Pope*). 2. To weave; to braid (*Peter*). 3. To intangle; to involve (*Shakspeare*).

PLAITER. *s.* (from *plait*.) He that plaits.

PLAN. *s.* (*plan*, French.) 1. A scheme; a form; a model (*Addison*). 2. A plot of any building, or ichnography.

To PLAN. *v. a.* (from the noun.) To scheme; to form in design (*Pope*).

PLAN, in general, denotes the representation of something drawn on a plane: such are maps, charts, ichnographies, &c. See **MAP**, **CHART**, &c.

The term **plan**, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground; shewing the extent, division, and distribution of its area, or ground-plot, into apartments, rooms, passages, &c. A geometrical plan is that, wherein the solid and vacant parts are represented in their natural proportions. The raised plan of a building, is the same with what is otherwise called an elevation, or orthography. A perspective plan, is that exhibited by degradations, or diminutions, according to the rules of perspective.

PLANARIA, in zoology, a genus of the class vermes, order intestina. Body gelatinous,

flattish, with a double ventral pore; mouth terminal. Forty-seven species, thus subdivided.

- A. Without eyes.
- B. With a single eye.
- C. With two eyes.
- D. With three eyes.
- E. With four eyes.
- F. Eyes numerous.

These are all inhabitants of Europe, chiefly of Denmark and Norway: two or three only are met with in our own country. The following will serve as specimens.

1. *P. operculata*. Body subovate, greenish-grey, with a paler line down the back, beneath paler still; furnished with a white lid which conceals the exsertile tube. Inhabits, though rarely, the sandy shores and among fuci in the bays of Norway, resembling a coffee-berry; and moves by bending its margin, and by means of its marginal folds fixes itself to and ascends other bodies.

2. *P. subulata*. Body long, pointed on the fore-part, and truncate behind. Inhabits in great plenty among marine conservæ in Greenland, and the muddy bottoms of holes in rocks which retain water through the summer, and proceeds with a serpentine kind of motion; but if the proboscis be touched, it contracts itself suddenly into a minute tube: body white, above greyish.

3. *P. quadrangularis*. Body pale, ovate, very sharp-pointed before, and winged with small, curled, longitudinal membranes. Found in the north of Europe in ditches among duckweed; very soft, pellucid, of a changeable form, and moves like a slug, leaving a slime on the bodies it passes over. When it meets another animal it draws itself in like a snail.

PLANARY. *a.* Pertaining to a plane.

PLANCHED. *a.* (from *planch.*) Made of boards (*Shakspeare*).

PLANCHER. *s.* (*plancher*, French.) A floor of wood: not used (*Bacon*).

PLANCHING. *s.* (In carpentry.) The laying the floors in a building.

PLANCINA, a woman celebrated for her intrigues and her crimes, who married Piso, and was accused with him of having murdered Germanicus, in the reign of Tiberius. She was acquitted either by means of the empress Livia, or on account of the partiality of the emperor for her person. Subservient in every thing to the will of Livia, she, at her instigation, became guilty of the greatest crimes, to injure the character of Agrippina. After the death of Agrippina, Plancina was accused of the most atrocious villanies, and as she knew that she could not elude justice, she put herself to death, A. D. 33.

PLANCUS MUNATIUS (L), a Roman consul, who forgot all his dignity, and became one of the most servile flatterers of Cleopatra and Antony. At the court of Alexandria, he appeared in the character of the meanest stage dancer, and, in comedy, he personated the sea deity Glaucus. This exposed him to public derision, and, when Antony had censured

him for his unbecoming behaviour, he deserted to Octavius, who received him with great marks of friendship and attention. It was he who proposed, in the Roman senate, that the title of Augustus should be conferred on Octavius. Horace has dedicated 1 od. 7 to him. He founded a town in Gaul, which he called Lugdunum.

PLANE, or **PLAIN**, in geometry, denotes a flat figure, or a surface lying evenly between its bounding lines. Euclid.

Some define a plane, a surface, from every point of whose perimeter a right line may be drawn to every other point in the same, and always coinciding with it.

As the right line is the shortest extent from one point to another, so is a plane the shortest extension between one line and another.

Planes are much used in astronomy, conic sections, spherics, &c. for imaginary surfaces, supposed to cut and pass through solid bodies.

When a plane cuts a cone parallel to one side, it makes a parabola; when it cuts the cone obliquely, an ellipse or hyperbola; and when parallel to its base, a circle. Every section of a sphere is a circle.

The sphere is wholly explained by planes, conceived to cut the celestial bodies, and to fill the areas or circumferences of the orbits. They are differently inclined to each other; and by us the inhabitants of the earth, the plane of whose orbit is the plane of the ecliptic, their inclination is estimated with regard to this plane.

PLANE OF A DIAL, is the surface on which a dial is supposed to be described.

PLANE, in mechanics. *A horizontal plane*, is a plane that is level, or parallel to the horizon.

Inclined plane, is one that makes an oblique angle with a horizontal plane.

The doctrine of the motion of bodies on inclined planes makes a very considerable article in mechanics, and has been fully explained under the articles **MECHANICAL POWERS**, and **INCLINED PLANE**.

PLANE OF GRAVITY, or **GRAVITATION**, is a plane supposed to pass through the centre of gravity of the body, and in the direction of its tendency; that is, perpendicular to the horizon.

PLANE OF REFLECTION, in catoptrics, is a plane which passes through the point of reflection; and is perpendicular to the plane of the glass, or reflecting body.

PLANE OF REFRACTION, is a plane passing through the incident and refracted ray.

PLANE OF THE PROJECTION, is the plane upon which the sphere is projected.

PLANE ANGLE, is an angle contained under two lines or surfaces. It is so called in contradiction to a solid angle, which is formed by three or more planes.

PLANE TRIANGLE, is a triangle formed by three right lines; in opposition to a spherical and a mixt triangle:

PLANE TRIGONOMETRY, is the doctrine of plane triangles, their measures, proportions, &c. See **TRIGONOMETRY**.

PLANE GLASS, or **MIRROR**, in optics, is a glass or mirror having a flat or even surface.

PLANE CHART, in navigation, is a sea-chart, having the meridians and parallels represented by parallel straight lines; and consequently having the degrees of longitude the same in every part. See **CHART**.

PLANE NUMBER, is that which may be produced by the multiplication of two numbers the one by the other. Thus, 6 is a plane number, being produced by the multiplication of the two numbers 2 and 3; also 15 is a plane number, being produced by the multiplication of the numbers 3 and 5. See **NUMBER**.

PLANE PLACE, (*locus planus*, or *locus ad planum*), is a term used by the ancient geometers, for a geometrical locus, when it was a right line or a circle, in opposition to a solid place, which was one of the conic sections.

These plane loci are distinguished by the moderns into *loci ad rectum*, and *loci ad circum*. See **LOCUS**.

PLANE PROBLEM, is such a one as cannot be resolved geometrically, but by the intersection either of a right line and a circle, or of the circumferences of two circles. Such as this problem following: viz. Given the hypotenuse, and the sum of the other two sides, of a right-angled triangle; to find the triangle. Or this: of four given lines to form a trapezium of a given area.

PLANE SAILING, in navigation, is the art of working the several cases and varieties in a ship's motion on a plane chart. See **NAVIGATION**.

PLANE, or **PLAIN TABLE**, in surveying, a very simple instrument, whereby the draught of a field is taken on the spot, without any future protraction. It is generally of an oblong rectangular figure, and supported by a fulcrum, so as to turn every way by means of a ball and socket. It has a moveable frame, which serves to hold fast a clean paper; and the sides of this frame, facing the paper, are divided into equal parts every way. It has also a box with a magnetical needle, and a large index with two sights; and, lastly, on the edge of the frame, are marked degrees and minutes. See **SURVEYING**.

PLANE, in joinery, an edged tool, or instrument for paring and shaving of wood smooth. It consists of a piece of wood, very smooth at bottom, as a stock or shaft; in the middle of which is an aperture, through which a steel-edge, or chisel, placed obliquely, passes; this being very sharp, takes off the inequalities of the wood it is slid along. Planes have various names, according to their various forms, sizes, and uses: as, 1. The fore-plane, which is a very long one, and is usually that which is first used: the edge of its iron or chisel is not ground straight, but rises with a convex arch in the middle; its use is to take off the greater

irregularities of the stuff, and to prepare it for the smoothing-plane. 2. The smoothing-plane is short and small, its chisel being finer; its use is to take off the greater irregularities left by the fore-plane, and to prepare the wood for the jointer. 3. The jointer is the longest of all; its edge is very fine, and does not stand out above an hair's breadth; it is chiefly used for shooting the edge of a board perfectly straight, for jointing tables, &c. 4. The strike-block, which is like the jointer, but shorter: its use is to shoot short joints. 5. The rabbit-plane, which is used in cutting the upper edge of a board, straight or square, down into the stuff, so that the edge of another cut after the same manner may join in with it, on the square; it is also used in striking facias on mouldings: the iron or chisel of this plane is as broad as its stock, that the angle may cut straight, and it delivers its shavings at the sides, and not at the top, like the others. 6. The plough, which is a narrow-rabbit plane, with the addition of two staves, on which are shoulders: its use is to plough a narrow square groove on the edge of a board. 7. Moulding-plane, which are of various kinds, accommodated to the various forms and profiles of the moulding; as the round-plane, the hollow-plane, the ogee, the snipe's bill, &c. which are all of several sizes from half an inch to an inch and a half.

PLANE-TREE. See **PLATANUS**.

PLANE-TREE (False). See **ACER**.

To **PLANE**. *v. a.* (*planer*, French.) 1. To level; to smooth; to free from inequalities (*Arbutnot*). 2. To smooth with a plane.

PLANET, a celestial body, revolving round the sun as a centre, and continually changing its position with respect to the fixed stars; whence the name planet, which is a Greek word signifying wanderer.

The planets are usually distinguished into primary and secondary. The primary ones, called by way of eminence planets, are those which revolve round the sun as a centre; and the secondary planets, more usually called satellites or moons, are those which revolve round a primary planet as a centre, and constantly attend it in its revolution round the sun.

The primary planets are again distinguished into superior and inferior. The superior planets are those farther from the sun than our earth: as Ceres, Pallas, Vesta, Juno, Mars, Jupiter, Saturn, and the Georgium Sidus; and the inferior planets are those nearer the sun than our earth, as Venus and Mercury. See **ASTRONOMY**.

That the planets are opaque bodies, like our earth, is inferred from the following reasons: 1. Since in Venus, Mercury, and Mars, only that part of the disk illuminated by the sun is found to shine; and again, Venus, and Mercury, when between the earth and the sun, appear like dark spots or maculæ on the sun's disk; it is evident, that Mars, Venus, and Mercury, are opaque bodies illuminated with the borrowed light of the sun. And the same

appears of Jupiter, from its being void of light in that part to which the shadow of the satellites reaches, as well as in that part turned from the sun; and that his satellites are opaque, and reflect the sun's light, is abundantly shown. Again, since Saturn, with his ring and satellites, only yields a faint light, fainter considerably than that of the fixed stars, though these be vastly more remote, and than that of the rest of the planets; it is past doubt that he too and his attendants are opaque bodies. 2. Since the sun's light is not transmitted through Mercury and Venus, when placed against him, it is plain they are dense opaque bodies; which is likewise evident of Jupiter, from his hiding the satellites in his shadow; and therefore, by analogy, the same may be concluded of Saturn. 3. From the variable spots of Venus, Mars, and Jupiter, it is evident these planets have a changeable atmosphere; which changeable atmosphere may, by a like argument, be inferred of the satellites of Jupiter; and therefore, by similitude, the same may be concluded of the other planets. 4. In like manner, from the mountains observed in Venus, the same may be supposed in the other planets. 5. Since, then, Saturn, Jupiter, and the satellites of both Mars, Venus, and Mercury, are opaque bodies shining with the sun's borrowed light, are furnished with mountains, and encompassed with a changeable atmosphere; they have, of consequence, waters, seas, &c. as well as dry land, and are bodies like the moon, and therefore like the earth. Q. E. D. And hence it seems also highly probable that the other planets have their animal inhabitants as well as our earth.

PLANETARIUM, an astronomical machine, contrived to represent the motions, orbits, &c. of the planets, as they really are in nature, or according to the Copernican system. A very remarkable machine of this sort was invented by Huygens, which is still preserved among the curiosities of the University at Leyden. In this planetarium, the five primary planets perform their revolutions about the sun, and the moon performs her revolution about the earth, in the same time that they are really performed in the heavens. Also the orbits of the moon and planets are represented with their true proportions, excentricity, position, and declination from the ecliptic or orbit of the earth. So that, by this machine, the situation of the planets, with the conjunctions, oppositions, &c. may be known, not only for the present time, but for any other time, either past or yet to come, as in a perpetual ephemeris. There was exhibited in London, viz. in the year 1791, a still much more complete planetarium of this sort, called "a planetarium, or astronomical machine, which exhibits the most remarkable phenomena, motions, and revolutions of the universe; invented, and partly executed, by the celebrated M. Hahn, member of the academy of sciences at Erfurt; but finished and completed by M. A. de Mylius." This is a most stupendous and elaborate

machine, consisting of the solar system in general, with all the orbits and planets in their due proportions and positions; as also the several particular planetary systems of such as have satellites, as of the earth, Jupiter, &c.; the whole kept in continual motion by a chronometer, or grand eight-day clock; by which all these systems are made perpetually to perform all their motions exactly as in nature, exhibiting at all times the true and real motions, positions, aspects, phenomena, &c. of all the celestial bodies, even to the very diurnal rotation of the planets, and the unequal motions in their elliptic orbits. A description was published of this most superb machine; and it was purchased and sent as one of the presents to the emperor of China, in the embassy of lord Macartney. See ORRERY.

PLANETARY. *a.* (*planetaire*, French.) 1. Pertaining to the planets (*Granville*). 2. Under the domination of any particular planet (*Dryden*). 3. Produced by the planets (*Shakespeare*). 4. Having the nature of a planet; erratic (*Blackmore*).

PLANETARY YEAR, DAY, and HOUR. See YEAR, DAY, and HOUR.

PLANETIC, in medicine, erratic, wandering. A term applied to fevers and other diseases which preserve no regular course or period.

PLANET-STRUCK, or SHREW-RUN, in farriery. This distemper in horses is a kind of catalepsy, or privation of feeling or motion. Not stirring any of their members, they remain in the same form as when first seized. It is an universal spasm, and to be treated like a convulsive disorder.

The ancient farriers, and many of the country people to this day, when they see a horse or bullock have the use of his limbs suddenly taken from him, and not being able to think what should be the cause of such an unexpected change, believe him either to be planet-struck or shrew-run, whence the name.

PLANIFOLIOUS. *a.* (*planus* and *folium*, Latin.) Flowers are so called, when made up of plain leaves.

PLANIMETRICAL. *a.* (from *planimetry*.) Pertaining to the mensuration of plane surfaces.

PLANIMETRY. *s.* (*planus*, Latin; and *μετρον*.) The mensuration of plane surfaces.

PLANIPETALOUS. *a.* (*planus*, Latin, and *πεταλον*.) Flatleaved, as when the small flowers are hollow only at the bottom, but flat upward, as in dandelion and succory.

To PLANISH. *v. a.* (from *plane*.) To polish; to smooth. A word used by manufacturers.

PLANISPHERE, signifies a projection of the sphere, and its various circles on a plane; in which sense maps, wherein are exhibited the meridians, and other circles of the sphere, are planispheres. See MAP, SPHERE, &c.

PLANISPHERE, is more particularly used for an astronomical instrument used in observing the motions of the heavenly bodies. It

consists of a projection of the celestial sphere upon a plane, representing the stars, constellations, &c. in their proper order; some being projected on the meridian, and others on the equator.

The use of the planisphere is to represent the face of the heavens for any day and hour.

PLANK. *s.* (*planche*, Fr.) A thick strong board (*Chapman*).

To **PLANK.** *v. a.* (from the noun.) To cover or lay with planks (*Dryden*).

PLANOCONICAL. *a.* (*planus* and *conus*, Lat.) Level on one side and conical on others (*Grew*).

PLANOCONVEX. *a.* (*planus* and *convexus*, Lat.) Flat on the one side and convex on the other (*Newton*).

PLANT, in botany, an organic vegetable body, consisting of roots and other parts. Whether capable either of sensation, or of spontaneous motion, is not yet fully ascertained. It attaches itself to other bodies, in such a manner as to derive nourishment from them, and to propagate itself by seeds. The constituent parts of plants are the roots, stems, branches, rind, or bark, leaves, flowers, and seeds; which greatly vary, both in figure and size, according to the nature of particular trees, shrubs, &c. Their various appearances have induced botanists to divide the vegetable kingdom into orders, classes, genera, species, and varieties; for an account of which, see **BOTANY**.

Thus plant is synonymous with vegetable; but frequently used in a more restricted sense. Plants are placed by Linnæus in the last of the seven families into which he has distributed the whole vegetable kingdom. Comprehending all that are not funguses, algæ, mosses, ferns, grasses, or palms. They are, 1. Herbaceous. 2. Shrubs. 3. Trees. Philos. Bot. p. 37. In Regn. Veg. he has sunk the word plantæ; and has divided them into lilia, herbæ, arbores.

PLANT (Burning thorny). See **EUPHORBIA**.

PLANT (Egg). See **SOLANUM**.

PLANT (Humble). See **MIMOSA**.

PLANT (Ice). See **MESENBRYANTHEMUM**.

PLANT (Sensitive). See **MIMOSA**.

PLANT (Bastard sensitive). See **ASCHYNOMENE**.

PLANT COAST, the name given to Botany Bay, by its original discoverer, as marked on a map in the British Museum, which is at least as old as the time of Henry VIII. Diemen's land is also marked on the same map.

PLANT (Louse). See **APHIS**.

To **PLANT.** *v. a.* (*planto*, Lat. *planter*, Fr.) 1. To put into the ground in order to grow; to set; to cultivate (*Deuteronomy*). 2. To procreate; to generate (*Shakspeare*). 3. To place; to fix (*Dryden*). 4. To settle; to establish: as, to plant a colony (*Milton*). 5. To fill or adorn with something planted: as, he planted the garden or the country. 6. To direct properly: as, to plant a cannon.

PLANTAGE. *s.* (*plantago*, Latin.) An herb, or herbs in general (*Shakspeare*).

PLANTAGENET, the surname of the kings of England from Henry II. to Richard III. inclusive. Antiquarians are much at a loss to account for the origin of this name; and the best derivation they can find for it is, that Fulk, the first earl of Anjou of that name, being stung with remorse for some wicked action, went in pilgrimage to Jerusalem as a work of atonement; where being soundly scourged with broom twigs, which grew plentifully on the spot, he ever after took the surname of plantagenet or broomstalk, which was retained by his noble posterity.

PLANTAGO. Plantain. In botany, a genus of the class tetandria, order monogynia. Calyx four-cleft; corol four-cleft, inferior, with a reflected border; stamens very long, capsule two-celled, opening transversely. Thirty-five species scattered over the globe; five common to our own country: most of them with a naked scape; a few furnished with a stem. The following are the indigenous plants.

1. *P. major*. Broad-leaved plantain. Leaves ovate, nearly glabrous, shorter than the petiole; scape round; spike with imbricate flowers; seeds numerous. Found wild in our meadows.

2. *P. media*. Hoary plantain, or lamb's-tongue. Leaves ovate, pubescent, longer than the petioles; scape round; spike cylindrical; seeds solitary. Common to our meadows.

3. *P. lanceolata*. Narrow-leaved plantain. Ribwort. Leaves lanceolate, tapering at both ends; spike ovate, naked; scape angular. Often cultivated in the vales of Gloucestershire.

4. *P. maritima*. Sea plantain. Leaves linear, mostly entire, woolly at the base, channelled; spike cylindrical; scape round. Found on our muddy shores.

5. *P. coronopus*. Buck's-horn plantain. Leaves linear, in many pinnate segments; scape round. Found on our dry heaths and sands; formerly cultivated as a salad, but long relinquished on account of its disagreeable taste.

PLANTAIN. See **PLANTAGO**.

PLANTAIN-TREE. See **HELICONIA**.

PLANTARIS. (from *planta*, the sole of the foot, to which it belongs.) Tibialis gracilis vulgo plantaris of Winslow. Extensor tarsi minor vulgo plantaris of Douglas. In myology, a muscle of the foot, situated on the leg, that assists the soleus, and pulls the capsular ligament of the knee from between the bones. It is sometimes, though seldom, found wanting on both sides. This long and slender muscle, which is situated under the gastrocnemius externus, arises, by a thin fleshy origin, from the upper and back part of the outer condyle of the os femoris. It adheres to the capsular ligament of the joint, and, after running obliquely downwards and outwards, for the space of three or four inches, along the second origin of the gastrocnemius internus, and under the gastrocnemius externus, terminates in a

long, thin, and slender tendon, which adheres to the inside of the tendo Achillis, and is inserted into the inside of the posterior part of the os calcis. This tendon sometimes sends off an aponeurosis that loses itself in the capsular ligament, but it does not at all contribute to form the aponeurosis that is spread over the sole of the foot, as was formerly supposed, and as its name would seem to imply. Its use is to assist the gastrocnemii in extending the foot. It likewise serves to prevent the capsular ligament of the knee from being pinched.

PLANTATION. *s.* (*plantatio*, Latin.) 1. The act or practice of planting. 2. The place planted (*King Charles*). 3. A colony (*Bacon*). 4. Introduction; establishment (*K. Charles*).

PLANTATION, in gardening, a large collection of different sorts of trees disposed for ornament or grown for the advantage of their timber; and not unfrequently uniting both purposes.

Under proper regulations there are few better means of improving estates, and certainly no means so essential towards an ornamental improvement of the country. Hence they are particularly worthy of attention wherever there are large tracts of poor barren lands that cannot be converted to purposes of grass or tillage.

The expence attending the formation of plantations, and the knowledge that many years must elapse before the trees can make any considerable progress, or afford any advantage, often prove an obstacle of no small weight; but if the plants be raised on the ground in a small nursery for the purpose, the expence will be very much diminished, since in such a situation plants enough may be raised in three or four years to stock a considerable number of acres; and even this with the collateral expence of transplanting, and the loss of time in waiting till the plants have attained some size, will be compensated by the first fall or thinning, in eight or ten years after planting; while the stocks which remain will shoot up again in many of the deciduous kinds, and afford a lopping every eight or ten years, exclusively of the due proportion of standards left at proper distances, to attain full growth for timber.

In forming plantations the first object of attention is to make choice of such trees as are best adapted to the nature of the particular soil and situation. That of the deciduous and ever-green kinds may be employed with propriety, and young plants of from two or three to five or ten feet in height always prove more successful than such as are older. Many persons indeed, from being in haste to have plantations as forward as possible, transplant tall trees, often of a height of twelve or fifteen feet or even more, especially among those of the ornamental kind; yet it will uniformly be found that those of younger growth always take root sooner, and establish themselves more firmly, so as to form by far the finest plantations at last, and of much the longest duration; for the large trees, from not properly rooting, like the smaller, will often fail

after they have appeared to thrive tolerably for a few years, and at length gradually dwindle away and perish.

Where ornament is chiefly intended the different kinds of hardy trees made choice of, for this purpose, should be varied as much as possible; and here we may be allowed to indulge a greater latitude in regard to their different heights, from low shrubs to trees of considerable loftiness.

With respect to the disposition of the kinds, the deciduous and ever-greens may be planted in separate compartments, or in mixtures; although the tree-kinds are occasionally planted by themselves; the plantations in their line of running being often varied towards the boundaries of lawns, parks, paddocks, &c.; and often disposed in avenues, groves, thickets, and clumps, differently arranged in different parts; and hence, at times, forming shrubberies, wildernesses, shady walks, and wood-walks; those of taller growth being placed backward, and those of lower in front; the whole being bordered with beautiful flowering shrubs, and showy ever-greens, especially next the principal walks and lawns; and the form of the several compartments being also varied by moderate sweeps and curves outward and inward, of different dimensions, by easy bends, or abrupt breaks and projections, so as to diversify the scene as much as possible in imitation of the plantations of nature. The proper distances in planting may be from five or ten to fifteen or twenty feet: in continued and ornamental plantation where required to be close for a dark thick shade, from ten to fifteen, and where glades or an intermixture of light is demanded, from fifteen to twenty; and in thickets where the shade sought for is impenetrably deep and massy, they are often planted not farther than five or six feet from each other. Where clumps are aimed at, the form should be occasionally varied from triangular to quadrangular, curved, or even rectilinear: and in wildernesses the quincunx may sometimes be introduced as a pleasing diversity.

In the formation of plantations for woods or forests, for the purpose of reaping advantage of the future timber, the best kinds, both of deciduous and ever-greens, are perhaps the oak, elm, ash, beech, chesnut, horn-beam, birch, alder, maple, sycamore, plane, poplar, lime, walnut, wild-cherry, mountain-ash, larch, willow, hazel, all which are deciduous; among the ever-greens, pine, fir, cedar of Lebanon, holly, bay, laurel, yew, ever-green oak, and box-tree.

These are sometimes raised from seeds in the spots in which they are designed to continue, but more generally in nurseries. The first is accompanied with less trouble in the rearing, but for many years afterwards demands great care and attention. The last gives us the trouble and expence of transplantation, but when this is completed the whole of the trouble and expence is at an end.

The preparation of the ground for the final

reception of the seeds or plants is mostly performed by deep ploughing and harrowing where the plough can be made use of; but where this or other tillage is impracticable only young plants from the nursery can be used, holes being dug at proper distances for the reception of each. The most proper season for performing this sort of planting, whether by seeds or plants, is dry mild weather in the autumn or winter, as from October to February, and still later if the soil be moist; when large tracts are to be planted both the seed and plant methods must be pursued all the winter at every favourable opportunity.

The grounds should be well fenced in all round with a deep ditch to guard against the encroachment of cattle or other animals: after which, the weeds should be occasionally destroyed by common hoeing, or where it can be accomplished by horse hoeing. After the third year this trouble however may be spared, and no other labour be requisite till the trees are ready for the first fall or thinning for the purpose of poles or faggots.

PLANTED. *participle.* (from *plant*.) This word seems in *Shakspeare* to signify settled; well grounded.

PLANTER. *s.* (*planteur*, French.) 1. One who sows, sets, or cultivates; cultivator (*Dryden*). 2. One who cultivates ground in the West Indian colonies (*Locke*). 3. One who disseminates or introduces (*Addison*).

PLANTERSHIP, in a general sense, the business of a planter.

PLANTERSHIP, in the West Indies, denotes the management of a sugar plantation, including not only the cultivation of the cane, but the various processes for the extraction of the sugar, together with the making of sugar-spirits. See *RUM*, *SACCHARUM*, and *SUGAR*.

PLANTING, the operation of inserting plants, seeds, and roots into the earth for the purpose of vegetation and future growth. Hence this operation is differently performed according to the nature of the material to be planted. The chief methods are as follows—hole-planting; trench-planting; slit or crevice-planting; holing-in planting; drill-planting; bedding-in planting; furrow-planting; dibble-planting; trowel-planting; planting with balls of earth round the roots; planting in pots.

Of these, however, the first is the chief and most important method, and that to which the term is often applied without any explanatory epithet or distinction. It consists in setting a tree or plant, taken from its proper place, in a new hole or pit; throwing fresh earth over its root, and filling up the hole to the level of the surface of the ground.

The first thing in this kind of planting is to prepare the ground before the trees or plants are taken out of the earth, that they may remain out of the ground as short a time as possible; and the next is, to take up the trees or plants, in order to their being transplanted. In taking up the trees, carefully dig away the earth round the roots, so as to come at their several parts to cut them off; for, if they are

torn out of the ground without care, the roots will be broken and bruised, to the great injury of the trees. When you have taken them up, the next thing is to prepare them for planting by pruning the roots and heads. And first, as to the roots; all the small fibres are to be cut off, as near to the place from whence they are produced as may be, except they are to be replanted immediately after they are taken up. Then prune off all the bruised or broken roots, all such as are irregular and cross each other, and all downright roots, especially in fruit-trees: shorten the larger roots in proportion to the age, the strength, and nature of the tree; observing that the walnut, mulberry, and some other tender-rooted kinds should not be pruned so close as the more hardy sorts of fruit and forest trees: in young fruit-trees, such as pears, apples, plums, peaches, &c. that are one year old from the time of their budding or grafting, the roots may be left only about eight or nine inches long; but in older trees, they must be left of a much greater length: but this is only to be understood of the larger roots; for the small ones must be chiefly cut quite out, or pruned very short. The next thing is the pruning of their heads, which must be differently performed in different trees; and the design of the trees must also be considered. Thus, if they are designed for walls or espaliers, it is best to plant them with the greatest part of their heads, which should remain on till they begin to shoot in the spring, when they must be cut down to five or six eyes, at the same time taking care not to disturb the roots. But if the trees are designed for standards, you should prune off all the small branches close to the place where they are produced, as also the irregular ones which cross each other; and, after having displaced these branches, you should also cut off all such parts of branches as have by any accident been broken or wounded; but by no means cut off the main leading shoots, which are necessary to attract the sap from the root, and thereby promote the growth of the tree. Having thus prepared the trees for planting, you must now proceed to place them in the earth: but first, if the trees have been long out of the ground, so that the fibres of the roots are dried, place them eight or ten hours in water before they are planted, with their heads erect, and the roots only immersed therein; which will swell the dried vessels of the roots, and prepare them to imbibe nourishment from the earth. In planting them, great regard should be had to the nature of the soil: for, if that be cold and moist, the trees should be planted very shallow; and if it be a hard rock or gravel, it will be better to raise a hill of earth where each tree is to be planted, than to dig into the rock or gravel, and fill it up with earth, as is too often practised, by which means the trees are planted as it were in a tub, and have but little room to extend their roots. The next thing to be observed is, to place the trees in the hole in such a manner that the roots may be about the same depth in the ground as before they were taken up; then break the

PLANTING.

earth fine with a spade, and scatter it into the hole, so that it may fall in between every root, that there may be no hollowness in the earth : then having filled up the hole, gently tread down the earth with your feet, but do not make it too hard ; which is a great fault, especially if the ground be strong or wet. Having thus planted the trees, they should be fastened to stakes driven into the ground to prevent their being displaced by the wind, and some mulch laid upon the surface of the ground about their roots : as to such as are planted against walls, their roots should be placed about five or six inches from the wall, to which their heads should be nailed to prevent their being blown up by the wind. The seasons for planting are various, according to the different sorts of trees, or the soil in which they are planted. For the trees whose leaves fall off in winter, the best time is the beginning of October, provided the soil be dry ; but if it be a very wet soil, it is better to defer it till the latter end of February, or the beginning of March ; and for many kinds of evergreens, the beginning of April is by far the best season ; though they may be safely removed at midsummer, provided they are not to be carried very far ; but we should always make choice of a cloudy wet season.

In the second volume of the papers, &c. of the Bath Society there is a letter on planting waste grounds. The gentleman who writes it informs us, that in the county of Norfolk, where he resides, there were about 60 or 70 years ago vast tracts of uncultivated ground, which were then thought totally barren. "The western parts of it (says he) abounded with sands of so light a texture, that they were carried about by every wind ; and in many places the sands were so loose that no grass could grow upon them. Art and industry, however, have now so altered the face of this once Arabian desert, that it wears a very different appearance. Most of these tracts are either planted, or rendered very good corn-land and sheep-walks.

"About 30 years since, the sides of many of our little sand-hills were sown with the seeds of French furze ; and when a wet season followed, they succeeded very well, and grew so fast, that once in three or four years they were cut for fuel, and sold at a good price at Thetford, Brandon, Harling, Swaffham, and places adjacent. This excited some public-spirited gentlemen, among whom was the late Mr. Buxton of Shadwell-Lodge, near Thetford, to attempt the planting of Scotch and spruce firs, and other hardy forest trees. At first they found some difficulty from the extreme looseness of the sand. But as there is in all this part of the country fine white and yellow marl, at about three feet depth below the sand, they very judiciously thought that incorporating it with the sand in the holes where their young trees were planted would insure success ; nor were they disappointed. The method succeeded beyond expectation ; the plantations throve exceedingly, and the roots

soon reached below the sand, after which they were out of danger. This excited them to further attempts.

"On the spots where they intended to raise new plantations from seeds and acorns, they laid on a thick coat of marl and clay, which, after being rough spread, and lying a winter in that state, was made fine, and ploughed in just before planting. By these means the soil became fixed, and in a little time covered with grass and herbage ; so that there are now vast plantations of firs, oak, and forest-trees, in the most healthy and vigorous state, where within my memory ten acres of land would not maintain a single sheep three months.

"But the benefit of plantations, whether of shrubs, copse, or trees, is not confined to the immediate advantage, or even the future value of the wood. By annually shedding a great number of leaves, which the winds disperse, and the rains wash into the soil, it is considerably improved ; and whenever such copses have been stubbed up, the ground (however unfruitful before planting) has thereby been so enriched as to bear excellent crops for many years, without the additional help of manure. How much land-owners are interested in planting waste or barren spots I need not mention ; and nothing but a degree of indolence or ignorance unpardonable in this enlightened age could induce them to neglect it.

"Nature has furnished us with plants, trees, and shrubs, adapted to almost every soil and situation ; and as the laws of vegetation are now much better understood than formerly, it is a reproach to those whose practice does not keep pace with their knowledge in making the best use of her bounty. Let no man repine, and say the land is barren ; for those spots which appear to be so, owe that appearance to human negligence. Industry and art might soon render an eighth part of this kingdom nearly as valuable as the rest, which now remains in a state unprofitable to the owners, and disgraceful to the community."

PLANTING (Reverse), a method of planting, in which the natural position of the plant or shoot is inverted ; the branches being set into the earth, and the root reared into the air. Dr. Agricola mentions this monstrous method of planting, which he found to succeed very well in most or all sorts of fruit-trees, timber-trees, &c. Bradley affirms, that he has seen a lime-tree in Holland growing with its first roots in the air, which had shot out branches in great plenty, at the same time that its first branches produced roots and fed the tree. Mr. Fairchild of Hoxton has practised the same with success, and gives the following directions for performing it : make choice of a young tree of one shoot, of alder, elm, willow, or any other tree that easily takes root by laying ; bend the shoot gently down into the earth, and so let it remain until it has taken root. Then dig about the first root, and raise it gently out of the ground, till the stem be nearly upright, and stake it up. Then prune the roots, now erected in the air, from the

bruises and wounds they received in being dug up; and anoint the pruned parts with a composition of two ounces of turpentine, four ounces of tallow, and four ounces of bees wax, melted together, and applied pretty warm. Afterwards prune off all the buds or shoots that are upon the stem, and dress the wounds with the same composition, to prevent any collateral shootings, that might spoil the beauty of the stem.

PLANUM OS. (*planus*, soft, smooth; applied to a bone whose surface is smooth or flat.) The papyraceous or orbital portion of the ethmoid bone was formerly so called.

PLASHING, a term used by farmers to express an operation performed at certain times upon their quickset-hedges, in order to assist their growth and continuance. This operation is performed sometimes in October, but more usually in February; and this is by much the better season for it. Suppose a hedge to be of twenty or thirty years growth, and full of old stubs as well as young shoots, this is the kind of hedge that requires plashing most of all. The old stubs must be cut off within two or three inches of the ground, and the best and longest of the middle sized shoots must be left to lay down. Some of the strongest of these must also be left to answer the purpose of stakes. These are to be cut off to the height at which the hedge is intended to be left; and they are to stand at ten feet distance one from another: when there are not proper shoots for these at the due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all those shoots which are intended to be used either as stakes, or the other work of the plashing: the ditch is to be cleaned out with the spade: the ditch must be now dug as at first, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch; all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it that this be done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone again, whereas what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge. In the plashing the quick, two extremes are to be avoided; these are, laying it too low, and laying it too thick: the former makes the sap run all into the shoots, and leaves the plashes without sufficient nourishment; which, with the thickness of the hedge, finally kills them. The other extreme of laying them too high, is equally to be avoided; for this carries up all the nourishment into the plashes, and so makes the shoots small and weak at the bottom, and consequently the hedge thin.

VOL. IX.

This is a common error in the north of England. The best hedges made any where in England, are those of Hertfordshire; and they are plashed in a middle way between the two extremes, and the cattle are by that prevented both from cropping the young shoots, and from going through; and a new and vigorous hedge soon forms itself. A new hedge raised from sets in the common way generally requires plashing about eight or nine years after.

PLASH. *s.* (*plasche*, Dutch.) 1. A small lake of water; a puddle (*Bacon*). 2. (from the verb.) Branch partly cut off and bound to other branches (*Mortimer*).

To PLASH. *v. a.* (*plesset*, Fr.) To interweave branches (*Evelyn*).

PLASHY. *a.* (from *plash*.) Watery; filled with puddles (*Bellerton*).

PLASM. *s.* (*πλασμα*) A mould; a matrix in which any thing is cast or formed (*Woodward*).

PLASMA, in mineralogy, a mineral of the nature of chalcedony, and by Gmelin arranged as one of its species. It is of a green colour of various shades, mixed with brown, and the whole arranged in dots, clouds, and bands. It occurs in mass, and in angular and rounded fragments inclosed in talc or steatite. It has a feeble, greasy lustre, both internally and externally. Its fracture is conchoidal passing to fine splintery. Its fragments are indeterminate and sharp-edged. It is translucent, and in thin pieces semi-transparent: its hardness is nearly equal to that of chalcedony: it is brittle, and easily fragile.

Its proper geological situation has not as yet been ascertained; neither has it been submitted to chemical analysis. It is not uncommon in Italy and the Levant: it occurs near Bojanovik, in Moravia, imbedded in serpentine, and near Toeltsva, in Upper Hungary, in rounded pieces with hornstone. Sometimes it combines with heliotrope and chalcedony, forming agate.

PLASSEY (Plains of), in Bengal, about 30 miles from Moorsshedabad, and 70 from Calcutta. This spot is memorable for a great victory obtained by colonel Clive, in 1757, over the nabob Surajah Dowlah; by which was laid the foundation of the present extensive British empire in Hindustan.

PLASTER. *s.* (*plastre*, Fr. from *πλάζω*.) 1. Substance made of water and some absorbent matter, such as chalk or lime well pulverized, with which walls are overlaid, or figures cast (*Pope*). 2. (*emplastrum*, Latin; in English, formerly *emplaster*.) A glutinous or adhesive salve (*Shakspeare*).

To PLASTER. *v. a.* (*plastrer*, Fr. from the noun.) 1. To overlay as with plaster (*Bacon*). 2. To cover with a medicated plaster.

PLASTER OF PARIS, in mineralogy. See GYPSUM.

PLASTERER. *s.* (*plastrier*, Fr.) 1. One whose trade is to overlay walls with plaster (*Shakspeare*). 2. One who forms figures in plaster (*Wotton*).

PLASTIC, *πλαστικός*, from *πλάσσειν*, of *πλάττω*,
F F

PLASTIC NATURE.

or *πλαστικός*, *fingo*, I fashion, form, &c. imports as much as *formative*, or a thing endued with a faculty of forming or fashioning a mass of matter after the likeness of a living being.

PLASTIC NATURE, a certain power by which, as an instrument, many philosophers, both ancient and modern, have supposed the great motions in the corporeal world, and the various processes of generation and corruption, to be perpetually carried on.

Among the philosophers of Greece, such a power was almost universally admitted. It seems, indeed, to have been rejected only by the followers of Democritus and Epicurus, who talk as if they had thought gravity essential to matter, and the fortuitous motion of atoms, which they held to have been from eternity, the source not only of all the regular motions in the universe, but also of the organization of all corporeal systems, and even of sensation and intellection, in brutes and in men. It is needless to say, that those men, whatever they might profess, were in reality atheists; and Democritus, it is universally known, avowed his atheism.

The greater part of the philosophers who held the existence of a plastic nature, considered it not as an agent in the strict sense of the word, but merely as an instrument in the hand of the Deity; though even among them there were some who held no superior power, and were of course as gross atheists as Democritus himself. Such, was Strato of Lampsacus. This man was originally of the peripatetic school, over which he presided many years, with no small degree of reputation for learning and eloquence. He was the first and chief assertor of what has been termed Hylozoic atheism; a system which admits of no power superior to a certain natural or plastic life, essential, ingenerable, and incorruptible, inherent in matter, but without sense and consciousness. That such was his doctrine we learn from Cicero, who makes Velleius the Epicurean say, "*Nec audiendus Strato qui Physicus appellatur, qui omnem vim divinam in Natura sitam esse censet, quæ causas gignendi, augendi, minuendive habeat, sed careat omni sensu.*" That Strato, in admitting this plastic principle, differed widely from Democritus, is apparent from the following account of him by the same author: "*Strato Lampsacenus negat opera deorum se uti ad fabricandum mundum, quæcunque sint docet omnia esse effecta naturæ, nec ut ille, qui asperis, et levibus, et hamatis uncinatisque corporibus concreta hæc esse dicat, interjecto inani; somnia censet hæc esse Democriti, non docentis sed optantis.*"

That the rough and smooth, and hooked and crooked, atoms of Democritus were indeed dreams and dotages, is a position which no man will controvert; but surely Strato was himself as great a dreamer when he made sensation and intelligence result from a certain plastic or spermatie life in matter, which is itself devoid of sense and consciousness. It is, indeed, inconceivable, to use the emphatic

language of Cudworth, "how any one in his senses should admit such a monstrous paradox as this, that every atom of dust has in itself as much wisdom as the greatest politician and most profound philosopher, and yet is neither conscious nor intelligent!" It is to be observed of Strato likewise, that though he attributed a certain kind of life to matter, he by no means allowed of one common life as ruling over the whole material universe. He supposed the several parts of matter to have so many several plastic lives of their own, and seems to have attributed something to chance in the production and preservation of the mundane system.

In denying the existence of a God, perpetually directing his plastic principle, and in supposing as many of these principles as there are atoms of matter, Strato deviated far from the doctrine of Aristotle. The great founder of the peripatetic school, as well as his apostate disciple, taught that mundane things are not effected by fortuitous mechanism, but by such a nature as acts regularly and artificially for ends; yet he never considers this nature as the highest principle, or supreme Numen, but as subordinate to a perfect mind or intellect; and he expressly affirms, that "mind, together with nature, formed or fashioned this universe." He evidently considers mind as the principal and intelligent agent, and nature as the subservient and executive instrument. Indeed, we are strongly inclined to adopt the opinion of the learned Mosheim, who thinks that by nature Aristotle meant nothing more than that *θερμότης φυσική*, or animal heat, to which he attributes immortality, and of which he expressly says that all things are full. Be this as it may, he always joins God and nature together, and affirms that they do nothing in vain. The same doctrine was taught before him by Plato, who affirms that "nature, together with reason, and according to it, orders all things." It must not, however, be concealed, that Plato seems to have attributed intelligence to the principle by which he supposed the world to be animated; for Chalcidius, commenting on the *Timæus*, thus expresses himself: "*Hæc est illa rationabilis anima mundi, quæ gemina juxta meliorem naturam veneratione tutelam præbet inferioribus, divinis dispositionibus obsequens, providentiam nativis impertiens, æternorum similitudine propter cognationem beata.*" Apuleius, too, tells us, "*Illam cœlestem animam, fontem animarum omnium, optimam virtutem esse genericam, subserviri etiam Fabricatori Deo, et præsto esse ad omnia inventa ejus.*" Plato pronouncieth.

This doctrine of Plato has been adopted by many moderns of great eminence both for genius and for learning. The celebrated Berkeley, bishop of Cloyne, after giving the view of Plato's *anima mundi*, which the reader will find in our article *MOTION*, thus recommends the study of his philosophy: "If that philosopher himself was not read only, but studied also with care, and made his own interpreter, I believe the prejudice that now lies against him would soon wear off, or be even

Converted into high esteem, for those exalted notions, and fine hints, that sparkle and shine throughout his writings : which seem to contain not only the most valuable learning of Athens and Greece, but also a treasure of the most remote traditions and early science of the east." Cudworth, and the learned author of *Ancient Metaphysics*, are likewise strenuous advocates for the Aristotelian doctrine of a plastic nature diffused through the material world.

PLASTIC ART, the art of representing all sorts of figures by the means of moulds.

PLASTRON, *s.* (Fr.) A piece of leather stuffed, which fencers use, when they teach their scholars, in order to receive the pushes made at them (*Dryden*).

To **PLAT**, *v. a.* (from *plait*.) To weave; to make by texture (*Addison*).

PLAT, *s.* (more properly *plot*; *plot*, Sax.) A small piece of ground (*Milton*).

PLATA, an island of Peru, on the coast of Quito, surrounded by inaccessible rocks, and about five miles long and four broad.

PLATA, a rich and populous town of Peru, capital of the audience of Los Charcos, with an archbishop's see. It is seated on the Chimao, 500 miles S.E. of Cusco. Lon. 63. 40 W. Lat. 19. 16 S.

PLATA, or **RIO-DE-LA-PLATA**, a large river of S. America, formed by the union of the three great rivers Paraguay, Uruguay, and Parana. It was discovered, in 1517, by Juan Diaz de Solis, a Spanish navigator, who was slain by the natives, in endeavouring to make a descent in the country. It crosses Paraguay, and enters the Atlantic Ocean, in lat. 35° S. It is 150 miles broad at its mouth; at Mont Video, a fort, above 100 miles up the river, the land is not to be discerned on either shore, when a vessel is in the middle of the channel; and at Buenos Ayres, 200 miles higher, the opposite shore is not to be discerned from that town.

PLATA (Rio-de-la), a province of Paraguay, on the S.W. of a river of the same name. It is subject to Spain, and at Buenos Ayres, the capital, a new vice-royalty was established in 1776. See **PERU**.

PLATÆA, an island on the coast of Africa, in the Mediterranean. It belonged to the Cyreneans.

PLATÆÆ, (*arum*), a town of Bœotia, on the confines of Megaris and Attica, celebrated for a battle fought there between Mardonius, the commander of Xerxes, king of Persia, and Pausanias the Lacedæmonian, and the Athenians. The Persian army consisted of 300,000 men, 3000 of which scarce escaped with their lives by flight. The Grecian army, which was greatly inferior, lost but few men, and among these 91 Spartans, 52 Athenians, and 16 Tegeans, were the only soldiers found in the number of the slain. This battle was fought on the 22d of September, the same day as the battle of Mycale, 479 B. C. and by it Greece was totally delivered from the alarms of the Persian invasions. **Platæa** was taken

by the Thebans, after a famous siege, in the beginning of the Peloponnesian war, and destroyed by the Spartans, B. C. 427. Alexander afterwards rebuilt it.

PLATALEA. Spoonbill. In zoology, a genus of the class aves, order grallæ. Bill long, thin; the tip dilated, orbicular, flat; nostrils small, at the base of the bill; tongue short, pointed; feet four-toed, semipalmate. Three species.

1. *P. leucorodia*. White spoonbill. Of this species there are three varieties.

a. Body white; chin black; hind-head sub-crested.

6. Wings varied with black and white; legs yellowish.

γ. Body all white; legs flesh-colour. The bill black, brown, or spotted; tongue heart-shaped; irids grey; lores, orbits, and naked, dilatable chin, black; quill-feathers sometimes tipped with black; legs black. Inhabits Europe and Asia; two feet eight inches long; feeds on fishes, frogs, snakes, and grass; builds in high trees; lays from three to four white eggs, powdered with reddish spots; flesh resembles that of a goose, especially when young.

2. *P. ajaja*. Roseat spoonbill. Body rosy; tail-coverts scarlet. Another variety blood-red; neck white; collar black; tail-feathers scarlet. Inhabits South America; two feet three inches long.

3. *P. pygmæa*. Dwarf spoonbill. Body above brown, beneath white; bill black, longer than the head, nearly rhomboid at the tip; the angles and tip of the upper mandible white; shafts of the quill-feathers white; tail short, rounded; feet cleft.

This family of birds has obtained its name from the broad, flat, and thin structure of the bill, which widens, towards the end, into a circular form, resembling a spoon. This instrument, so singular in structure, is equally so in regard to the substance of which it is composed; for it is not hard like the beak of other birds, but soft and flexible like leather. It is seven inches in length, and near two in breadth, towards the point. All round the upper mandible runs a rim, which covers the lower one. In the European species both mandibles are black, and sometimes grey; but the beak of the American spoonbill is of a red colour, resembling its feathers. These birds are nearly of the size of an heron. Their neck and legs, however, are much shorter, which gives them a smaller appearance: for, while the heron is four feet high, the spoonbills are not more than three. The European species is covered with white plumage, except on the throat and upper part of the neck, which are naked. Behind the head, there are a few long straight feathers, which form a kind of hanging crest. The two American kinds are smaller: the one is of a rose colour, and the other of a deep crimson red. The rose-coloured spoonbills inhabit Guiana and Brasil; the crimson-coloured, Mexico and Jamaica. On the American continent, these birds are generally adorned

with more lively tints, and greater brilliancy of colouring, than on the continents of the Old World. Here, however, the clumsy figure of the animal, upon which these are lavished, destroys their effects; for, with so strange a beak, and so grotesque a visage, the glaring feathers of the spoonbill seem only to add splendor to deformity.

All the different species belonging to this tribe inhabit the sea-coasts; their residence in mediterranean regions, on the borders of lakes and rivers, being only temporary; and, probably, when they are travelling from one district to another. They are spread extensively along the shores in most parts of Europe and America. Some places are famed for the vast flocks of these birds, such as the marsh, in the neighbourhood of Leyden, called Sevenhuis. Thither they crowd in great numbers, and breed in company with the herons, cormorants, and other aquatic birds of the same order, which seem to have chosen this spot for their general rendezvous.

Spoonbills construct their nests of twigs upon the summit of tall trees; generally near the sea-coast. During the season of nidification, they are extremely vociferous: at other times, they only return in the evening to sleep in the forest. The brood consists of three or four young, which are fed with aquatic insects, worms, or fishes, which constitute the subsistence of the greater part of the grallæ or waders. Spoonbills are far from being so shy as most of the aquatic tribes; whether in the water or when perched, they allow the sportsman to approach within gunshot. See Nat. Hist. Pl. CLXIX.

PLATANUS. Plane-tree. In botany, a genus of the class monocæia, order polyandria. Male: calyx a globular ament; corol hardly visible; anthers growing round the filament. Female: a globular ament; corol many petalled; stigma recurved; seed rounded, mucronate, with a capillary down at the base. Two species.

1. *P. orientalis.* Oriental plane-tree. Leaves somewhat palmate, the nerves nearly glabrous underneath: stem tall, erect, covered with a smooth bark, in the younger branches dark brown inclining to a purple; branches long, numerous, crooked at their joints; flowers upon long peduncles hanging downwards, each peduncle containing five or six balls of flowers. The flowers are so small as to be scarcely distinguished without glasses; they appear in the beginning of June a little before the leaves; the seeds ripen late in autumn, and if left upon the trees will remain till spring, when the balls fall to pieces, and the bristly down which surrounds the seeds helps to transport them to a great distance with the wind. A native of Asia, and flourishes extensively in the Levant. There are three varieties of this species.

2. Spanish plane-tree. Leaves tapering to the base, flat.

3. Middle plane-tree; leaves tapering to the base, waved.

4. Maple plane-tree. Leaves transverse.

2. *P. occidentalis.* Western or occidental plane-tree. Leaves lobe-angular; the nerves downy underneath. Stem very straight, of equal girth most part of its length; bark smooth, which the plant has the singular property of exfoliating annually; branches numerous and wide on every side; flowers still smaller than those of the former species, round balls; appear at the same time as in the former.

Both species are elegant and hardy, will bear the open plantations of our own country, and have a very ornamental effect. They may be increased by seeds, layers, or cuttings; the last two modes are the most common.

PLATBAND, in gardening, a border or bed of flowers, along a wall, or the side of a parterre, frequently edged with box, &c.

PLATBAND of a door or window, is used for the lintel, where that is made square, or not much marked.

PLATE. *s.* (plate, Dutch; plaque, Fr.)

1. A piece of metal beat out into breadth (*Shakspeare*). 2. Armour of plates (*Spenser*). 3. (plata, Spanish.) Wrought silver (*King*). 4. (plat, Fr. platta, Ital.) A small shallow vessel of metal on which meat is eaten (*Dryden*).

To PLATE. *v. a.* (from the noun.) 1. To cover with plates (*Sandys*). 2. To arm with plates (*Shakspeare*). 3. To beat into laminae or plates (*Newton*).

PLATE, in heraldry, is a round flat piece of silver, without any impression, but as it were formed ready to receive it.

PLATE is also a term used by our sportsmen, to express the reward given to the best horse at our races.

PLATES, in gunnery. The prise-plates are two plates of iron on the cheeks of a gun-carriage, from the cape square to the centre, through which the prise-bolts go, and on which the handspike rests when it poises upon the breech of the piece. Breast-plates are the two plates on the face of the carriage, one on each cheek. Train-plates are the two plates on the cheeks, at the train of the carriage. Dulidge-plates are the six plates on the wheel of a gun-carriage, where the felloes are joined together, and serve to strengthen the dulidges.

PLATED SPAR. See **SCHISTUSPATHUM.**

PLATE-LONG, in farriery, a woven strap four fathoms long, as broad as three fingers, and as thick as one, formerly made use of in the manage for raising a horse's legs, and sometimes for throwing him down, in order to facilitate the operations of the farrier.

PLATEN. *s.* Among printers, the flat part of the press whereby the impression is made.

PLAT'FORM. *s.* (plat, flat, French, and form.) 1. The sketch of any thing horizontally delineated; the ichnography (*Sandys*). 2. A place laid out after any model (*Pope*). 3. A level place before a fortification (*Shakspeare*). 4. A scheme; a plan (*Woodward*).

PLATFORM, in the military art, an elevation of earth, on which cannon is placed, to fire on the enemy; such are the mounts in the middle of curtains. On the rampart there is always a platform, where the cannon are mounted. It is made by the heaping up of earth on the rampart, or by an arrangement of madriers, rising insensibly, for the cannon to roll on, either in a casemate, or on attack in the out-works.

All practitioners are agreed, that no shot can be depended on, unless the piece can be placed on a solid platform; for if the platform shakes with the first impulse of the powder, the piece must likewise shake, which will alter its direction, and render the shot uncertain.

PLATFORM, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised. This term is also used for a kind of terrace, or broad, smooth, open walk at the top of a building, from whence a fair prospect may be taken of the adjacent country. Hence an edifice is said to be covered with a platform, when it is flat at top, and has no ridge. Most of the oriental buildings are thus covered, as were all those of the ancients.

PLATFORM, or ORLOP, in a man of war, a place on the lower deck, abaft the main-mast, between it and the cockpit, and round about the main capstan, where provision is made for the wounded men in time of action.

PLATIC ASPECT, in astrology, is a ray cast from one planet to another, not exactly, but within the orbit of its own light (*Bailey*).

PLATINA (*Bartholemia Sacchi*), born in 1421, near Mantua, author of a History of the Popes. He was appointed apostolical abbreviator under Pius II. but Paul II. removed him and all the other abbreviators from their employment. Sixtus IV. made him librarian of the Vatican, in which employment he died of the plague in 1481. He wrote several other books besides his History of the Popes.

PLATINA. See **PLATINUM**.

PLATINUM. *Platina*. In mineralogy, a genus of the class metals, deriving its name from the Spanish word *plata* or silver, in consequence of its external resemblance to it, or from the river Plata, in Spanish America, near which it is found. It is characterized by a silvery colour not tarnished by the air, very hard and tenacious, sonorous, exceedingly malleable and ductile, specific gravity 23,000; not fusible in any degree of heat, but detonating with nitre; soluble only by boiling it in sixteen times its weight of nitro-muriatic acid, and giving the solution first a yellow and then a red-brown colour; its oxyd is precipitated from this solution by the addition of muriat of ammonia, in the form of an orange powder. Found near Quito in Peru, near Santa Fe in New Granada, and near the village Choco, in mines, or mixed with sand on the banks of rivers, always in the form of small, smooth, compressed grains of the colour of polished tin, it is always combined with iron or some other metallic substance, sometimes amounting to an eighth part, which may be readily separated from it by dissolving it in muriatic acid: the heaviest and most refractory of all metals, and requires a very vehem-

ment degree of heat to render it liquid. Its tenacity is such that a wire of it 0.078 of an inch in diameter is capable of supporting a weight of 27,431 pounds averdupoise without breaking. It is easily melted by a flux of powdered glass, borax, and charcoal; and is frequently magnetic, from the quantity of iron it contains. In consequence of its great malleability, ductility, tenacity, durability, and insolubility, it is a very precious metal.

The precipitate of this metal obtained by its solution in nitro-muriatic acid, and which was at first conceived to be entirely oxyd of iron, and afterwards to be plumbago, has since been found to consist of ores of four new metals which have never been found otherwise than in this precipitate, or ore of platina. These metals are

- | | |
|-------------|---------------|
| 1. Osmium. | 3. Rhodium. |
| 2. Iridium. | 4. Palladium. |

Platinum was first brought into Europe in 1749, by Mr. Charles Wood, a paymaster of Jamaica; and in the succeeding year specimens were presented by Dr. Brownrigg to the Royal Society. These came from Carthage; from which place also were dispersed, through the Spanish West Indies, various toys and trinkets consisting of this metal alloyed with some other, probably silver, as the price of the alloy was nearly equal to that of this latter metal.

Mr. Wood and Lewes began the investigation of the properties of this new substance in the very year in which it was imported: it has since employed the abilities of all the most eminent chemists of all countries; but many difficulties still remain to be overcome before the chemical history of this substance can be completed.

Crude platinum comes from America in small flat grains of a silvery lustre. In this state it is exceedingly impure, containing, either chemically mixed, or chemically united, no less than nine other metals: but it may be reduced nearly to a state of purity by the following process.—Decant the solution from the black matter which resists the action of the acid; drop into it a solution of sal-ammoniac, an orange yellow-coloured precipitate falls to the bottom; wash this precipitate, and when dry expose it to a heat slowly raised to redness in a porcelain crucible. The powder which remains is platinum nearly pure. By re-dissolving it in nitro-muriatic acid, and repeating the whole process, it may be made still purer. When these grains are wrapped up in a thin plate of platinum heated to redness, and cautiously hammered, they unite, and the whole may be formed into an ingot.

Platinum thus obtained is of a white colour like silver, but not so bright. It has no taste nor smell. Its hardness is 8; its specific gravity, after being hammered, 23,000, so that it is by far the heaviest body known. Its ductility and tenacity we have already noticed. It is one of the most infusible of all the metals, and cannot be melted, in any quantity at least, by the strongest artificial heat which can be produced. Macquer and Beaumé melted small particles of it by means of a blowpipe, and Lavoisier by exposing them on red-hot charcoal to a stream of oxygen gass. It may indeed be melted without difficulty when combined or mixed with other bodies, but then it is not in a state of purity. Pieces of platinum, when heated to whiteness, may be welded together by hammering in the same manner as hot iron.

This metal is not in the smallest degree altered by the action of air or water.

It cannot be combined with oxygen and converted into an oxyd by the strongest artificial heat of

PLATINUM.

our furnaces. Platinum, indeed, in the state in which it is brought from America may be partially oxydized by exposure to a violent heat, as numerous experiments have proved; but in that state it is not pure, but combined with a quantity of iron. It cannot be doubted, however, that if we could subject it to a sufficient heat, platinum would burn and be oxydized like other metals; for when exposed to a very violent action of electricity, or voltaism, it has been reduced in small quantities to an oxyd form.

To obtain therefore the oxyds of this metal to any extent, it is necessary to have recourse to the action of an acid. When the deep-brown solution of platinum in nitro-muriatic acid is treated with lime-water, a yellowish brown powder falls. Dissolve this powder in nitric acid; evaporate to dryness, and apply a heat sufficient to drive off the acid. The brown powder which remains is the peroxyd of platinum. It is tasteless, and insoluble in water. When heated to redness, the oxygen is driven off, and the oxyd reduced to the metallic state. One hundred and fifteen parts of oxyd by this treatment leave 100 parts of metal. Hence the oxyd is composed of

87 platinum
13 oxygen
—
100

If the heat in this experiment be very cautiously raised, the oxyd, before it is reduced, assumes a green colour. This change is occasioned by the separation of a portion of the oxygen. The green-coloured powder is, according to Chevenix, a protoxyd of platinum. From his experiments we learn that it is composed of

93 platinum
7 oxygen
—
100

The action of the simple combustibles on this metal is not more remarkable than their action on gold.

Neither hydrogen nor carbon have been hitherto combined with it.

Phosphorus unites without difficulty, and forms a phosphuret. By mixing together an ounce of platinum, an ounce of phosphoric glass, and a drachm of powdered charcoal, and applying a heat about 320 Wedgewood, Mr. Pelletier formed phosphuret weighing more than an ounce. It was partly in the form of a button, and partly in cubic crystals. It was covered above by a blackish glass, of a silver-white colour, very brittle, and hard enough to strike fire with steel. When exposed to a fire strong enough to melt it, the phosphorus was disengaged and burnt on the surface. He found also that when phosphorus was projected on red-hot platinum, the metal instantly fused and formed a sulphuret. As heat expels the phosphorus, M. Pelletier has proposed this as an easy method of purifying platinum.

Platinum cannot be made to unite to sulphur by heating them together. In this respect it resembles gold, yet there seems to be an affinity between the two substances; for when the metal is heated with a mixture of potash and sulphur it is corroded and rendered partly soluble in water, as was proved by the experiments of Lewis and Marcgraff. And when sulphuretted hydrogen gas is passed into a solution of platinum in an acid, the metal is thrown down in dark-brown flakes, apparently in combination with sulphur.

Platinum, as far as it is known, does not combine with the simple combustibles.

It combines with most of the metals, and forms alloys; one of the most useful, as it may hereafter perhaps be found, is that with iron, since it is found to preserve the iron from rusting or oxydizing in the open air, and does not destroy its malleability.

Dr. Lewis found that gold united to platinum when they were melted together in a strong heat. He employed only crude platinum: but Vauquelin, Hatchett, and Klaproth have since examined the properties of the alloy of pure platinum and gold. To form the alloy it is necessary to fuse the metals with a strong heat, otherwise the platinum is only dispersed through the gold. When gold is alloyed with this metal, its colour is remarkably injured; the alloy having the appearance of bell-metal, or rather of tarnished silver. Dr. Lewis found that when the platinum amounted only to a sixth, the alloy had nothing of the colour of gold; even one forty-second part of platinum greatly injured the colour of the gold. The alloy formed by Mr. Hatchett of nearly eleven parts of gold to one of platinum had the colour of tarnished silver. It was very ductile and elastic. The colour of gold does not become predominant till it constitutes eight-ninths of the alloy.

From these facts it follows that gold cannot be alloyed with $\frac{1}{10}$ of its weight of platinum without easily detecting the fraud by the debasement of the colour; and Vauquelin has shown that when the platinum does not exceed $\frac{1}{10}$ it may be completely separated from gold by rolling out the alloy into thin plates, and digesting it in nitric acid, the platinum is taken up by the acid while the gold remains. But if the quantity of platinum exceed $\frac{1}{10}$ it cannot be separated completely by that method.

Osmium. Iridium. Rhodium. Palladium.—We have already observed that crude platinum is exceedingly impure, containing, as imported from America, not less than nine other metals. Of these nine, the four we have now enumerated constitute so many distinct parts, and have hitherto never been found in any other state or situation than as constituents of crude platinum: on which account it appears most congruous with a scientific work to treat of them under the present article.

It has been already observed, that in dissolving crude platinum in nitro-muriatic acid, a black powder is separated, the nature of which has been disputed. Some have regarded it as oxyd of iron, and others as plumbago; while, to settle the dispute, Mr. Tennant has lately ascertained it to contain two new metals. If in treating the crude platinum a large proportion of strong acid at a boiling temperature is made use of, nearly the whole of the black powder is dissolved, and the platinum, thrown down from the solution, by muriated ammonia, instead of being yellow is of a brick red. But if a weaker acid at a much lower temperature be employed, the solution is much less coloured, and nearly three per cent of this black powder remains, which may be readily separated by filtration and washing.

This black powder is partly in scales, and partly pulverulent. It leaves black traces on paper as plumbago does, but differs remarkably from this latter in its specific gravity, which is = 10.7. It unites readily with lead, but the compound, even if containing no more than $\frac{1}{11}$ of this black matter, possesses very little fluidity when melted. Nitrous acid dissolves all the lead, leaving the other

PLATINUM.

ingredient nearly in the same state as at first. With bismuth, zinc, and tin, the effects are nearly similar; but with copper at a very high heat it contracts a more intimate union, for by digesting the compound in nitro-muriatic acid, some of the powder was taken up together with the copper, forming a very dark-coloured solution.

With silver and gold it unites easily and intimately; and is incapable of being separated from either by cupellation, or from gold even by quartation: the alloys contain considerable ductility, and the colour of that with gold is not materially different from pure gold.

If this black powder be mixed with a large proportion of caustic soda, and kept for some time at a red heat, in a silver crucible, the mass acquires a brownish-yellow colour. On the addition of water, a peculiarly pungent odour is extricated, and the alkali with part of the yellow powder is dissolved.

This alkaline solution contains the oxyds of *osmium* and *iridium*: the former of which may be obtained pure by slightly supersaturating the solution with sulphuric acid, and proceeding to distillation; the metallic oxyd being very volatile, rising with the water, and remaining in solution with this fluid in the receiver: as, however, a little sulphuric acid is liable to come over, a second very gentle distillation is required to obtain the oxyd quite pure.

In this manner we obtain the oxyd of *osmium*. But if the black powder containing the oxyds of both the metals we have thus glanced at be fused with four times its weight of caustic potash, it will give a green saline mass; from which by digestion with water a green solution will be obtained, while some green powder will remain undissolved. The alkaline solution is to be saturated with muriatic acid, by which a green precipitate will be obtained, and this, together with the green powder, is to be digested in strong muriatic acid. The deep green muriatic solution thus prepared contains the oxyds of *iridium*, iron, and *osmium*, and when heated to ebullition its colour changes to a bright red. It is now to be gently evaporated to dryness, and the residue being treated with alcohol, the muriat of iron will be dissolved, leaving behind a red powder entirely free from this metal. This red powder being calcined at a red heat in an open crucible, then first arises muriatic acid, and then a vapour which tinges the flame of the coals of a fine blue, and which doubtless is the oxyd of *osmium*: a black powder remains behind, which when mixed with borax, and exposed to a very high heat, is reduced into a half-fused granular metal of a white colour, and very brittle, which is pure *iridium*.

All that is known of the newly discovered metal called *rhodium* has been communicated to the public by Dr. Wollaston. It is thus procured. Some crude platina being digested in moderately dilute nitro-muriatic acid, a brownish-red solution is obtained; from this the platina is to be separated for the most part by muriat of ammonia, and the residual liquor is to be heated with zinc: by this treatment a black powder will be obtained, and the supernatant fluid will consist of the muriats of zinc and iron. The black powder by digestion in very dilute nitric acid will be freed from the copper and lead which it usually contains, and the residue is to be digested in dilute nitro-muriatic acid till every thing soluble is taken up. To this solution a little common salt is to be added, and the whole evaporated to dryness; after

which, by repeatedly washing with warm alcohol the soda muriats of platina and palladium will be dissolved, leaving behind a pure soda muriat of rhodium.

If the alcoholic solution be mixed with a solution of muriated ammonia, by which the greater part of the platinum contained in it will be precipitated, the supernatant liquor being then poured off and diluted, there is to be added prussiat of potash, as long as any precipitate is produced. By this means is obtained a deep orange-coloured sediment, which changes by degrees to a dirty bottle-green. This, when dried, is to be heated with a little sulphur, and fused into a button; after which it is to be strongly heated with glass of borax, till in cooling it acquires a bright metallic surface. Being now separated from the borax, and exposed to the flame of the blow-pipe, the sulphur is volatilized, and there remains behind a spongy, malleable, metallic mass, which is pure *palladium*.

Osmium differs from all other metallic bodies in the facility with which it is oxydized when heated in the open air, or when fused with potash, while at the same time it resists the action of acids. It is equally distinguished by the great volatility of its oxyd, its peculiar smell, its solubility in water, its sweet taste, and the yellow colour which it assumes with potash. The action of the simple combustibles upon *osmium* have not been tried; nor do we know much of its combination with other metals.

Iridium has the appearance of platinum, and seems to resist the action of heat at least as strongly as that metal. It resists the action of all acids, even the nitro-muriatic almost completely: much more than three hundred parts of that acid being necessary to dissolve one of *iridium*. Its affinity with oxygen is very weak, but like all the other metals it unites with that principle. The simple combustibles have little action on it. Lead easily unites with it; and gold and silver in some degree; the colour of the gold not being essentially changed by the alloy.

Rhodium does not seem to be oxydized by exposure to air, even though assisted by heat: neither is it much acted upon by acids. It unites with sulphur readily, and, like *palladium*, is rendered fusible by it; as it is also by an union with arsenic.

Palladium obtained in a metallic state is white, and when polished bears a very close resemblance to platinum. It is rather harder than wrought iron; its specific gravity varies from 11.871 to 10.972. It is nearly as malleable as platinum, and is not altered by exposure to air; requires a violent heat to fuse it, and when strongly heated assumes a blue colour. It readily unites with sulphur; but is not altered with melted charcoal: the effects of hydrogen upon it are not known. Azot does not appear to influence it: muriatic acid oxydizes it. It forms an alloy with most metals.

PLATING, is the art of covering baser metals with a thin plate of silver either for use or for ornament. It is said to have been invented by a spur-maker, not for show but for real utility. Till then the more elegant spurs in common use were made of solid silver; and from the flexibility of that metal, they were liable to be bent into inconvenient forms by the slightest accident. To remedy this defect, a workman at Birmingham contrived to make

the branches of a pair of spurs hollow, and to fill that hollow with a slender rod of steel or iron. Finding this a great improvement, and being desirous of adding cheapness to utility, he continued to make the hollow larger, and of course the iron thicker and thicker, till at last he discovered the means of coating an iron spur with silver in such a manner as to make it equally elegant with those which were made wholly of that metal. The invention was quickly applied to other purposes: and to numberless utensils which were formerly made of brass or iron are now given the strength of these metals, and the elegance of silver, for a small additional expense. The silver plate was formerly made to adhere to the baser metal by means of solder; which is of two kinds, the soft and the hard, or the tin and silver solders. The former of these consists of tin alone, the latter generally of three parts of silver and one of brass. When a buckle, for instance, is to be plated by means of the soft solder, the ring, before it is bent, is first tinned, and then the silver plate is gently hammered upon it, the hammer employed being always covered with a piece of cloth. The silver now forms, as it were, a mould to the ring, and whatever of it is not intended to be used is cut off. This mould is fastened to the ring of the buckle by two or three cramps of iron-wire; after which the buckle, with the plated side undermost, is laid upon a plate of iron sufficiently hot to melt the tin, but not the silver. The buckle is then covered with powdered resin, or anointed with turpentine; and lest there should be a deficiency of tin, a small portion of rolled tin is likewise melted on it. The buckle is now taken off with tongs, and commonly laid on a bed of sand; where the plate and the ring, while the solder is yet in a state of fusion, are more closely compressed by a smart stroke with a block of wood. The buckle is afterwards bent and finished.

The mode of plating at present is, to fasten plates of silver upon thicker plates of copper, and then rolling them together into thin plates. The copper is twelve times thicker than the silver, and one ounce of silver is rolled to a surface of three feet or more. The plates being thus made, they are then stamped by a single stroke into the size and form of buckles, buttons, spoons, &c.

PLATO, an illustrious philosopher of antiquity, was born at Athens about 129 years B. C. His father was Aristo, the son of Aristocles, from whom he refers his origin to Solon the legislator; but his mother was Perictione, who descended from Neleus, the son of Codrus. While he was an infant, his parents are said to have placed him in Hymettus, being desirous on his account to sacrifice to the gods of that mountain, viz. Pan, and the nymphs, and the pastoral Apollo. In the mean time the bees approaching as he lay, filled his mouth with honey-combs, as an omen that in future it might be truly said of him,

Words from his tongue than honey sweeter
flow'd.

When he was a young man, he first betook himself to Dionysius the grammarian, for the purpose of acquiring common literature. After him, he employed the Argive Aristo as his instructor in Gymnastic, from whom he is said to have derived the name of Plato; for prior to this he was called Aristocles, from his grandfather. But he was so called from having those two parts of the body, the breast and forehead, broad in the extreme.

For his preceptor in music, Plato had Draco, the son of Damon, and of this master he makes mention in his Republic. After this he was instructed by the tragedians, who at that time were celebrated as the preceptors of Greece. He was likewise conversant with dithyrambic writers, as is evident from his Phædrus, which plainly breathes the dithyrambic character, and is said to have been the first dialogue which Plato composed. He was much delighted too with the comic Aristophanes and Sophron, from whom he learned the imitation of persons in dialogues. Plato also composed the following epigram on Aristophanes:

The graces emulous a grove to find
Which time might ne'er impair,
Met with the soul of Aristophanes,
And found a temple there.

He is likewise said to have written tragic and dithyrambic poems, and some other poetical pieces, all which he burned as soon as he began to associate with Socrates; at the same time repeating this verse,

Vulcan draw near, 'tis Plato asks your aid.

After the death of Socrates, he had another preceptor, the Heraclitean Cratylus, upon whom he also composed a dialogue, which is inscribed Cratylus, or concerning the rectitude of names. After he had been sufficiently instructed by this master, he went into Italy, where finding Archytus restoring a Pythagoric school, he became his disciple.

When he was in Syracuse with Dionysius the tyrant, he endeavoured to change the tyranny into an aristocracy, and it was for this purpose that he visited the tyrant. His efforts, however, were unsuccessful; for Dionysius was so indignant at the freedom of his discourse, and the dignity of his manners, that he ordered him, soon after his arrival at court, to depart at sun-rise; and when he again sailed to Sicily, at the solicitations of Dion, the tyrant delivered him to a Sicilian merchant to be sold as a slave.

Plato likewise went into Egypt for the purpose of conversing with the priests of that country, and from them learned whatever pertains to sacred rites. As he also wished to converse with the magi, but was prevented by the war which at that time broke out in Persia, he went to Phœnicia, and meeting with the magi of that country, was instructed by them in magic.

On his return to Athens, he established a school in the academy, separating a part

P L A T O .

of this Gymnasium into a temple to the muses. Here Timon the misanthrope associated with Plato alone. Plato allured very many to philosophical discipline; for he avoided the Socratic irony, and did not adopt the venerable oath of the Pythagoreans, their custom of keeping their gates shut, and their *ipse dixit*, as he wished to conduct himself in a more politic manner towards all men. His fame drew disciples from all parts, when he would admit them, as well as invitations to come to reside in many of the other Grecian states; but the three that most distinguished themselves were Spusippus his nephew, who continued the academy after him, Xenocrates the Caledonian, and the celebrated Aristotle. It is said also that Theophrastus and Demosthenes were two of his disciples. He had, it seems, so great a respect for the science of geometry and the mathematics, that he had the following inscription painted in large letters over the door of his academy: LET NO ONE ENTER HERE, UNLESS HE HAS A TASTE FOR GEOMETRY AND THE MATHEMATICS!

Plato lived 81 years, and died on his birthday. He was sumptuously buried by the Athenians; and on his tomb they inscribed the following epitaph:

Pæon and Plato from Apollo sprung,
The body's saviour this, and that the soul's.

The character of this philosopher has always been high. Besides the advantages of a noble birth, he had a large and comprehensive understanding, a vast fund of wit and good taste, great evenness and sweetness of temper, all cultivated and refined by education and travel; so that it is no wonder if he was honoured by his countrymen, esteemed by strangers, and adored by his scholars. The ancients thought more highly of Plato than of all their philosophers; they always called him the divine Plato; and they seem resolved that his descent should be more than human. "There are (says Apuleius) who assert Plato to have sprung from a more sublime conception; and that his mother Perictione, who was a very beautiful woman, was impregnated by Apollo in the shape of a spectre." Plutarch, Suidas, and others, affirm this to have been the common report at Athens: and it affords some probability that his parents themselves had some faith in the story, that they took him while an infant, as we have already related, to Hymettus, to make a sacrifice to the muses. Apuleius relates, that Socrates, the night before Plato was recommended to him, dreamed that a young swan fled from Cupid's altar in the academy, and settled in his lap; thence soared to heaven, and delighted the gods with its music: and when Aristo the next day presented Plato to him, "Friend (says Socrates), this is the swan of Cupid's academy." The Greeks loved fables: they show, however, in the present case, what exceeding respect was paid to the memory of Plato. Tully perfectly adored him; tells us, that he was justly called by Panætius, the di-

vine, the most wise, the most sacred, the Homer of philosophers; entitled him to Atticus, *Deus ille noster*; thinks, that if Jupiter had spoken Greek, he would have spoken in Plato's language; and made him so implicitly his guide in wisdom and philosophy, as to declare, that he had rather err with Plato than be right with any one else. But, panegyric aside, Plato was certainly a very wonderful man, of a large and comprehensive mind, an imagination infinitely fertile, and of a most flowing and copious eloquence. Nevertheless, the strength and heat of fancy prevailing in his composition over judgment, he was too apt to soar beyond the limits of earthly things, to range in the imaginary regions of general and abstracted ideas; and on which account, though there is always a greatness and sublimity in his manner, he did not philosophize so much according to truth and nature as Aristotle, though Cicero did not scruple to give him the preference.

The writings of Plato are all in the way of dialogue, where he seems to deliver nothing from himself, but every thing as the sentiments and opinions of others, of Socrates chiefly, of Timæus, &c. He does not mention himself anywhere, except once in his *Phædo*; and another time in his *Apology* for Socrates. His style, as Aristotle observed, is betwixt prose and verse: on which account, some have not scrupled to rank him with the poets. There is a better reason for so doing than the elevation and grandeur of his style: his matter is oftentimes the offspring of imagination, instead of doctrines or truths deduced from nature. The first edition of Plato's works in Greek was put out by Aldus at Venice, in 1513; but a Latin version of him by Marsilius Ficinus had been printed there in 1491. They were reprinted together at Lyons in 1588, and at Francfort in 1602. The famous printer, Henry Stephens, in 1578, gave a most beautiful and correct edition of Plato's works at Paris, with a new Latin version by Serranus, in three volumes folio. The latest edition with which we are acquainted is the Bipont edition of 1781, in 12 vols. octavo: it is the only edition of the entire works of Plato that has been published in an octavo form: the Greek text is taken from Serranus, and the Latin version is Ficinus's.

Of the Dialogues of Plato an edition was published by Foster, Oxon, 8vo, 1745-52-65: the first of these is the most valuable and rare. Beister published the *Meno*, *Crito*, and both the *Alcibiades* of Plato, with some notes of Gedike, Gottleber, and Scheneider, Berol. 8vo. 1780, and again more completely in 1790.

PLATONIC, something that relates to Plato, his school, philosophy, opinions, or the like.

PLATONIC BODIES are the same with what we otherwise call regular bodies.

PLATONIC LOVE denotes a pure spiritual affection, subsisting between the different sexes, abstracted from all carnal appetites, and regarding no other object but the mind, and its

PLATONISM.

beauties: or it is even a sincere disinterested friendship, subsisting between persons of the same sex, abstracted from any selfish views, and regarding no other object but the person.

The term took its rise from the philosopher Plato, a strenuous advocate for each kind.

The world has a long time laughed at Plato's notions of love and friendship.

PLATONIC YEAR, or the **GREAT YEAR**, is a period of time determined by the revolution of the equinoxes, or the space wherein the stars and constellations return to their former places in respect of the equinoxes. The Platonic year, according to Tycho Brahe, is 25816, according to Ricciolus 25920, and according to Cassini 24800 years.

PLATONISM, the philosophy of Plato, which was divided into three branches, theology, physics, and mathematics. Under theology were comprehended metaphysics and ethics, or that which in modern language is called moral philosophy. Plato wrote likewise on dialectics, but with such inferiority to his pupil Aristotle, that his works in that department of science are seldom mentioned.

The ancient philosophers always began their theological systems with some disquisition on the nature of the gods, and the formation of the world; and it was a fundamental doctrine with them, that "from nothing nothing can proceed." We are not to suppose that this general axiom implied nothing more than that for every effect there must be a cause; for this is a proposition which no man will controvert who understands the terms in which it is expressed; but the ancients believed that a proper creation is impossible even to Omnipotence, and that to the production of any thing a material is not less necessary than an efficient cause. That with respect to this important question Plato agreed with his predecessors and contemporaries appears evident to us from the whole tenor of his *Timæus*. We agree with Dr. Enfield in thinking, that in this dialogue, which comprehends his whole doctrine on the subject of the formation of the universe, matter is so manifestly spoken of as eternally co-existing with God, that this part of his doctrine could not have been mistaken by so many able and learned writers, had they not been seduced by the desire of establishing a coincidence of doctrine between the writings of Plato and Moses. It is certain that neither Cicero, nor Apuleius, nor Alcinoüs, nor even the later commentator Chalcidius, understood their master in any other sense than as admitting two primary and incorruptible principles, God, and matter; to which we shall afterwards see reason to add a third, namely ideas. The passages quoted by those who maintain the contrary opinion are by no means sufficient for their purpose. Plato, it is true, in his *Timæus*, calls God the parent of the universe, and in his *Sophista* speaks of him as "forming animate and inanimate beings, which did not before exist;" but these expressions do not necessarily imply that this offspring of Deity was produced from nothing, or that no prior matter existed from which these new beings were formed. Through the whole dialogue of the *Timæus*, Plato supposes two eternal and independent causes of all things; one that by which all things are made, which is God; the other, that from which all things are made, which is matter. He

distinguishes between God, matter, and the universe, and supposes the Architect of the world to have formed it out of a mass of pre-existent matter. Matter, according to Plato, is an eternal and infinite principle. His doctrine on this head is thus explained by Cicero: "Matter, from which all things are produced and formed, is a substance without form or quality, but capable of receiving all forms, and undergoing every kind of change; in which, however, it never suffers annihilation, but merely a solution of its parts, which are in their nature infinitely divisible, and move in portions of space which are also infinitely divisible. When that principle which we call quality is moved, and acts upon matter, it undergoes an entire change, and those forms are produced, from which arises the diversified and coherent system of the universe." This doctrine Plato unfolds at large in his *Timæus*, and particularly insists upon the notion, that matter has originally no form, but is capable of receiving any. He calls it the mother and receptacle of forms, by the union of which with matter the universe becomes perceptible to the senses; and maintains, that the visible world owes its forms to the energy of the divine intellectual nature.

Our author is supported in drawing this inference by the testimony of Diogenes Laertius, who surely understood the language and dogmas of Plato better than the most accomplished modern scholar can pretend to do; yet Dr. Ogilvie has lately expressed great surprise that any one should consider matter as having been, in Plato's opinion, uncreated; and he boldly affirms, that Laertius, instead of asserting that spirit and matter were the principles of all things, ought to have said that God alone, in Plato's estimation, was their original. To prove this, he gives from the *Timæus* a quotation, in which the founder of the Academy declares that God framed heaven and earth, and the inferior deities; and that as he fashioned, so he pervades all nature. He observes, that Cicero denominates the god of Plato the maker, and the god of Aristotle only the governor, of the world. And to satisfy those who may demand a particular proof of Plato's having taught a real creation, he affirms that his writings abound with declarations on the subject, of which the meaning cannot be misapprehended. "With this purpose (says he) Plato denominates at one time the principles or substance of all things, *τὸν κατὰ θεὸν ἀμείωτον*, the productions of the efficient Deity, and at others enters more particularly into the question. Thus, he observes, that many persons are ignorant of the nature or power of mind or intellect, 'as having existed at the beginning, antecedent to all bodies.' Of this mind, he observes, that it is without exception, *πάντων ἀπορροιατός*, of all things the most ancient; and he subjoins, in order to remove all doubt of his purpose, that it is also *ἀρχὴ κινήσεως*, the cause or principle of motion."

With all possible respect for Dr. Ogilvie, of whose piety and erudition we are thoroughly convinced, we must take the liberty to say, that to us the declarations of Plato on this subject appear much less precise and explicit than they appear to him; and that the inference which he would draw from the words of Cicero seems not to flow necessarily from the sense of those words. That Plato believed God to have framed the heaven and the earth, and to have fashioned all nature, is a position which, as far as we know, has never been controverted; but between framing and fashion-

PLATONISM.

ing the chaos or *ὡς πρῶτη*, and calling the universe into existence from non-entity, there is an infinite and an obvious difference. The distinction made by Cicero between the God of Plato and the God of Aristotle is a just distinction, but it will not bear the superstructure which the learned doctor builds upon it. Aristotle maintained the eternity of the world in its present form. Plato certainly taught that the first matter was in time reduced from a chaotic state into form by the power of the Demiurgus; but we have seen nothing in his writings which explicitly declares his belief that the first matter was itself created.

The learned Cudworth, who wished, like Dr. Ogilvie, to find a coincidence of doctrine between the theology of Plato and that of the gospel, strained all his faculties to prove that his favourite philosopher taught a proper creation; but he laboured in vain. He gives a number of quotations in support of his position; of which we shall here insert only those two upon which Dr. Ogilvie seems to lay the greatest stress. Plato, says the author of the Intellectual System, calls the one God *ὁς γῆν, οὐρανόν, καὶ θεοὺς, καὶ πάντα τὰ ἐν οὐρανῷ καὶ τὰ ἐν ᾗ, καὶ ὑπο γῆς ἀπὸ αὐτοῦ ἐργασίας*—"He that makes earth, and heaven, and the gods, and doth all things both in heaven, and hell, and under the earth." And again, "he by whose efficiency the things of the world (*ὅσπερ ἐν κόσμῳ, πρότερον οὐκ ὄντα*) were afterwards made when they were not before." Both Cudworth and Ogilvie think this last sentence an explicit declaration of Plato's belief in the creative power of God; but that they are mistaken has been evinced by Mosheim with a force of argument which will admit of no reply. In that part of the Sophist from which the quotation is taken, Plato considers the *δυναμὴν ποιητικὴν*, of which he is treating, as belonging both to God and to man; and he defines it in general to be "a certain power which is the cause that things may afterwards be which were not before." Cudworth wishes to confine this definition to the divine power; and adds from himself to the text which he quotes the following words, which are not in Plato, "or from an antecedent non-existence brought forth into being! That the incomparable author intended to deceive his reader we are far from imagining: his zeal for Platonism had deceived himself. Plato's definition comprehends the *δυναμὴν ποιητικὴν*, as well of man as of God; and therefore cannot infer a creative power any where, unless the father of the academy was so very absurd as to suppose human artists the creators of those machines which they have invented and made! Mosheim thinks that Cudworth was misled by too implicit a confidence in Ficinus; and it is not impossible that Dr. Ogilvie may have been swayed by the authority, great indeed, of the author of the Intellectual System.

That intellect existed antecedent to all bodies is indeed a Platonic dogma, from which Dr. Ogilvie, after Cudworth, wishes to infer that the doctrine of the creation was taught in the academy; but Dr. Ogilvie knows, that no man knew better than Cudworth, that Plato, with every other Greek philosopher, distinguished between body and matter; and that though he held the priority of intellect to the former, it by no means follows that he believed it to have existed antecedent to the latter. That he believed mind, or rather soul (for he distinguishes between the two), to be the cause or principle of motion, cannot be denied; but we are not therefore authorised to conclude that he likewise believed it to be the cause of the existence

of matter. That he believed mind to be the most ancient of all things, taking the word *things* in the most absolute sense, cannot be true, since by Dr. Ogilvie's own acknowledgment he held the existence and eternity of ideas, not to add that he believed *το εἶ* or *ταυταῖον*—the first hypostasis in his trinity, to be superior to mind and prior to it, though not in time, yet in the order of nature. When, therefore, he calls mind the most ancient of all things, he must be supposed to mean only that it is more ancient than all bodies and inferior souls. It is no reflection on the character of Plato that he could not, by the efforts of his own reason, acquire any notion of a proper creation; since we who have the advantage of his writings, and of writings infinitely more valuable, to instruct us, find it extremely difficult, if not impossible, to conceive how any thing can begin to be. We believe the fact on the authority of revelation; but should certainly never have agitated such a question, had it not been stated to us by writers inspired with celestial wisdom.

In the Platonic cosmogony we cannot therefore doubt but that the eternity of the *ὡς πρῶτη* was taken for granted. Whether it was an eternal and necessary emanation from an eternal mind, is not perhaps quite so evident, though our own opinion is, that it was believed to be self-existent. But be this as it may, which is not worth disputing, one thing is certain, that Plato did not believe it to have a single form or quality which it did not receive either from the Demiurgus or the Psyche—the second or third person of his trinity. Except Aristotle, all the Greek philosophers, who were not materialists, held nearly the same opinions respecting the origin of the world; so that in examining their systems we shall be greatly misled if we understand the terms *incorporeal* and *immaterial* as at all synonymous. It was also a doctrine of Plato, that there is in matter a necessary but blind and refractory force; and that hence arises a propensity in matter to disorder and deformity, which is the cause of all the imperfection which appears in the works of God, and the origin of evil. On this subject Plato writes with wonderful obscurity: but, as far as we are able to trace his conceptions, he appears to have thought, that matter, from its nature, resists the will of the Supreme Artificer, so that he cannot perfectly execute his designs; and that this is the cause of the mixture of good and evil which is found in the material world.

Plato, however, was no materialist. He taught, that there is an intelligent cause, which is the origin of all spiritual being, and the former of the material world. The nature of this great being he pronounced it difficult to discover, and when discovered impossible to divulge. The existence of God he inferred from the marks of intelligence, which appear in the form and arrangement of bodies in the visible world: and from the unity of the material system he concluded, that the mind by which it was formed must be one. God, according to Plato, is the supreme intelligence, incorporeal, without beginning, end, or change, and capable of being perceived only by the mind. He certainly distinguished the Deity not only from body, and whatever has corporeal qualities, but from matter itself, from which all things are made. He also ascribed to him all those qualities which modern philosophers ascribe to immaterial substance; and conceived him to be in his nature simple, unincircumscribed in space, the author of all regulated motion, and, in fine,

PLATONISM.

possessed of intelligence in the highest perfection.

His notions of God are indeed exceedingly refined, and such as it is difficult to suppose that he could ever have acquired but from some obscure remains of primeval tradition, gleaned perhaps from the priests of Egypt, or from the philosophers of the East. In the Divine Nature he certainly believed that there are two, and probably that there are three, hypostases, whom he called *το εν* and *το εν, vous* and *ψυχη*. The first he considered as self-existent, and elevated far above all mind, and all knowledge; calling him, by way of eminence, the being or the one. The only attribute which he acknowledged in this person was goodness; and therefore he frequently styles him *το αγαθον*—“the good, or essential goodness.” The second he considered as mind, the wisdom or reason of the first, and the maker of the world; and therefore he styles him *vous*, *λογος*, and *δημιουργος*. The third he always speaks of as the soul of the world; and hence calls him *ψυχη*, or *ψυχη του κοσμου*. He taught that the second is a necessary emanation from the first, and the third from the second, or perhaps from the first and second.

Some have indeed pretended, that the Trinity, which is commonly called Platonic, was a fiction of the later Platonists, unknown to the founder of the school: but any person who shall take the trouble to study the writings of Plato will find abundant evidence that he really asserted a triad of divine hypostases, all concerned in the formation and government of the world. Thus, in his 10th book of Laws, where he undertakes to prove the existence of a Deity in opposition to atheists, he ascends no higher in the demonstration than to the *ψυχη* or mundane soul, which he held to be the immediate and proper cause of all the motion that is in the world. But in other parts of his writings he frequently asserts, as superior to the self-moving principle, an immovable *vous* or intellect, which was properly the demiurgus or framer of the world; and above this hypostasis one most simple and absolutely perfect being, who is considered in his Theology as *αυτοθεος*, the original deity, in contradiction from the others, who are only *θεοι εκ στοι*. These doctrines are to be gathered from his works at large, particularly from the *Timæus*, *Philebus*, *Sophista*, and *Epinomis*: but there is a passage in his second epistle to Dionysius, apparently written in answer to a letter which that monarch had required him to give a more explicit account than he had formerly done of the nature of God, in which the doctrine of a Trinity seems to be directly asserted. “After having said that he meant to wrap up his meaning in such obscurity, as that an adept only should fully comprehend it, he adds expressions to the following import: “The Lord of Nature is surrounded on all sides by his works: whatever is, exists by his permission: he is the fountain and source of excellence: around the second person are placed things of the second order; and around the third those of the third degree.” Of this obscure passage a very satisfactory explanation is given in Dr. Ogilvie's Theology of Plato, to which the narrow limits prescribed to such articles as this compel us to refer the reader. We shall only say, that the account which we have given of the Platonic Trinity is ably supported by the doctor.

In treating of the eternal emanation of the second and third hypostases from the first, the philosophers of the academy compare them to light and heat proceeding from the sun. Plato himself,

as quoted from Dr. Cudworth, illustrates his doctrine by the same comparison. For “*το αγαθον*, or the first hypostasis, is in the intellectual world the same (he says) to intellect and intelligibles that the sun is in the corporeal world to vision and visibles; for, as the sun is not vision itself, but the cause of vision, and as that light by which we see is not the sun, but only a thing like the sun; so neither is the Supreme or Highest Good properly knowledge, but the cause of knowledge; nor is intellect, considered as such, the best and most perfect being, but only a being having the form of perfection.” Again, “as the sun causes other things not only to become visible, but also to be generated; so the Supreme Good gives to things not only their capability of being known, but also their very essences by which they subsist; for this fountain of the Deity, this highest good, is not itself properly essence, but above essence, transcending it in respect both of dignity and of power.”

The resemblance which this trinity of Plato bears to that revealed in the gospel must be observed by every attentive reader; but the two doctrines are likewise in some respects exceedingly dissimilar. The third hypostases in the Platonic system appears in no point of view co-ordinate with the first or second. Indeed, the first is elevated far above the second, and the third sunk still further beneath it, being considered as a mere soul immersed in matter, and forming with the corporeal world, to which it is united, one compound animal. Nay, it does not appear perfectly clear, that Plato considered his *ψυχη του κοσμου* as a pure spirit, or as having subsisted from eternity as a distinct hypostasis. “This governing spirit, of whom the earth, properly so called, is the body, consisted, according to our author's philosophy, of the same and the other; that is, of the first matter, and of pure intelligence, framed to actuate the machinery of nature. The Supreme Being placed him in the middle of the earth; which, in the vivid idea of Plato, seemed itself to live, in consequence of an influence that was felt in every part of it. From this seat his power is represented as being extended on all sides to the utmost limit of the heavens; conferring life, and preserving harmony in the various and complicated parts of the universe. Upon this being God is said to have looked with peculiar complacency after having formed him as an image of himself, and to have given beauty and perfect proportion to the mansion which he was destined to occupy. According to the doctrine of *Timæus*, the Supreme Being struck out from this original mind innumerable spirits of inferior order, endowed with principles of reason; and he committed to divinities of secondary rank the task of investing these in material forms, and of dispersing them as inhabitants of the sun, moon, and other celestial bodies. He taught also, that at death the human soul is reunited to the *ψυχη του κοσμου*, as to the source from which it originally came.”

Such is the third person of the Platonic triad, as we find his nature and attributes very accurately stated by Dr. Ogilvie; and the Christian philosopher, who has no particular system to support, will not require another proof that the triad of Plato differs exceedingly from the Trinity of the Scriptures. Indeed the third hypostasis in this triad has so much the appearance of all that the ancients could mean by that which we call a creature, that the learned Cudworth, who wished, it is difficult to conceive for what reason, to find the sublim-

PLATONISM.

est mystery of the Christian faith explicitly taught in the writings of a pagan philosopher, was forced to suppose, that Plato held a double $\psi\upsilon\chi\eta$, or soul, one $\epsilon\chi\kappa\omicron\sigma\mu\omicron\upsilon\sigma\iota\varsigma$ incorporated with the material world, and the other $\sigma\upsilon\pi\epsilon\tau\epsilon\tau\omicron\sigma\mu\omicron\upsilon\sigma\iota\varsigma$ or supramundane, which is not the soul but the governor of the universe. We call this a mere hypothesis; for, though the author displays vast erudition, and adduces many quotations in which this double psyche is plainly mentioned, yet all those quotations are taken from Platonists who lived after the propagation of the gospel, and who, calling themselves eclectics, freely stole from every sect such dogmas as they could incorporate with their own system, and then attributed those dogmas to their master. In the writings of Plato himself, there is not so much as an allusion to this supramundane psyche; and it is for this reason (the $\psi\upsilon\chi\eta$ of which he treats being so very inferior to the $\delta\eta\mu\iota\omicron\upsilon\gamma\omicron\upsilon\gamma\omicron\varsigma$ and $\alpha\gamma\alpha\theta\omicron\varsigma$) that we have expressed with hesitation his belief of three hypostases of the divine nature. Yet that he did admit so many seems more than probable both from the passage illustrated by Dr. Ogilvie, and from the attempt of Plotinus, one of his followers, to demonstrate that the number can be neither greater nor less. That his doctrine on this subject should be inaccurate and erroneous can excite no wonder; whilst it must be confessed to have such a resemblance to the truth, and to be so incapable of being proved by reasoning from effects to causes, that we could not doubt of his having inherited it by tradition, even though we had not complete evidence that something very similar to it was taught long before him, not only by Pythagoras and Parmenides, but by the philosophers of the East.

We have said that the Demiurgus was the maker of the world from the first matter which had existed from eternity; but in Plato's cosmogony there is another principle, more mysterious, if possible, than any thing which we have yet mentioned. This is his intellectual system of ideas, which it is not easy to collect from his writings, whether he considered as independent existences, or only as archetypal forms, which had subsisted from eternity in the $\lambda\omicron\gamma\omicron\varsigma$ or divine intellect. On this subject he writes with such exceeding obscurity, that men of the first eminence both among the ancients and the moderns have differed about his real meaning. Some have supposed, that by ideas he meant real beings subsisting from eternity, independent of all minds, and separate from all matter; and that of these ideas he conceived some to be living and others to be without life. In this manner his doctrine is interpreted by Tertullian among the ancients, and by the celebrated Brucker among the moderns; and not by them only, but by many others equally learned, candid, and acute. Cudworth, on the other hand, with his annotator Mosheim, contends, that by his ideal world, Plato meant nothing more than that there existed from eternity in the $\lambda\omicron\gamma\omicron\varsigma$ or mind of God a notion or conception of every thing which was in time to be made. This is certainly much more probable in itself, than that a man of enlarged understanding should have supposed, that there are somewhere in extramundane space real living incorporeal beings eating and drinking, which are the ideas of all the animals which ever have been or ever will be eating and drinking in this world. Yet Mosheim candidly acknowledges, that if the controversy were to be decided by the votes of the learned, he is doubtful whether it would be given for or against him; and Cudworth, though he

pleads the cause of his master with much ingenuity, owns, that on this subject his language cannot be vindicated. This indeed is most true; for Plato contends, that his ideas are not only the objects of science, but also the proper or physical causes of all things here below; that the idea of similitude is the cause of the resemblance between two globes; and the idea of dissimilitude the cause that a globe does not resemble a pyramid: he likewise calls them *οὐσιαι*, essences or substances, and many of his followers have pronounced them to be animals.

It was a fundamental doctrine in the system of Plato, that the Deity formed the material world after a perfect model, consisting of those ideas which had eternally subsisted in his own reason: and yet, with some appearance of contradiction, he calls this model "self-existent, indivisible, and eternally generated." Nay, he talks of it as being intelligent as well as eternal, and wholly different from the transcripts, which are subjected to our inspection. There is so much mystery, confusion, and apparent absurdity, in the whole of this system, as it has come down to us, that we must suppose the friends of Plato to have been intrusted with a key to his esoteric doctrines, which has long been lost; otherwise it would be difficult to conceive how that philosopher could have had so many admirers.

With almost every ancient theist of Greece, the founder of the academy believed in an order of beings called *δαίμονες*, which were superior to the souls of men, and struck off by the Demiurgus from the soul of the world. Of these the reader will find some account elsewhere. (See *DÆMON* and *POLYTHEISM*.) We mention them at present because they make an important appearance in Plato's system of Physics, which was built upon them, and upon the doctrine which has been stated concerning God, matter, and ideas. He taught, that the visible world was formed by the Supreme Architect uniting eternal and immutable ideas to the first matter; that the universe is one animated being, including within its limits all animated natures; that, in the formation of the visible and tangible world, fire and earth were first formed, and were afterwards united by means of air and water; that from perfect parts one perfect whole was produced of a spherical figure, as most beautiful in itself, and best suited to contain all other figures; that the elementary parts of the world are of regular geometrical forms, the particles of earth being cubical, those of fire pyramidal, those of air in the form of an octahedron, and those of water in that of an icosahedron; that these are adjusted in number, measure, and power, in perfect conformity to the geometrical laws of proportion; that the soul which pervades this sphere is the cause of its revolution round its centre; and, lastly, that the world will remain for ever, but that by the action of its animating principle it accomplishes certain periods, within which every thing returns to its ancient place and state. This periodical revolution of nature is called the Platonic or great year.

The metaphysical doctrines of Plato which treat of the human soul, and the principles of his system of ethics, cannot here be detailed; but it is worthy of observation in this place, that, preparatory to the study of all philosophy, he required from his disciples a knowledge of the elements of mathematics. In his Republic, he makes Glaucous, one of the speakers, recommend them for their usefulness in human life. "Arithmetic for accounts

and distributions; geometry for incampments and mensurations; music for solemn festivals in honour of the gods; and astronomy for agriculture, for navigation, and the like. Socrates, on his part, denies not the truth of all this, but still insinuates that they were capable of answering an end more sublime. "You are pleasant (says he) in your seeming to fear the multitude, lest you should be thought to enjoin certain sciences that are useless." 'Tis indeed no contemptible matter, though a difficult one, to believe, that through these particular sciences the soul has an organ purified and enlightened, which is destroyed and blinded by studies of other kinds; an organ better worth saving than a thousand eyes, in as much as truth becomes visible through this alone.

"Concerning policy, Plato has written at large in his Republic and in his Dialogue on Laws. He was so much enamoured with his own conceptions on this subject, that it was chiefly the hope of having an opportunity to realise his plan of a republic which induced him to visit the court of Dionysius. But they who are conversant with mankind, and capable of calmly investigating the springs of human actions, will easily perceive that his projects were chimerical, and could only have originated in a mind replete with philosophical enthusiasm. Of this nothing can be a clearer proof than the design of admitting in his republic a community of women, in order to give reason an entire controul over desire. The main object of his political institutions appears to have been, the subjugation of the passions and appetites, by means of the abstract contemplation of ideas. A system of policy, raised upon such fanciful grounds, cannot merit a more distinct consideration."

PLATOON, in the military art, a small square body of forty or fifty men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is not room for whole battalions or regiments. Platoons are also used when they form the hollow square, to strengthen the angles. The grenadiers are generally posted in platoons.

PLATTER. *s.* (from *plate*.) A large dish, generally of earth (*Dryden*).

PLAT-VEIN, or **PLATE-VEIN**, in a horse, a vein running on the inside of each fore thigh, a little below the elbow, so called among common farriers. It is the basilic vein.

PLATYLOBIUM, in botany, a genus of the class diadelphia, order decandria. Calyx campanulate, five-cleft; the two upper segments very large and obtuse; legume pedicelled, compressed, winged along the back, many-seeded. All Australasian shrubs, with yellow flowers.

PLATYPUS, in zoology, a genus of the class mammalia, order bruta. Mouth shaped like the bill of a duck; feet palmate. One species only, *P. anatinus*, duck-billed platypus.—"Of all the mammalia," says Dr. Shaw, "yet known, it seems the most extraordinary in its conformation; exhibiting the perfect resemblance of the beak of a duck engrafted on the head of a quadruped. So accurate is the similitude, that at first view it naturally excites the idea of some deceptive preparation by artificial means: the very epidermis, propor-

tion, serratures, manner of opening, and other particulars of the beak of a shoveller, or other broad-billed species of duck, presenting themselves to the view: nor is it without the most minute and rigid examination that we can persuade ourselves of its being the real beak or snout of a quadruped.

"The body is depressed, and has some resemblance to that of an otter in miniature: it is covered with a very thick, soft, and beaver-like fur, and is of a moderately dark brown above, and of a subferruginous white beneath. The head is flattish, and rather small than large: the mouth or snout, as before observed, so exactly resembles that of some broad-billed species of duck that it might be mistaken for such: round the base is a flat circular membrane, somewhat deeper or wider below than above; viz. below near the fifth of an inch, and above about an eighth. The tail is flat, furry like the body, rather short, and obtuse, with an almost bifid termination: it is broader at the base, and gradually lessens to the tip, and is about three inches in length: its colour is similar to that of the body. The length of the whole animal from the tip of the beak to that of the tail is thirteen inches: of the beak an inch and half. The legs are very short, terminating in a broad web, which on the fore-feet extends to a considerable distance beyond the claws; but on the hind feet reaches no farther than the roots of the claws. On the fore-feet are five claws, strait, strong, and sharp-pointed: the two exterior ones somewhat shorter than the three middle ones. On the hind-feet are six claws, longer and more inclining to a curved form than those of the fore-feet: the exterior toe and claw are considerably shorter than the four middle ones: the interior or sixth is seated much higher up than the rest, and resembles a strong sharp spur. All the legs are hairy above: the fore-feet are naked both above and below; but the hind-feet are naked above and hairy below. The internal edges of the under mandible, (which is narrower than the upper) are serrated or channelled with numerous striæ, as in a duck's bill. The nostrils are small and round, and are situated about a quarter of an inch from the tip of the bill, and are about the eighth of an inch distant from each other. There is no appearance of teeth; the palate is removed, but seems to have resembled that of a duck; the tongue also is wanting in the specimen. The ears or auditory foramina are placed about half an inch beyond the eyes; they appear like a pair of oval holes of the eighth of an inch in diameter, there being no external ear. On the upper part of the head, on each side, a little beyond the beak, are situated two smallish oval white spots, in the lower part of each of which are imbedded the eyes, or at least the parts allotted to the animal for some kind of vision; for from the thickness of the fur and the smallness of the organs they seem to have been but obscurely calculated for distinct vision, and are probably like those of moles, and some other animals of that tribe; or perhaps even

Phoca.

Phoca, Ursine Seal.

Trichechus.

Platypus.

P. lustratus Duck-billed Platypus.

subcutaneous; the whole apparent diameter of the cavity in which they were placed not exceeding the tenth of an inch.

"When we consider the general form of this animal, and particularly its bill and webbed feet, we shall readily perceive that it must be a resident in watery situations; that it has the habits of digging or burrowing in the banks of rivers, or under ground; and that its food consists of aquatic plants and animals. This is all that can at present be reasonably guessed at: future observations, made in its native regions, will, it is hoped, afford us more ample information, and will make us fully acquainted with the natural history of an animal which differs so widely from all other quadrupeds, and which verifies in a most striking manner the observation of Buffon; viz. that whatever was possible for nature to produce, has actually been produced.

"On a subject so extraordinary as the present, a degree of scepticism is not only pardonable, but laudable; and I ought, perhaps, to acknowledge that I almost doubt the testimony of my own eyes with respect to the structure of this animal's beak; yet must confess that I can perceive no appearance of any deceptive preparation; and the edges of the rictus, the insertion, &c. when tried by the test of maceration in water, so as to render every part completely moveable, seem perfectly natural; nor can the most accurate examination of expert anatomists discover any deception in this particular.

"The platypus is a native of Australasia or New Holland, and is at present in the possession of Mr. Dobson, so much distinguished by his exquisite manner of preparing specimens of vegetable anatomy." See Nat. Hist. Pl. CLXVIII.

PLATYSMA MYOIDES. (from *μας*, broad, *μυς*, a muscle, and *ειδος*, resemblance.) In myology, musculus cutaneus of Winslow. Quadratus genæ vel Latissimus colli of Douglas. Latissimus colli of Albinus. Detrahens quadratus. A thin muscle on the side of the neck, immediately under the skin, that assists in drawing the skin of the cheek downwards; and when the mouth is shut, it draws all that part of the skin to which it is connected below the lower jaw upwards.

PLATYSTACUS, in ichthyology. See **SILURUS ASPREDO**.

PLAUDIT. PLAU'DITE. *s.* Applause (*Denham*).

PLAUSIBILITY. *s.* (*plausibilité*, French.) Speciousness; superficial appearance of right (*Swift*).

PLAUSIBLE. *a.* (*plausible*, French.) Such as gains approbation; superficially pleasing or taking; specious; popular (*Clarendon*).

PLAUSIBLENESS. *s.* (from *plausible*.) Speciousness; show of right (*Sanderson*).

PLAUSIBLY. *ad.* (from *plausible*) 1. With fair show; speciously (*Collier*). 2. With applause: not in use (*Brown*).

PLAUSIVE. *a.* (from *plaudo*, Latin.) 1.

Applauding. 2. Plausible. A word not in use (*Shakspeare*).

PLAUTIANUS (Fulvius), an African of mean birth, who was banished for his seditious behaviour in the years of his obscurity. In his banishment Plautianus formed an acquaintance with the emperor Severus, who, some years after, ascended the imperial throne. This was the beginning of his prosperity; Severus invested him with power equal to his own at Rome and in the provinces, and he wanted but the name of emperor to be his equal. He was concerned in all the rapine and destruction which was committed through the empire, and he enriched himself with the possessions of those who had been sacrificed to the emperor's cruelty or avarice. He was put to death for conspiring against the emperor and his son Caracalla, who had some time before married his daughter Plautilla. Severus banished Plautilla to the island of Lipari, with her brother Plautius, where, seven years after, she was put to death by order of Caracalla, A.D. 211.

PLAUTUS (Marcus Accius), a comic writer of ancient Rome, born in Umbria, a province of Italy. His proper name was Marcus Accius, and he is supposed to have acquired the surname of Plautus from having splay feet. His parentage appears to have been mean; so that some have thought he was the son of a slave. Aulus Gellius says that Plautus was distinguished for his poetry on the theatre, and Cato for his eloquence in the forum, at the same time; and observes elsewhere from Varro, that he was so well paid for his plays as to double his stock in trading, in which he lost all he gained by the muses. He is said to have been reduced to work at a mill for his subsistence; but Varro adds, that his wit was his best support, as he composed three of his plays during this drudgery. He died the first year of the elder Cato's censorship, about the year of Rome 569, and 184 B. C. We have twenty of his plays extant, though not all of them entire. Five of them, comedies, have been elegantly translated into English by Mr. B. Thornton, and published in 2 vols. 8vo. 1767.

The editio princeps was published in 1472, in folio: it is a very beautiful work, and was edited by Georgius Merula. The folio edition of Lambinus in 1577 is very admirable; other valuable editions are those of Taubman in 1612—22, of Gronovius in 1684, of Ernesti in 1760, and the Bipont editions of 1779 and 1788.

TO PLAY. *v. n.* (*plegan*, Saxon.) 1. To sport; to frolic; to do something not as a task, but for pleasure (*Milton*). 2. To toy; to act with levity (*Milton*). 3. To be dismissed from work (*Shakspeare*). 4. To trifle; to act wantonly and thoughtlessly (*Temple*). 5. To do something fanciful (*Shakspeare*). 6. To practise sarcastic merriment (*Pope*). 7. To mock; to practise illusion (*Shakspeare*). 8. To game; to contend at some game (*Shakspeare*). 9. To do any thing trickish or deceitful (*Addison*).

16. To touch a musical instrument (*Gran.*). 11. To operate; to act. Used of any thing in motion: as, *the cannons play* (*Cheyne*). 12. To wanton; to move irregularly: *the leaves play with the wind* (*Dryden*). 13. To personate a drama (*Shakspeare*). 14. To represent a character (*Donne*). 15. To act in any certain character (*Collier*).

To PLAY. *v. a.* 1. To put in action or motion: as, *he played his cannon*. 2. To use an instrument of music (*Gay*). 3. To act a mirthful character (*Milton*). 4. To exhibit dramatically (*Shakspeare*). 5. To act; to perform (*Sidney*).

PLAY. *s.* 1. Action not imposed; not work. 2. Amusement; sport (*Milton*). 3. A drama; a comedy or tragedy, or any thing in which characters are represented by dialogue and action (*Dryden*). 4. Game; practice of gaming; contest at a game (*Shakspeare*). 5. Practice in any contest (*Tillotson*). 6. Action; employment; office (*Dryden*). 7. Practice; action; manner of acting (*Sidney*). 8. Act of touching an instrument. 9. Irregular and wanton motion. 10. A state of agitation or ventilation (*Dryden*). 11. Room for motion (*Moxon*). 12. Liberty of acting; swing (*Ad-dison*).

PLAYBOOK. *s.* (*play and book.*) Book of dramatic compositions (*Swift*).

PLAYDAY. *s.* (*play and day.*) Day exempt from tasks or work (*Swift*).

PLAYDEBT. *s.* (*play and debt.*) Debt contracted by gaming (*Arbuthnot*).

PLAYER. *s.* (*from play.*) 1. One who plays. 2. An idler; a lazy person (*Shaks.*). 3. Actor of dramatic scenes (*Sidney*). 4. A mimic (*Dryden*). 5. One who touches a musical instrument. 6. A gamester. 7. One who acts in play in any certain manner (*Carew*).

PLAYERS ON HIGH AND LOW INSTRUMENTS. A title assumed by the French minstrels of the fourteenth century, when the laws of counterpoint were forming, and began to give exercise to bass and treble instruments in concert. A denomination which was afterwards confirmed by a charta in the year 1401, granted them by Charles VI.

PLAYFELLOW. *s.* (*play and fellow.*) Companion in amusement (*Spenser*).

PLAYFUL. *a.* (*play and full.*) Sportive; full of levity (*Addison*).

PLAYGAME. *s.* (*play and game.*) Play of children (*Locke*).

PLAYHOUSE. *s.* (*play and house.*) House where dramatic performances are represented.

PLAYPLEASURE. *s.* (*play and pleasure.*) Idle amusement (*Bacon*).

PLAYSOME. *a.* (*play and some.*) Wanton; full of levity.

PLAYSOMENESS. *s.* Wantonness; levity.

PLAYTHING. *s.* (*play and thing.*) Toy; thing to play with (*Otway*).

PLAYWRIGHT. *s.* (*play and wright.*) A maker of plays (*Pope*).

PLEA. *s.* (*plaid, old French.*) 1. The act or

form of pleading. 2. Thing offered or demanded in pleading (*Shakspeare*). 3. Allegation (*Milton*). 4. An apology; an excuse (*Milton*).

PLEA, in law, is what either party alleges for himself in court, in a cause there depending; and in a more restrained sense, it is the defendant's answer to the plaintiff's declaration. Pleas are usually divided into those of the crown and common pleas. Pleas of the crown are all suits in the king's name, or in the name of the attorney-general in behalf of the king, for offences committed against his crown and dignity, and against his peace; as treason, murder, felony, &c. See ARRAIGNMENT. Common pleas are such suits as are carried on between common persons in civil cases. These pleas are of two sorts; dilatory pleas, and pleas to the action. Dilatory pleas are such as tend merely to delay or put off the suit, by questioning the propriety of the remedy, rather than by denying the injury: pleas to the action are such as dispute the very cause of suit.

(1.) Dilatory pleas are, 1. To the jurisdiction of the court; alleging, that it ought not to hold plea of this injury, it arising in Wales or beyond sea; or because the land in question is of ancient demesne, and ought only to be demanded in the lord's court, &c. 2. To the disability of the plaintiff, by reason whereof he is incapable to commence or continue the suit; as, that he is an alien enemy, outlawed, excommunicated, attainted of treason or felony, under a præmunire, not in *rerum natura* (being only a fictitious person), an infant, a feme-covert, or a monk professed. 3. In abatement: which abatement is either of the writ, or the count, for some defect in one of them; as by misnaming the defendant, which is called a misnomer; giving him a wrong addition, as esquire instead of knight; or other want of form in any material respect. Or, it may be that the plaintiff is dead; for the death of either party is at once an abatement of the suit.

These pleas to the jurisdiction, to the disability, or in abatement, were formerly very often used as mere dilatory pleas, without any foundation in truth, and calculated only for delay; but now by stat. 4 and 5 Ann. c. 16. no dilatory plea is to be admitted without affidavit made of the truth thereof, or some probable matter shown to the court to induce them to believe it true. And with respect to the pleas themselves, it is a rule, that no exception shall be admitted against a declaration or writ, unless the defendant will in the same plea give the plaintiff a better; that is, show him how it might be amended, that there may not be two objections upon the same account.

All pleas to the jurisdiction conclude to the cognizance of the court; praying "judgment, whether the court will have further cognizance of the suit." Pleas to the disability conclude to the person; by praying "judgment, if the said A. the plaintiff ought to be answered." And pleas in abatement (when the suit is by original) conclude to the writ or declaration

by praying "judgment of the writ or declaration, and that the same may be quashed," *casetur*, made void, or abated: but if the action be by bill, the plea must pray "judgment of the bill," and not of the declaration; the bill being here the original, and the declaration only a copy of the bill.

When these dilatory pleas are allowed, the cause is either dismissed from that jurisdiction, or the plaintiff is stayed till his disability be removed; or he is obliged to sue out a new writ, by leave obtained from the court, or to amend and new-frame his declaration. But when, on the other hand, they are over-ruled as frivolous, the defendant has judgment of *respondet ouster*, or to answer over in some better manner. It is then incumbent on him to plead.

(2.) A plea to the action; that is, to answer to the merits of the complaint. This is done by confessing or denying it.

A confession of the whole complaint is not very usual; for then the defendant would probably end the matter sooner, or not plead at all, but suffer judgment to go by default. Yet sometimes after tender and refusal of a debt, if the creditor harasses his debtor with an action, it then becomes necessary for the defendant to acknowledge the debt, and plead the tender; adding, that he has always been ready, *tout temps prêt*, and is still ready, *encore prêt*, to discharge it: for a tender by the debtor and refusal by the creditor will in all cases discharge the costs, but not the debt itself; though in some particular cases the creditor will totally lose his money. But frequently the defendant confesses one part of the complaint (by a *cognovit actionem* in respect thereof), and traverses or denies the rest; in order to avoid the expence of carrying that part to a formal trial, which he has no ground to litigate. A species of this sort of confession is the payment of money into court: which is for the most part necessary upon pleading a tender, and is itself a kind of tender to the plaintiff; by paying into the hands of the proper officer of the court as much as the defendant acknowledges to be due, together with the costs hitherto incurred, in order to prevent the expence of any further proceedings. This may be done upon what is called a motion; which is an occasional application to the court by the parties or their counsel, in order to obtain some rule or order of court, which becomes necessary in the progress of a cause; and it is usually grounded upon an affidavit (the perfect tense of the verb *affido*), being a voluntary oath before some judge or officer of the court, to evince the truth of certain facts upon which the motion is grounded: though no such affidavit is necessary for payment of money into court. If, after the money is paid in, the plaintiff proceeds in his suit, it is at his own peril: for, if he does not prove more due than is so paid into court, he shall be nonsuited and pay the defendant's costs; but he shall still have the money so paid in, for that the defendant has acknowledged to be his due. To this head may also be referred the practice

of what is called a set-off; whereby the defendant acknowledges the justice of the plaintiff's demand on the one hand; but, on the other, sets up a demand of his own, to counterbalance that of the plaintiff, either in the whole or in part; as, if the plaintiff sues for ten pounds due on a note of hand, the defendant may set off nine pounds due to himself for merchandize sold to the plaintiff; and, in case he pleads such set-off, must pay the remaining balance into court.

Pleas that totally deny the cause of complaint are either the general issue, or special plea in bar.

1. The general issue, or general plea, is what traverses, thwarts, and denies at once the whole declaration, without offering any special matter whereby to evade it. As in trespass either *vi et armis*, or on the case, "*non culpabilis*, not guilty;" in debt upon contracts, "*nihil dedet*, he owes nothing;" in debt on bond, "*non est factum*, it is not his deed;" "on an *assumpsit*," "*non assumpsit*, he made no such promise." Or in real actions, "*nul tort*, no wrong done; *nul disseisin*, no disseisin;" and in a writ of right, the misprision is, that "the tenant has more right to hold than the demandant has to demand." These pleas are called the general issue, because, by importing an absolute and general denial of what is alleged in the declaration, they amount at once to an issue; by which we mean a fact affirmed on one side and denied on the other.

2. Special pleas in bar of the plaintiff's demands are very various, according to the circumstances of the defendant's case. As, in real actions, a general release or a fine; both of which may destroy and bar the plaintiff's title. Or, in personal actions, an accord, arbitration, conditions performed, nonage of the defendant, or some other fact which precludes the plaintiff from his action. A justification is likewise a special plea in bar.

To PLEACH. *v. a.* (*plesser*, French.) To bend; to interweave: not in use (*Shakspeare*).

To PLEAD. *v. n.* (*plaider*, French.) 1. To argue before a court of justice (*Gran.*). 2. To speak in an argumentative or persuasive way for or against; to reason with another (*Shaks.*). 3. To be offered as a plea (*Dryden*).

To PLEAD. *v. a.* 1. To defend; to discuss (*Shakspeare*). 2. To allege in pleading or argument (*Spenser*). 3. To offer as an excuse (*Dryden*).

PLEADABLE. *a.* (from *plead*.) Capable of being alleged in plea (*Dryden*).

PLEADER. *s.* (*plaideur*, French.) 1. One who argues in a court of justice (*Swift*). 2. One who speaks for or against (*Shakspeare*).

PLEADING. *s.* (from *plead*.) Act or form of pleading (*Swift*).

PLEADINGS. Pleadings, in general, signify the allegations of parties to suits when they are put into a proper and legal form; and are distinguished in respect to the parties who plead them, by the names of bars, replications, rejoinders, sur-rejoinder, rebutters, &c.; and

though the matter in the declaration or count does not properly come under the name of pleading, yet, being often comprehended in the extended sense of the word, it is generally considered under this head. This is the technical sense of the word pleading, which is vulgarly applied to the public speaking of the advocates in the courts. The necessity of reducing the proceedings into writing gives rise to a great deal of business amongst barristers, which is called special pleading, and those who are skilled in this are distinguished particularly as pleaders. Of late years persons under the degree of barristers have drawn pleadings which are afterwards signed by barristers. These persons take very low fees, but when called to the bar engross a great share of business. Their habits bring them closely connected with attorneys.

PLEA'SANCE. *s.* (*plaisance*, French.) Gayety; pleantry: obsolete (*Spenser*).

PLEA'SANT. *a.* (*plaisant*, French.) 1. Delightful; giving delight (*Psalms*). 2. Grateful to the senses (*Milton*). 3. Good-humoured; cheerful (*Addison*). 4. Gay; lively; merry (*Rogers*). 5. Trifling; adapted rather to mirth than use (*Locke*).

PLEA'SANTLY. *ad.* (from *pleasant*.) 1. In such a manner as to give delight. 2. Gayly; merrily; in good humour (*Claren.*). 3. Lightly; ludicrously (*Broome*).

PLEA'SANTNESS. *s.* (from *pleasant*.) 1. Delightfulness; state of being pleasant. 2. Gayety; cheerfulness; merriment (*Tillotson*).

PLEA'SANTRY. *s.* (*plaisanterie*, French.) 1. Gayety; merriment (*Addison*). 2. Sprightly saying; lively talk (*Addison*).

To PLEASE. *v. a.* (*placeo*, Lat. *plaire*, Fr.) 1. To delight; to gratify; to humour (*Pope*). 2. To satisfy; to content (*Shakspeare*). 3. To obtain favour from: to be pleased with, is to approve; to favour (*Milton*). 4. To be PLEAS-ED. To like. A word of ceremony (*Dryden*).

To PLEASE. *v. n.* 1. To give pleasure (*Milton*). 2. To gain approbation (*Hosea*). 3. To like; to choose (*Pope*). 4. To condescend; to comply (*Shakspeare*).

PLEA'SER. *s.* (from *please*.) One that courts favour.

PLEA'SINGLY. *ad.* (from *pleasing*.) In such a manner as to give delight (*Pope*).

PLEA'SINGNESS. *s.* (from *pleasing*.) Quality of giving delight.

PLEA'SEMAN. *s.* (*please* and *man*.) A pickthank; an officious fellow (*Shakspeare*).

PLEA'SURABLE. *a.* (from *pleasure*.) Delightful; full of pleasure (*Bacon*).

PLEASURE. *s.* (*plaisir*, French.) 1. Delight; gratification of the mind or senses. See **HAPPINESS**. 2. Loose gratification (*Shakspeare*). 3. Approbation (*Psalms*). 4. What the will dictates (*Shakspeare*). 5. Choice; arbitrary will (*Brown*).

To PLEASURE. *v. a.* (from the noun.) To please; to gratify (*Tillotson*).

PLEASUREFUL. *a.* (*pleasure* and *full*.) Pleasant; delightful: obsolete (*Abbot*).

PLEASURE-GROUND, in gardening, any kind of ornamented ground surrounding a mansion or other residence. Whence the term comprehends all the embellishing compartments or divisions of ground and plantation, such as lawns, plantations of trees and shrubs, flower compartments, walks, pieces of water, &c. whether situated wholly within the space generally considered as proper pleasure-ground, or extended over ha-has or sunk fences, or by other communications to the adjacent fields, parks, paddocks, or out-grounds.

In designs for pleasure-grounds, modern improvements reject all formal works, as long straight walks, regular intersections, square grass-plots, corresponding parterres, quadrangular and angular spaces, inclosed with high clipped hedges, as well as all other uniformities. Instead of which, open spaces of grass ground of varied forms and dimensions, and winding walks, all bounded with plantations of trees, shrubs, flowers in various clumps, and other distributions are picturesquely exhibited in a variety of rural forms; as curves, projections, openings and closings, in imitation of natural assemblages, each of these being laid open to the walks and lawns. A broad expansive lawn of grass is usually placed immediately in the front of the mansion or main residence; sometimes widely extended in open space on both sides, to admit of a spreading prospect; and sometimes more contracted towards the habitation, widening gradually outward, and having each side embellished with shrubby plantations, groves, thickets, &c. in clumps; and in other parts in sweeps, curves, and projections towards the lawn, &c. with breaks or openings of grass spaces at intervals between the plantations; and serpentine gravel walks, winding under the shade of the trees: extended plantations being also carried round the outer boundary of the ground, in various openings and closings, having also gravel walks winding through them for shady retirement; while in the interior divisions of the ground serpentine walks take a meandering line, and elegant grass-plots occasionally open, ranging in various directions, all bordered with shrubberies, and other tree and shrub plantations, flower compartments, &c. each being so distributed as continually to give a change of scene and object.

The general intention therefore of modern pleasure-grounds is to unite the diversified beauties of art and nature; and if the surface be marked with inequalities and irregularities, an advantage is taken even of these deviations from uniformity, and instead of our being at the expense of squaring or levelling them, the natural forms are humoured, slightly smoothed where ruggedness would be inappropriate with the general character, and even increased in prominence, where a bold projecting and formidable contrast is demanded, or may be picturesquely introduced. The grand point of attention being at all times to take care that the whole range of the prospect is not exhausted at one view, and to give to every object, and

especially to every distant object, a perpetual change and novelty of shape and impression, by disclosing them in different attitudes or under different aspects.

It is impossible to lay down any precise plan upon this subject, since the arrangement must altogether depend upon the character and extent of the natural landscape, and the taste and judgment of the designer.

The mansion itself, however, should if possible be always erected in a situation somewhat elevated, or on the side of a moderate slope. Yet when this is not practicable,

E'en in the deep unseen, unseeing dell,

in the midst of flats and plains, an artist of taste and real genius may contrive to call forth a considerable range of pleasing and picturesque effect; relinquishing, however, as in such situations he ought uniformly to do, all attempts at the grand and the magnificent, letting the modest take the place of the bold, and the beautiful that of the sublime. Such pleasure-grounds are common to the midland counties of this country, and in many instances produce in the mind, not indeed so striking and instantaneous an effect as landscapes full of contrast, and gigantic abruptness of scenery, but often sweeter and more durable; full of repose and tranquillity.

PLEBEIAN, any person of the rank of the common people. The word is chiefly employed in speaking of the ancient Romans, who were divided into senators, patricians, and plebeians. The distinction was made by Romulus.

PLEBEI'AN. *a.* 1. Popular; consisting of mean persons (*King Charles*). 2. Belonging to the lower ranks (*Milton*). 3. Vulgar; low; common (*Bacon*).

PLECTANTHRUS, in botany, a genus of the class didynamia, order gymnospermia. Calyx with the upper division larger; corol reversed, ringent; the tube either gibbous or spurred upwards. Six species; natives of Asia or Africa.

PLECTRONIA, in botany, a genus of the class pentandria, order monogynia. Petals five, inserted into the throat of the calyx; berry two-seeded, inferior. One species; a tree of the Cape, with lance-ovate, very entire leaves; corymbed flowers.

PLECTRUM. The quill formerly used instead of the ends of the fingers in agitating the strings of various musical instruments.

PLEDGE. *s.* (*pleige*, French; *pieggio*, Ita.) 1. Any thing put to pawn. 2. A gage; any thing given by way of warrant or security; a pawn (*Rowe*). 3. A surety; a bail; an hostage (*Raleigh*).

To **PLEDGE**. *v. a.* (*pleiger*, French; *piegiare*, Italian.) 1. To put in pawn (*Pope*). 2. To give as warrant or security. 3. To secure by a pledge (*Shakspeare*).

To **PLEDGE**, in drinking, denotes to warrant, or be surety to one, that he shall receive no harm while he is taking his draught. The phrase is referred by our antiquaries to the

practice of the Danes heretofore in England, who frequently used to stab or cut the throats of the natives while they were drinking.

PLEDGES OF GOODS FOR MONEY. See **PAWN**.

PLEDGERY, or **PLEGGERY**, in law, suretiship, or an undertaking or answering for another.

PLEDGET, **BOLSTER**, or **COMPRESS**, in surgery, a kind of flat tent laid over a wound, to imbibe the superfluous humours, and to keep it clean.

PLEGORHIZA, in botany, a genus of the class enneandria, order monogynia. Calyxless; corol one-petalled; capsule one-celled, one seeded. One species; a native of Chili, with tufted oval petioled root-leaves, and terminal flowers.

PLEIADES, in fabulous history, the seven daughters of Atlas king of Mauritania and Pleione, were thus called from their mother. They were Maia, Electra, Taygete, Asterope, Merope, Halcyone, and Celeno; and were also called Atlantides, from their father Atlas. These princesses were carried off by Busiris king of Egypt; but Hercules having conquered him, delivered them to their father: yet they afterwards suffered a new persecution from Orion, who pursued them five years, till Jove, being prevailed on by their prayers, took them up into the heavens, where they form the constellation which bears their name.

PLEIADES, in astronomy, an assemblage of seven stars, in the neck of the constellation Taurus. They are thus called from the Greek *πλεῖν, navigare*, to fail; as being terrible to mariners, by reason of the rains and storms that frequently rise with them. The Latins called them *vergilia* from *ver*, spring; because of their rising about the time of the vernal equinox. The largest is of the third magnitude, and is called lucida pleiadum.

PLEIADES OF POETS. See **LYCOPHRON**.

PLEIONE, one of the Oceanides, who married Atlas, king of Mauritania, by whom she had twelve daughters, and a son called Hyas. Seven of the daughters were changed into a constellation called Pleiades, and the rest into another, called Hyades.

PLENARILY. *ad.* (from *plenary*.) Fully; completely (*Ayliffe*).

PLENARINESS. *s.* (from *plenary*.) Fullness; completeness.

PLENARY. *a.* (from *plenus*, Lat.) Full; complete (*Watts*).

PLENARY. *s.* Decisive procedure (*Ayliffe*).

PLENILUNARY. *a.* (from *plenilunum*, Lat.) Relating to the full moon (*Brown*).

PLENIPOTENCE. *s.* (from *plenus* and *potentia*, Lat.) Fulness of power.

PLENIPOTENT. *a.* (*plenipotens*, Latin.) Invested with full power (*Milton*).

PLENIPOTENTIARY. *s.* (*plenipotentiaire*, French.) A negotiator invested with full power (*Stillingfleet*).

PLENIST. *s.* (from *plenus*, Lat.) One that holds all space to be full of matter (*Boyle*).

PLENTITUDE. *s.* (*plenitudo*, from *plenus*, G G 2

Latin; *plenitudo*, French.) 1. Fulness; the contrary to vacuity (*Bentley*). 2. Repletion; animal fulness; plethory (*Arbuthnot*). 3. Exuberance; abundance (*Bacon*). 4. Completeness (*Prior*).

PLENTEOUS. *a.* (from *plenty*.) 1. Copious; exuberant; abundant (*Milton*). 2. Fruitful; fertile (*Genesis*).

PLENTEOUSLY. *ad.* Copiously; abundantly; exuberantly; plentifully (*Shakspeare*).

PLENTEOUSNESS. *s.* (from *plenteous*.) Abundance; fertility; plenty (*Genesis*).

PLENTIFUL. *a.* (*plenty* and *full*.) Copious; abundant; exuberant; fruitful (*Raleigh*).

PLENTIFULLY. *ad.* (from *plentiful*.) Copiously; abundantly (*Addison*).

PLENTIFULNESS. *s.* (from *plentiful*.) The state of being plentiful; abundance; fertility.

PLENTY. *s.* (from *plenus*, Latin, full.) 1. Abundance; such a quantity as is more than enough (*Locke*). 2. Fruitfulness; exuberance (*Thomson*). 3. It is used, I think barbarously, for *plentiful* (*Shakspeare*). 4. A state in which enough is had and enjoyed (*Joel*).

PLENUM, in physics, denotes, according to the Cartesians, that state of things wherein every part of space is supposed to be full of matter, in opposition to a vacuum, which is a space supposed devoid of all matter.

PLENUS FLOS, a full flower; a term expressive of the highest degree of luxuriance in flowers. Such flowers, although the most delightful to the eye, are both vegetable monsters, and, according to the sexualists, vegetable eunuchs; the unnatural increase of the petals constituting the first; the consequent exclusion of the stamina or male organs, the latter.

PLEONASM. *s.* (*pleonasmus*, Latin.) A figure of rhetoric, by which more words are used than are necessary usually, for the purpose of deepening the impression.

PLESH. *s.* (A word used by *Spenser* instead of *plash*.) A puddle; a boggy marsh.

PLESHEY, a village in Essex, seven miles N. by W. of Chelmsford. It was the seat of the lord high constable of England, from the earliest times of that office to the year 1400. On the site of his castle is now a brick farm-house; and here are the remains of an ancient fortification, consisting of a mount, of an oval form, surrounded by an area that contains about two acres, and is bounded by a rampart and ditch, over which is a brick bridge.

PLESSE, a town of Silesia, with a castle, seated on the Vistula, 36 miles E. of Troppaw. Lon. 18. 36 E. Lat. 50. 0 N.

PLETHORA. (*πλεθωρα*; from *πλεωω*, to fill.) Fulness of vessels. A redundancy of blood.

PLETHORETIC. *a.* (from *plethora*.) Having a full habit.

PLETTENBERG, a town of Westphalia, in the county of Mark, governed by its own magistracy. It is situate on the Else and

Oester, 28 miles S. of Ham. Lon. 7. 48 E. Lat. 51. 8 N.

PLEVIN. *s.* (*plevine*, Fr. *plevina*, law Lat.) In law, a warrant or assurance.

PLEURA. (*πλευρα*.) A membrane which lines the internal surface of the thorax, and covers its viscera. It forms a great process, the mediastinum, which divides the thorax into two cavities. Its use is to render the surface of the thorax moist by the vapour it exhales. The cavity of the thorax is every where lined by this smooth and glistening membrane, which is in reality two distinct portions or bags, which by being applied to each other laterally, form the septum called mediastinum: this divides the cavity into two parts, and is attached posteriorly to the vertebræ of the back; and anteriorly to the sternum. But the two laminae of which this septum is formed, do not every where adhere to each other; for at the lower part of the thorax they are separated to afford a lodgement to the heart, and at the upper part of the cavity they receive between them the thymus. The pleura is plentifully supplied with arteries and veins from the internal mammary, and the intercostals. Its nerves, which are very inconsiderable, are derived chiefly from the dorsal and intercostal nerves. The surface of the pleura, like that of the peritonæum and other membranes lining cavities, is constantly bedewed with a serous mixture, which prevents adhesions of the viscera. The mediastinum, by dividing the breast into two cavities, obviates many inconveniences to which we should otherwise be liable. It prevents the two lobes of the lungs from compressing each other when we lie on one side, and consequently contributes to the freedom of respiration, which is disturbed by the least pressure on the lungs. If the point of a sword penetrate between the ribs into the cavity of the thorax, the lungs on that side cease to perform their office, because the air being admitted through the wound, prevents the dilatation of that lobe, while the other lobe, which is separated from it by the mediastinum, remains unhurt, and continues to perform its functions as usual.

PLEURISY. *s.* (*πλευριτις*.) An inflammation of the pleura, or membrane that lines the cavity of the breast (*Quincy*).

PLEURITICAL. *a.* (from *pleurisy*.) 1. Diseased with a pleurisy (*Arb.*). 2. Denoting a pleurisy (*Wiseman*).

PLEURITIS. (*πλευριτις*, from *πλευρα*, the membrane lining the lungs.) Pleurisy, or inflammation of the pleura. A species of pneumonia of Cullen. See **PNEUMONIA**. In some instances the inflammation is partial, or affects one place in particular, which is commonly on the right side; but in general, a morbid affection is communicated throughout its whole extent. The disease is occasioned by exposure to cold, and by all the causes which usually give rise to all inflammatory complaints; and it attacks chiefly those of a vigorous constitution and plethoric habit. In

consequence of the previous inflammation, it is apt at its departure to leave behind a thickening of the pleura, or adhesions to the ribs and intercostal muscles, which either lay the foundation of future pneumonic complaints, or render the patient more susceptible of the changes in the state of the atmosphere than before.

It commences with an acute pain in the side, which is much increased by making a full inspiration, and is accompanied by flushing in the face, increased heat over the whole body, rigours, difficulty of lying on the side affected, together with a cough and nausea, and the pulse is hard, strong, and frequent, and vibrates under the finger when pressed upon, not unlike the tense string of a musical instrument. If blood is drawn and allowed to stand for a short time, it will exhibit a thick sily or buffy coat on its surface. If the disease be neglected at its onset, and the inflammation proceeds with great violence and rapidity, the lungs themselves become affected, the passage of the blood through them is stopped, and the patient is suffocated; or from the combination of the two affections, the inflammation proceeds on to suppuration, and an abscess is formed. The prognostic in pleurisy must be drawn from the severity of the symptoms. If the fever and inflammation have run high, and the pain should cease suddenly, with a change of countenance and a sinking of the pulse, great danger may be apprehended; but if the heat and other febrile symptoms abate gradually; if respiration is performed with greater ease and less pain, and a free and copious expectoration ensues, a speedy recovery may be expected.

The appearances on dissection are much the same as those mentioned under the head of pneumonia, viz. an inflamed state of the pleura, connected with the lungs, having its surface covered with red vessels, and a layer of coagulated lymph lying upon it, adhesions too, of the substance of the lungs to the pleura. Besides these, the lungs themselves are often found in an inflamed state, with an extravasation either of blood or coagulated lymph in their substance. Tubercles and abscesses are likewise frequently met with.

PLEURODYNIA. (*πλευροδυνία*; from *πλευρα*, and *δυνι*, pain.) A pain in the side, from a rheumatic affection of the pleura.

PLEURONECTES. Flat-fish. In zoology, a genus of the class pisces, order thoracica. Head small; eyes spherical, both on the same side of the head, and near each other; mouth arched; jaws unequal, toothed; gill-membrane with from four to seven rays; the cover mostly of three laminae; body convex, and coloured above; flat and paler beneath; vent near the head.

This genus, including those which are usually denominated flat-fishes, embraces the turbot, sole, holibut, plaice, flounder, pearl, and whiff. These swim constantly obliquely, and reside at the bottom of the water, from their wanting the air-bladder; they often bury

themselves in the sand as far as the head, by which they escape the jaws of the more rapacious tribes: the eyes are covered with a nictitant membrane; nostrils double and contiguous; belly without ribs; fins soft and mostly with simple rays, the ventral and pectoral long; the tail generally rounded, with bifid rays. Twenty-nine species, thus subdivided:

A. Eyes both on the right side of the head.

Seventeen species.

B. Eyes both on the left side of the head.

Twelve species.

The species of this genus are scattered through the seas of the globe generally: chiefly, however, those of Europe and America. About twelve species are found near our own coasts. The following are those most worthy of notice.

1. *P. platessa*. Plaice. Body smooth; behind the left eye a row of six tubercles reaching to the lateral line: head covered with firm scales, each deposited in its proper bed; eyes moderate, pupil blueish, iris greenish-yellow; mouth small; teeth small, obtuse; tail scaly at the base, with all the rays longer than the membrane. Inhabits British and other European seas; grows to sixteen pounds weight; body often varied with brown and cinereous, with large bright orange spots, beneath white; flesh good.

2. *P. hippoglossus*. Holibut. Body perfectly smooth; tail lunate.

This species is called in Scotland turbot, though different from the fish known in England by that name. It is the largest of all the aquatic animals except the whale tribe, and is sometimes found on our shores three hundred pounds weight, while those in the seas of Iceland and Newfoundland greatly exceed even that size. In Greenland they are also caught of a prodigious bulk, with the hook and line, off these bold shores: where they are cut up into large slips, and dried for food to the inhabitants. The holibut is also common in the London market; but where there is such an abundant variety to choose, they are deemed a coarse unsavoury fish, excepting the part which adheres to the side fins, which is fat and luscious.

The colour above is an obscure green, bordering upon black; that of the belly a pure white. The scales are small, and the body all over free from spines; even the edges of the fins have no asperity from the projection of the rays. The eyes are upon the left side of the mouth, and the right of the animal. The fin which runs along the back begins above the eyes, and terminates about two inches from the tail; that upon the belly has its origin about seven inches from the point of the rostrum, and terminates in the same manner. There are two pectoral fins and six small ones on the belly.

3. *P. maximus*. Turbot. Body rough. This species is an excellent food, and grows to a great size, weighing from twenty to thirty pounds. The skin is entirely destitute of scales, but is granulated, and has different asperities

here and there dispersed over it. The whole upper part of the body, together with the head and fins, is cinereous, and thick set with a variety of black spots. The jaws are not furnished with a single row of teeth, as in the other species, but are armed with a vast number of small ones; as also the palate. The eyes are placed on the left side, not so near the edge of the back, nor so close to one another, as in the rest. The dorsal fin takes its origin farther forward than usual, beginning near the upper part of the mouth, and extending till it nearly reaches the tail.

The turbot fishery is carried on to the greatest extent on the north coasts of England and of Holland. These fishes are most successfully caught by the hook and line; the method practised by staked nets being very uncertain. The fishermen of Scarborough are most expert in this business. They go out in large cobbles, with three men in each; and every fisher has three lines, furnished with two hundred and eighty hooks apiece. The lines, before shooting, are all joined together, when they extend about three miles, and are fastened with buoys and anchors. They are drawn at every turn of the tide, the rapidity of the current preventing at any other time.

4. *P. solea*. Sole. Body oblong, rough; upper jaw longer. Inhabits European and Mediterranean seas: sometimes above two feet long; body narrow, above olive; scales small, hard, denticulate, very firmly adhering to the skin: flesh good, and next to the turbot considered as the most delicate of the whole tribe: those of moderate size are in general most esteemed. The sole delights in lying at the bottom of the coasts which it frequents, preying on small shell-fishes, spawn, sea-insects, &c. and is generally taken by the trawl net. The chief fishery, according to Mr. Pennant, is at Brixham in Torbay.

5. *P. flossus*. Flounder. Lateral line rough; short spines on the right side of the fins. Inhabits European seas, and even enters rivers far above the salt waters; seldom exceeds six pounds weight; body covered with thin oblong scales, firmly sticking to the skin; above pale-brown with dirty yellow spots, beneath white shaded with brownish.

6. *P. limanda*. Dab. Scales small, ciliate; spinules at the root of the dorsal and anal fins with obtuse teeth. Inhabits European seas; less and thinner than the flounder; feeds on worms and insects, especially small crabs; spawns in June; body mucous, above dark liver-colour, beneath white; scales soft, oblong, sticking firmly to the body; flesh very good.

7. *P. lævis*. Smear-dab. Brown, with obscure yellow spots, beneath white, with five large dusky spots; scales smooth; dorsal fin seventy-five-rayed. Inhabits Europe; one and a half foot long; flesh very good.

8. *P. rhombus*. Pearl. Body smooth. Inhabits the European seas; is the broadest of its size except the turbot; body covered with small scales, deep-brown with dirty yellow

spots, beneath white; flesh very good, but inferior to the turbot.

9. *P. passer*. Whiff. Lateral line much curved, prickly. Inhabits European seas; hardly a foot long; body oblong, smooth, covered with thin scales, above varied with cinereous and yellow, beneath white; flesh very good.

PLEURO-PNEUMONIA. (πλευρο-πνευμονία; from πλευρα, and πνευμονια, an inflammation of the lungs.) An inflammation of the lungs and pleura.

PLEXIPPUS. The most remarkable of this name was a son of Theseus, brother to Althæa, the wife of Ceneus. He was killed by his nephew Meleager, in hunting the Calydonian boar. His brother Toxens shared his fate.

PLEXUS. (from *plector*, to plait or knit.) A net-work of vessels. The union of two or more nerves is also called a plexus.

PLEXUS (Cardiac). See **CARDIAC PLEXUS**.

PLEXUS (Choroides). See **CHOROID PLEXUS**.

PLEXUS (Oesophageal). See **OESOPHAGEAL**.

PLEXUS (Pulmonic). See **PULMONIC PLEXUS**.

PLEYBERG, a town of Germany, in Carinthia, seated on the Feistez, at the foot of a mountain, 25 miles E. by S. of Clagenfurt.

PLIABLE. *a.* (*pliable*, from *plier*, Fr.) 1. Easy to be bent; flexible (*South*). 2. Flexible of disposition; easy to be persuaded.

PLIABLENESS. *s.* (from *pliable*.) 1. Flexibility; easiness to be bent. 2. Flexibility of mind (*South*).

PLI'ANCY. *s.* (from *pliant*.) Easiness to be bent (*Addison*).

PLI'ANT. *a.* (*pliant*, French.) 1. Bending; tough; flexible; flexible; lithe; limber (*Addison*). 2. Easy to take a form (*Dryd.*). 3. Easily complying (*Bacon*). 4. Easily persuaded (*South*).

PLIANT MEALY TREE. See **VIBURNUM**.

PLI'ANTNESS. *s.* (from *pliant*.) Flexibility; toughness (*Bacon*).

PLICA POLONICA. (from *plico*, to entangle. This disease is commonly distinguished by the adjective *polonica*, it being peculiar to the inhabitants of Poland and Lithuania.) Trichoma. A disease of the hairs, in which they become long and coarse, and matted and glued into inextricable tangles. It is peculiar to Poland and Tartary, and generally appears during the autumnal season.

PLICATE, in botany, plaited: applied to the leaves of plants.

PLICATION. **PLI'CATURE.** *s.* (*plicatura*, from *plico*, Latin.) Fold; double.

PLIERS. *s.* (from *ply*.) An instrument by which any thing is laid hold on to bend it.

To PLIGHT. *v. a.* (*plichten*, Dutch.) 1. To pledge; to give as surety (*Shakspeare*). 2. (from *plico*, Lat.) To braid; to weave (*Spenser*).

PLIGHT. *s.* (*plhtz*, Saxon.) 1. Condition;

state (*Shakspeare*). 2. Good case (*Tusser*). 3. Pledge; gage (from the verb.) (*Shakspeare*). 4. (from *to plight*.) A fold; a pucker; a double; a puffle; a plait (*Spenser*).

PLINIA, in botany, a genus of the class icosandria, order monogynia. Calyx four or five-parted; petals four or five; drupe superior, grooved. One species only; an American tree, with pinnate leaves; scattered sessile flowers; and an eatable fruit.

PLINTH. *s.* (πλινθίς.) In architecture, a flat square member, in the form of a brick. It is used as the foundation of columns, being that flat square table, under the moulding of the base and pedestal at the bottom of the whole order. It seems to have been originally intended to keep the bottom of the original wooden pillars from rotting.

PLINTH OF A STATUE, &c. is a base, either flat, round, or square, that serves to support it.

PLINTH OF A WALL, denotes two or three rows of bricks advancing out from a wall; or, in general, any flat high moulding, that serves in a front wall to mark the floors, to sustain the eaves of a wall, or the larmier of a chimney.

PLINY the Elder (*Plinius Secundus*), was born at Verona, of a noble family. He distinguished himself in the field, and, after he had been made one of the augurs at Rome, he was appointed governor of Spain. In his public character he did not neglect the pleasures of literature; the day was employed in the administration of the affairs of his province, and the night was dedicated to study. If his literary pursuits made him forget public affairs, his prudence, and his abilities, made him known and respected. He was courted and admired by the emperors Titus and Vespasian. As he was at Misenum, where he commanded the fleet, which was then stationed there, he was surprised at the sudden appearance of a cloud of dust and ashes which issued from mount Vesuvius. His curiosity then led him to make some observation thereon, and having approached the mountain, he was, before he could effect an escape, suffocated by the thick vapours that surrounded him, and the insupportable stench of sulphureous matter. His body was found three days after, and decently buried. This memorable event happened in the 79th year of the Christian era, and the 56th year of his age. Of the works which he composed none are extant but his *Natural History* in 37 books. It treats of the stars, the heavens, wind, rain, hail, minerals, trees, flowers, and plants, besides the account of all living animals, birds, fishes, and beasts; a geographical description of every place on the globe, and an history of every art and science, of commerce and navigation, with their rise, progress, and several improvements.

Of the *Natural History* there have been several editions. The editio princeps, printed at Venice in 1469, is one of the most beautiful and valuable publications of the 15th century. Jenson's edition, printed at Venice in 1472, is

very splendid and curious, but it is not free from interpolations. The Aldine edition of Paul Manutius, in 4 vols. 8vo. printed at Venice in 1536, is characterised by De Bure, as "Edition fort belle, peu commune, et recherchée avec raison, de ceux qui aiment les éditions de cet imprimeur." The edition of Crispinus printed at Geneva, in 1631, is called by Dibdin "a work beyond all praise." Besides these, the Elzivir variorum edition of 1669, father Harduin's, of 1723, the Leipsic edition of 1778—91, and those of Brotier and the Bipont editors, are very useful and esteemed publications.

PLINY the Younger, or *C. Cæcilius*, was son of *L. Cæcilius* by the sister of *Pliny the Elder*. He was adopted by his uncle, whose name he assumed. He received the greatest part of his education under *Quintilian*, and, at the age of 19, he appeared at the bar, where he distinguished himself so much by his eloquence, that he, and *Tacitus*, were reckoned the two greatest orators of their age. He published many of his harangues and orations, which have been lost. He presided over *Pontus* and *Bithynia*, in the office of pro-consul, and, by his philanthropy, the persecution begun against the christians of his province was stopped, when he declared to the emperor that the followers of *Christ* were a meek and inoffensive sect of men. If he rendered himself popular in his province, he was not less respected at Rome, as being the friend of the poor, and the patron of learning. He died in the 52d year of his age, *A. D.* 113. He had written an history of his own times, which is lost. Some suppose, but falsely, that *Pliny* wrote the lives of illustrious men, universally ascribed to *Cornelius Nepos*. He also wrote poetry, but his verses have all perished, and nothing of his learned works remains but his panegyric on the emperor *Trajan*, and 10 books of letters, which are written with elegance and great purity. These letters are esteemed by some equal to the voluminous epistles of *Cicero*.

The editio princeps of the Letters in folio, date 1471, without name of printer or place, is a very magnificent work. The Naples edition of 1476 is rare and very beautiful. *H. Stephens'* editions, Paris 1581, Geneva 1591, are elegant and valuable. The Elzivir edition of 1640 contains also the Panegyric, and is an accurate and beautiful little work. Besides these, the editions of *Thomasius*, in 1675, of *Longolius*, in 1734, and *Henry Homer's*, published by *Payne*, in 1790, are much and deservedly esteemed. The Epistles have also been elegantly translated by *Orrery* and *Melmoth*. Of the Panegyric we need only mention the editio optima by *Swarz*, published at Nuremberg in 1746. Its great merits are universally known and acknowledged amongst classical scholars.

PLISTHENES, a son of *Atræus*, king of *Argos*, father of *Menelaus* and *Agamemnon*, according to *Hesiod* and others. *Homer*, however, calls *Menelaus* and *Agamemnon* sons of

Atræus. The father died very young, and the two children were left in the house of their grandfather, who took care of them and instructed them. From his attention to them, Atræus was universally acknowledged their protector and father.

PLISTOANAX and **PLISTONAX**, son of Pausanias, was general of the Lacedæmonian armies in the Peloponnesian war. He was banished from his kingdom of Sparta for 19 years, and was afterwards recalled by order of the oracle of Delphi. He reigned 58 years.

PLOCAMA, in botany, a genus of the class pentandria, order monogynia. Calyx five-toothed, superior; corol campanulate, five-cleft; berry three-celled, the cells one-seeded. One species, a pendulous plant of the Canaries.

PLOCKSKO, a town of Poland, capital of a palatinate of the same name, with a castle, and a bishop's see. It is seated on a hill, near the Vistula, 45 miles E.S.E. of Uladislav, and 75 N.W. of Warsaw. Lon. 19. 29 E. Lat. 52. 46 N.

To PLOD. *v. n.* (*ploeghen*, Dutch. *Skinner.*) 1. To toil; to toil; to drudge; to travel. 2. To travel laboriously (*Shakspeare*). 3. To study closely and dully (*Hudibras*).

PLODDER. *s.* (from *plod*.) A dull heavy laborious man (*Shakspeare*).

PLOEN, a town of Lower Saxony, in the duchy of Holstein, capital of a principality of the same name. It is seated on the N. side of a lake, 22 miles N.W. of Lubec. Lon. 10. 20 E. Lat. 54. 11 N.

PLOERMEL, a town of France, in the department of Morbihan, 27 miles N.E. of Vannes. Lon. 2. 30 W. Lat. 47. 57 N.

PLOMO, in metallurgy, is a name given by the Spaniards, who have the care of the silver-mines, to the silver-ore, when found adhering to the surface of stones, and when it incrusts their cracks and cavities like small and loose grains of gunpowder. Though these grains be few in number, and the rest of the stone have no silver in it, yet they are always very happy when they find it, as it is a certain token that there is a rich vein somewhere in the neighbourhood.

PLOT. *s.* (*plotz*, Saxon.) 1. A small extent of ground (*Tusser*). 2. A plantation laid out (*Sidney*). 3. A form; a scheme; a plan (*Spenser*). 4. A conspiracy; a secret design formed against another (*Daniel*). 5. An intrigue; an affair complicated, involved, and embarrassed (*Roscommon*). 6. Stratagem; secret combination to an ill end (*Milton*). 7. Contrivance; deep reach of thought.

To PLOT. *v. n.* (from the noun.) 1. To form schemes of mischief against another (*Dryden*). 2. To contrive; to scheme (*Wotton*).

To PLOT. *v. a.* 1. To plan; to contrive (*Dryden*). 2. To describe according to ichnography.

PLOT (Robert), a learned antiquary, born at Sutton Barn, Kent, in 1641, and educated at Oxford, where he took his degree of LL.D. in 1671. He was secretary to the royal society,

and published their philosophical transactions from No. 143 to 166 inclusive: he was professor of chemistry at Oxford; keeper of the Ashmolean Museum, and historiographer to James II. also Mowbray herald extraordinary. He wrote the natural history of Oxfordshire and Staffordshire, in folio, besides several pieces in the philosophical transactions. He died of the stone in 1696.

PLOTINA POMPEIA, a Roman lady who married Trajan while a private man. She distinguished herself by her humanity, and liberal offices to the poor and friendless. She accompanied Trajan in the east, and upon her return to Rome with the ashes of her husband, she still enjoyed all the honours of a Roman empress under Adrian. At her death, A. D. 122, she was ranked among the gods, and received divine honours.

PLOTINOPOLIS, a town of Thrace, built by the emperor Trajan, and called after Plotina, the founder's wife.—Another in Dacia.

PLOTINUS, a Platonic philosopher of Lycopolis in Egypt. He was for eleven years a pupil of Ammonius the philosopher, after which he determined to visit India and Persia to receive information. He accompanied Gordian in his expedition into the east, but was obliged to save himself by flight, and the following year he retired to Rome, where he publicly taught philosophy. His school was frequented by people of every sex, age, and quality. He was the favourite of all the Romans; and while he charmed the populace by the force of his eloquence, and the senate by his doctrines, the emperor Gallienus courted him, and admired the extent of his learning. The philosopher having at last become helpless and infirm, died A. D. 270, in the 66th year of his age. His writings have been collected by his pupil Porphyry. They consist of 54 different treatises divided into six equal parts, written with great spirit and vivacity; but the reasonings are abstruse, and the subjects metaphysical.

Ficinus is the principal editor of Plotinus: the only editions we have heard of are those of 1492, 1580, and 1615.

PLOTTER. *s.* (from *plot*.) 1. Conspirator (*Dryden*). 2. Contriver (*Shakspeare*).

PLOTTING, among surveyors, is the art of laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, &c. and a chain. In surveying with the plain table, the plotting is saved; the several angles and distances being laid down on the spot, as fast as they are taken. (See **PLAIN-TABLE**.) But, in working with the theodolite, semicircle, or circumferentor, the angles are taken in degrees; and the distances in chains, and links, so that there remains an after-operation to reduce these members into lines, and so to form a draught, plan, or map; this operation is called plotting. Plotting then is performed by means of two instruments, the protractor and plotting scale. By the first, the several angles observed in the field with a theodolite, or the like, and entered

down in degrees in the field book, are protracted on paper in their just quantity. By the latter, the several distances measured with the chain, and entered down in the like manner in the field book, are laid down in their just proportion. See SURVEYING.

PLOTTING-SCALE, a mathematical instrument, usually of wood, sometimes of brass, or other matter; and either a foot or half a foot long. On one side of the instrument are seven several scales, or lines, of equal parts, to enable the plotter to lay down his dimensions of different sizes.

PLOTUS. Darter. In zoology, a genus of the class aves, order anseres. Bill straight, pointed, toothed; nostrils a little slit near the base; face and chin naked; legs short, all the toes connected. These have a small head and long, slender neck, and are chiefly seen in southern climates; they live principally on fishes, which they take by darting forward the head while the neck is contracted like the body of a serpent. Three species, as follow:

1. *P. aninga*. White-bellied darter. Head smooth; belly white; head, neck, and breast, reddish-grey; body above black, the scapular feathers with a white spot in the middle; tail-feathers twelve, broad, long; legs yellowish-ash. Inhabits Brazil; two feet ten inches long; builds on trees, and is hardly ever seen on the ground; when at rest, sits with the head drawn in between the shoulders; flesh oily and rancid.

2. *P. melanogaster*. Black-bellied darter. Head smooth; belly black. Inhabits Ceylon and Java; about three feet long. There are three or four other varieties from variation of colour, found in Cayenne and up the Senegal.

3. *P. Surinamensis*. Surinam darter. Head crested; belly white. Inhabits Surinam; thirteen inches long; is domesticated; and feeds on fishes, and insects, especially flies, which it catches with great dexterity: is very active.

PLOTZKAU, a town of Upper Saxony, in the duchy of Anhalt Bernberg, 24 miles W.S.W. of Dessau. Lon. 11. 45 E. Lat. 51. 48 N.

PLOVER, in ornithology. See **CHARADRIUS**.

PLOVER (Bastard). See **TRINGA**.

PLOUGH, in agriculture, a machine for breaking or turning up the soil, by the draught of cattle; and which, in general, consists of a train or carriage, furnished with two large irons (the one being pointed, while the other has a sharp edge), that serve both to cut or open, and also to draw furrows in the land.

"Ye generous Britons, venerate the plough,
And o'er your hills and long withdrawing vales,
Let autumn spread her treasures to the sun."

THOMSON.

No implement has more essentially contributed to the comforts of mankind than the plough; for without this contrivance, much time, labour, and expence, would be wasted in digging the ground, and preparing it for the reception of seed. Hence, ingenious men have invented a variety of ploughs, many of which are at present

employed by British farmers; and the more important of which we have already noticed in the article **HUSBANDRY**. We shall in this place therefore only add a few observations that have occurred to us since that article was composed.

The *Rotherham plough*, independently of Mr. Cooke's improvement already noticed in the article referred to, has been otherwise improved by Mr. Small, of Rosebank; who, we understand, has obtained a patent for his contrivance. In its present state, the wood-work is composed of ash or elm; and the plough differs from that commonly used, chiefly in the bridle, with which it is furnished at the end of the beam: this enables the ploughman to give the implement a more effectual power of action, and also by means of certain holes that are made in the beam, to cut the soil to a greater or less depth, as occasion may require. Another peculiarity that distinguishes this from the common plough, consists in the coulter and share, which are so constructed, and fixed, as to cut off the new furrow, without tearing it. Lastly, according to Mr. Small's plan, the mould-board being a plate of cast-iron, is so curved as to make less resistance to the earth turned up, and consequently requires a smaller force to draw it, than the common ploughs; while the furrow is gradually laid over to its proper position.—This plough is not provided with wheels; is light and convenient; it costs, we believe, from 40 to 50s.; and deserves to be introduced into the southern counties.

The *Kentish turn-wrest plough* consists of an oak beam, about ten feet in length, five inches in depth, and four inches in breadth; to the end of which is tenoned a foot, or piece of timber ($3\frac{1}{4}$ feet long, 4 inches thick, and $3\frac{1}{2}$ inches broad) that is mortised at the bottom, to the end of the chep. The handles are fixed on the top of the beam, through which, at the distance of two feet five inches from the foot, is passed a sheath of oak, seven inches in width, and an inch and a half thick, being mortised into the chep in an oblique direction, so that the point of the share will be two feet ten inches asunder from the beam. The chep is five feet in length, four inches in width, and five deep: to this is fixed the share, which weighs about 32lbs. and is manufactured of hammered iron, being one foot eight inches in length, and from four and a half to seven inches wide at the point. The upper end of the beam is supported on a carriage, furnished with two wheels, that are three feet two inches in height; on the axle-tree of which a galloway is placed, and provided with a sliding bolster, for the purpose of raising or lowering the machine. A clasp-iron likewise enters through the axle, to which a strong chain, or a tow passing over the beam, is fixed in such a manner, that the plough may, by means of notches, or a pin known under the name of a check, be let out to a greater length from the axle; and will consequently penetrate more deeply into the earth.

We have been induced to give this description of the Kentish plough, because it is an instrument of great strength, and eminently calculated for rocky and hilly countries, as it turns the soil to a considerable depth, laying it perfectly level, without making any furrow, or opening; a circumstance of equal advantage and importance, in dry situations.—The price of the whole, with its tackle complete for drawing, is computed to be about five guineas.

PLOUGH.

A valuable implement has very lately been introduced into the county of Lancaster, by Mr. Duckett, jun.—It is denominated a *trench-plough*, and is furnished with two shares, one being directly over the other, so that one narrow superficial furrow may be drawn from the surface of the soil, while another, at a moderate depth, is taken off beneath. This machine is well adapted for ploughing in green crops, or long dung, by way of manure; and, if the surface of the soil be foul, it may be turned under, and fresh soil brought up, from the depth of 10 inches, by employing three horses. The earth being thus loosened, the roots of plants are enabled to strike downwards without any impediment; and, while the land is drained, and exposed to the influence of the air, it is thereby considerably improved.

The *scalp-plough* or *extirpator*, as it is generally termed, was not long since invented by Mr. Hayward, of Stoke-Ash, in the county of Suffolk. Its beam is seven feet in length, and is furnished with two handles. The shares are eight inches broad, nine in length, and are fixed to stalks, about ten inches in height, and eleven inches asunder. Such implement may be adapted to the wheels of a common plough, and will penetrate the soil to a greater or less depth, in a similar manner. The object of this contrivance is, the eradication of weeds, and the clearing of ploughed lands for seed; in which respect it is said to be more serviceable than any other instrument. Before the extirpator is employed the soil ought to be once ploughed; and, if it have lain fallow during a summer, the scalp is passed over it, twice: namely, the first time about two inches deep, and the next, in a transverse direction, at the depth of about four inches. This operation, together with harrowing the ground once, will not only destroy all weeds, but will pulverize and prepare the soil for the reception of seed, whether drilled, or broad-cast. Farther, if lands, intended for the production of spring-crops, be ploughed in autumn, and the extirpator be afterwards passed over them, they will be rendered fit for immediate sowing.—This machine may be drawn either by two or by three horses, according to the nature of the soil, and the depth required: it possesses the peculiar advantage, that it may be worked on all arable lands, by any person capable of directing a plough, and that it will turn over an acre of ground in one hour, without fatiguing either horses or oxen.—Should the soil, however, be over-run with weeds, it will be advisable to plough it with the scalp, twice; and, in some cases, three times; a short space being allowed to intervene, with a view to deprive the weeds of their vegetating power.

Among the most valuable implements that have, within a few years, been constructed and adopted in this country, is the *Beverstone plough*, designed, or at least improved, by the ingenious Mr. Lewin Tugwell, of Beverstone, in the county of Gloucester. The diameter of the wheel is one foot, nine inches; the breadth at the heel, nine inches; breadth of the fin, seven inches; top of beam at the heel to the ground, eight inches and a half; the mould-board projects at the top more than the breadth at the heel, six inches; from the heel to the tuck-hole of the share, two feet, six inches and a half; and from the tuck-hole to the point of the share, eight inches and a half.

This excellent machine, which considerably varies from the Rotherham, and other valuable ploughs, gained the prize at the ploughing-match in 1798, held near Pipers-Inn, Somersetshire,

under the patronage of the Bath and West of England society. It may be easily worked by a pair of oxen, without a driver; and, on account of its simplicity, we believe that the representation, above given, will be sufficient to guide a skilful carpenter, in the construction of a similar implement.

The *double*, or *two-furrow swing* and *wheel-plough*, demands the attention of every enlightened agriculturist: we have therefore subjoined the following description, copied from the 21 vol. of Communications to the Board of Agriculture.

This machine, we understand, was originally invented by Mr. Duckett, but has lately been materially improved by the patriotic lord Somerville. The construction of the beam is nearly the same as that of the Beverstone plough; which his lordship (in his address to the board, in 1798) acknowledges himself to have adopted, from a consciousness of his inability to substitute any other better adapted to the purpose. The chief and most important improvement relates to the mould-board, one end of which was formerly cut off, and the deficiency supplied by driving in wedges, to the consequent injury of the mould-plate. As this expedient, however, was attended with much trouble, it was generally omitted; and consequently, the land imperfectly tilled. With a view to remedy such inconvenience, lord S. proposes (after the mould-board is formed, and the plate is fitted in the usual manner) to cut a part of it off, and to connect the part thus separated with the fixed part of the board by means either of flat hinges, or of thin, flexible plates of hard-hammered iron; so that those parts may be easily set to have different inclinations with such fixed part, by the aid of two screws that pass from the inside through the lower parts of the handle of the plough, opposite to the backs of the moveable pieces. The screws, he observes, may be so regulated as to keep such pieces at any degree of inclination that may be required, according to the nature of the land intended to be broken up.

The two-furrow plough is best adapted to light, and level soils, particularly for stirring ley-grounds; and, as these cannot be laid too flat or seed-earths be turned too much on an edge, the plough may be adapted to either purpose with the utmost facility, by this improvement of the mould-board. When the moveable parts, above alluded to, are screwed outwards, a proportionate convexity or elevation will be left at the base of the furrow; and thus more earth will be exposed for covering the seed. Lastly, his lordship directs that the part of the mould-plate most liable to wear off by repeated friction be made twice as thick as the other parts of the plate, viz. double "the thickness of a new crown-piece," or about one-fourth of an inch; in which case it will remain unimpaired nearly as long as the whole of the machinery.

Lord S. observes, that "the principle of this moveable plate may not at first catch the attention of every reader;" but it deserves to be generally adopted, and has indeed met with strong advocates in ploughmen: for it not only relieves their right arm of considerable labour, that must otherwise be performed in wedging and hammering mould-plates; but much exertion is also saved to the right leg, in attempting to tread those furrows flat, which had been left on an edge by the plough. Lastly, these plates are indispensably necessary, in order to qualify two-furrow ploughs for all broad work, and particularly brack-

PLOUGH.

ing up leys; and such implements ought (in the technical phrase) to work on their own base, close at heel; as otherwise the furrow will be irregularly laid, and they will be immediately "thrown out of work."

Before we conclude the account of this valuable contrivance, it is but justice to state the result of a trial made at Kew, in March 1799, on his majesty's farm, in consequence of a challenge given to Lord Somerville. The quantity of land, till then in a state of nature, amounted to 17½ statute acres, and was worked by this implement, four Devonshire oxen (six years old), and a man, with a boy as driver, in six days and four hours. The cattle were in good condition when they commenced the task; after the accomplishment of which, they appeared in better order than before. They were allowed no corn; consumed every day, upon an average, about 40lbs. of hay, during their continuance at Kew; and worked eight hours each day, including half an hour for bait.—The land, thus tilled, was viewed by many gentlemen, and able agriculturists, who highly approved of it, and were induced to order numbers of these ploughs; a conduct which, we trust, will at length be generally adopted.

The two-furrow plough has, indeed, been introduced into some of the midland counties, where it is employed with five horses and one man, in tolerably level soils, which it divides as effectually as two single ploughs.—It is also used, together with the single-wheel plough, in Staffordshire; as it requires only a lad to drive the horses, and to turn the plough at the end of the furrow.—For breaking up the turf, an iron flay is screwed to the coulter; by which the sward is cut off, and turned into the furrow, so as to be covered with earth. Thus, by the aid of an additional horse, the soil will resemble a fallow, and may be harrowed with equal facility.

One of the latest British ploughs, which merits particular notice, is that invented by Mr. J. Turner, jun. of Bockleton, Warwickshire; and of which the following description may convey some idea.

A strong piece of wood, denominated by the inventor a wing, projects in the middle; and in this one of the coulters is fixed. This piece of timber is fastened, at a proper distance from the ear or hook at the end of the beam, to the side of the beam, by means of long screws passing throughout the latter; with the opposite side of which they connect another wing, containing a second coulter.—These two coulters are placed in a parallel direction, and are both strengthened with a piece of iron, called the stay; one end of which is fixed about two inches beneath the wing, and the other is inserted in the wing itself.

The lower extremity of the plough is formed of a drock or piece of wood about six inches in width, three in depth, and rather more than two feet in length.—To the top of the drock is fastened an erect piece of timber known by the name of spindle, and behind are two tails.—To the upper end of the spindle is fixed the beam, the end of which is fastened between the tails, by means of an iron pin.

Connected with the drock and spindle are two shelfe-boards, which meet at an angular point. The ends of both these boards are strengthened by means of a short wooden stay, that is fixed in them, as well as in the tails.

A third coulter is fastened to the share, and

is bent at the end, in order that it may be more easily admitted through a hole in the beam, behind the other two coulters, when the share is put on the end of the drock.

The object of this contrivance is the formation of small drains or gutters in meadows, and pasture-land, with a view to carry off stagnant waters: which, by remaining on the surface, materially injure the soil.—To adjust the plough for work, a mark is first made in the middle of that end of the drock, which is contiguous to the tails; when a straight line is traced on a level spot of ground, on which such mark and the point of the share are put, and made to coincide. From this line the fore-coulters must be equi-distant.

The most effectual method of working this plough is, in the opinion of its inventor, to fasten a chain round the axle-tree of a pair of cart-wheels (the body of which has been taken off); to hook such chain to the ear at the end of the beam; and, by lengthening or shortening the chain, this machine may be so regulated as to penetrate the soil to a greater or less depth, according to the nature of the ground.—When the plough is at work, the fore-coulters cut the outside of the gutter.—The back coulter divides the ground exactly in the middle: the farther shelfe-board throws out half the soil on one side, while the near shelfe-board removes the other half to the opposite side; and thus a complete gutter is left, which extends from eight to ten inches in width, and is from six to eight inches deep.

One of the most important advantages resulting from this invention is the saving in manual labour, which is computed at three-fourths; as 400 perches of land may thus be drained in one day, by a team of five horses, two drivers, and a holder; the expence of which the inventor calculates at 16s.; whereas if the same quantity of land were to be dug by hand, the cost would amount to 31. 6s. 8d.

Mr. Turner's plough may be applied to another valuable branch of agriculture; namely, the planting of potatoes. His method is as follows: First, trenches are made with the machine, at the distance of about two feet from each other; and in which the potatoes are set. Some manure is next spread on them in such trenches, and they are covered by drawing the plough through the intermediate spaces; so that each trench is filled by a ridge of soil. When the growing potatoes require an additional covering of mould, the weeds are previously cut, either by a hoe or weeding-hook; and, the two fore-coulters being taken off the plough, the implement is drawn between the ridges; it throws up an additional portion of soil upon them; and thus expeditiously effects the operation of moulding.

Besides these, now described, several other ploughs have been contrived for particular purposes; these, however, with those enumerated in the article HUSBANDRY, are the chief: and we shall only add to the present article a description (extracted from M. Simonde's *Tableau de l'Agriculture Toscane*, 8vo. Geneva, 1801) of two ploughs that are used in Tuscany, as well as in other parts of Italy; and which, from the simplicity of their construction, deserve to be more generally known in Britain.

The first is denominated the *greater Tuscan plough*: the sock is an iron plate, somewhat concave, which is from eight to nine inches, both in breadth and in length; it is sharpened on every side, so as to divide the soil in an horizontal

direction, and with great ease. The coulter is perpendicular upon the angle of the sock; and a moveable board (*versoir*) is placed flat over the chep, in such a manner as to form a continuation of the sock, and to pass under the clod which the latter has raised: but, as it describes a curve on the side opposite to that of the coulter, it deviates from the line, and is turned upside-down, together with the soil which it has received. The implement, thus constructed, meets with the smallest possible resistance in working the ground; its sock divides the earth with a facility equal to that of a common spade; and, as its motion is continued, it acquires greater power of action than the latter:—the coulter also, being vertical, passes on with less difficulty than such as are always in an inclined position. Lastly, the Italian mould-board being flat, receives the soil from the sock, which it turns over to the side, without increasing the resistance encountered by the implement, in consequence of this secondary operation.

The *lesser Tuscan-plough* is lighter, and more diminutive in all its dimensions, than the preceding. Its sock is of a similar shape, but the coulter is perpendicular beneath its beam, between the course of the sock; and instead of the mould-board (of which this machine is destitute), its broad chep is formed in the shape of a plane (*doloire*) so as to turn the earth equally on both sides. In order to work the plough, the labourer conducts it between each border (*plate-bande*), which he divides at a single stroke, thrusting the soil of either side towards the furrow of the preceding year: and, while the latter is nearly filled up, he forms the trench, which is to continue open during the next season, so that the soil is alternately stirred, according to the system of Mr. Tuil; being sown one year, and serving as a furrow in the subsequent.—Thus the field presents alternately, after ploughing, two ridges adjoining to each other, and then a furrow. Next, the labourer passes a small square harrow over these elevations, which he levels; while the furrow remains untouched, and the soil is thus ultimately prepared for sowing.

The agricultural reader will observe, from the construction of these implements, that they are not calculated for working stiff clays; as the ground cannot be entirely removed, and some part must even remain untouched. But, in the rich friable soils of Tuscany, the smaller plough is a most useful instrument; for, in that country, the least effort is sufficient to divide and pulverize the land: we have been induced to communicate the kind above-mentioned, chiefly on account of its simplicity, and as there are similar soils in the southern parts of Britain; where, we conceive, the Italian ploughs may be advantageously employed.—Lastly, the deep furrows, that remain in the ground after it has been ploughed, present a greater surface to the action of the sun and air; a circumstance materially conducing to its improvement.

We have here given an extensive view of the subject, on account of its national importance.—Justice, however, impels us to mention another contrivance, for ascertaining the force necessary in the draught of various ploughs. It was presented to the public by Mr. More, the late ingenious secretary to the Society for the Encouragement of Arts, &c.: it consists of a spring coiled within a cylindrical case, which is furnished with a dial-plate numbered in a manner similar to that of a clock; and which is so constructed, that the hand

moves in consequence of the motion of the spring, and points to the numbers according to the force exerted: thus, if the draught be equal to one cwt. over a pulley, the hand will be directed towards figure 1; when the draught equals two cwt. it points to figure 2; and continues to increase, or diminish, its progress in proportion to the exertions made.

Various experiments were conducted under the inspection of the society, when the accuracy of this machine was fully evinced; a detailed account of which is inserted in the first volume of *Annals of Agriculture*, where the different results are minutely recorded.

PLOUGH, or PLOW, in navigation, an ancient mathematical instrument made of box or pear-tree, and used to take the height of the sun or stars in order to find the latitude.

It admits of the degrees to be very large, and has been much esteemed by many artists; though now generally disused amongst us.

PLOUGH, among bookbinders, is a machine for cutting smooth the edges of the leaves of books.

To PLOUGH. v. n. To practise aration; to turn up the ground to receive seed (*Isaiah*).

To PLOUGH. v. a. 1. To turn up with the plough (*Dryden*). **2.** To bring to view by the plough (*Woodward*). **3.** To furrow; to divide (*Addison*). **4.** To tear; to hollow (*Shakspeare*).

PLOUGHBOY. s. (*plough and boy*.) A boy that follows the plough; a coarse ignorant boy (*Watts*).

PLOUGHHER. s. (*from plough*.) One who ploughs or cultivates ground (*Spenser*).

PLOUGHING, in rural economy, denotes the stirring and turning over of land with the plough.

This is one of the most essential operations in the culture of the earth, and requires to be performed with the greatest care. Whatever, therefore, may be the design of the farmer, or the destination of the ground, thus moved, it ought never to be ploughed in a wet state; because the soil cannot be improved by such labour. Farther, the plough ought to be carried to a considerable depth into the soil; and, if one turning be not sufficient, it will be advisable to pass another plough over the same furrow, so that the land may be effectually stirred; when, being thus exposed to the air, its fertilizing properties will not only be considerably augmented, but all perennial weeds will be completely eradicated. Deep ploughing, however, is unnecessary for land that has been recently manured with lime or marl; but, on exhausted soils, it is uncommonly beneficial, and has, therefore, been generally recommended by the most skilful husbandmen.

Ploughing increases the food of plants; as it opens the soil for the reception of vegetable aliment from the air and light; and, the surface being consequently enlarged, a greater portion of land is thus exposed to its influence. Farther, by breaking up the ground, if it be too solid, and rendering it firm, in case it be too light, this operation greatly tends to improve the earth; and, as weeds and other

vegetable substances are thus reduced to a state of putrefaction, it promotes the nourishment of the new roots. Lastly, ploughing removes too great humidity, by forming the land into small ridges, and contributes to the eradication of weeds, as it first causes their seeds to vegetate, and afterwards tearing up the young plants, exposes their roots to the drought, in consequence of which they are deprived of their vegetative power. For the rest, see **PLOUGH** and **HUSBANDRY**.

PLOUGHLAND. *s.* (*plough and land*.)
A farm for corn (*Donne*).

PLOUGHMAN. *s.* (*plough and man*.)
1. One that attends or uses the plough; a cultivator of corn (*Taylor*). 2. A gross ignorant rustic (*Shakspeare*). 3. A strong laborious man (*Arbutnot*).

PLOUGHMAN'S OF PLOWMAN'S SPIKE-NARD. See **BACCHARIS** and **CONYZA**.

PLOUGHMONDAY. *s.* The Monday after Twelfth-day (*Tusser*).

PLOUGHSHARE. *s.* (*plough and share*.)
The part of the plough that is perpendicular to the coulter (*Sidney*).

PLOWDEN (Edmund), serjeant at law, was the son of Humphrey Plowden of Plowden in Shropshire, of an ancient and genteel family. He was first a student in the university of Cambridge, where he spent three years in the study of philosophy and medicine. He then removed to Oxford, where, having continued his former studies about four years more, in 1552 he was admitted to the practice of physic and surgery: but probably finding the practice of the art of healing less agreeable than the study, he entered himself of the Middle Temple, and began to read law. Wood says, that in 1557 he was summer reader to that society, and Lent-reader three years after, being then serjeant and oracle of the law. He died in the year 1584, aged 67; and was buried in the Temple-church near the north wall, at the east end of the choir. He married the daughter of William Sheldon of Boley, in Worcestershire; by whom he had a son, who died soon after his father. He wrote, 1. Commentaries or Reports of divers Cases, &c. in the Reigns of King Edward VI. Queen Mary, and Queen Elizabeth; London, 1571, 78, 99, 1613, &c. Written in the old Norman language. 2. Queries, or a Moot-book of Cases, &c. translated, methodized, and enlarged, by H. B. of Lincoln's Inn; Lond. 1662. 8vo.

PLUCHE (Antony), born at Rheims in 1688, merited by his engaging manners and proficiency in the belles-lettres the appointment of humanist in the university of that city. Two years after he obtained the professor of rhetoric's chair, and was admitted into holy orders. The bishop of Laon, (Clermont) informed of his talents, offered him the direction of the college of his episcopal city. By his industry and superior knowledge, a proper order and subordination soon took place in it; but some particular opinions respecting the affairs of the time disturbed his tranquillity, and obliged him to quit his office. The intendant

of Rouen, at the request of the celebrated Rollin, entrusted him with the education of his son. Abbé Pluche, having filled that place with success and great honour to himself, left Rouen and went to Paris, where, by the patronage of some literary friends and his own excellent writings, he acquired a very distinguished reputation for learning. He published, 1. *Le Spectacle de la Nature* (Nature Displayed), in 9 vols. in 12mo. This work, which is equally instructive and entertaining, is written with perspicuity and elegance; but the form of dialogue which the author adopted has drawn him into the fault of being too prolix. The speakers, who are the prior, the count, and countess, are not distinguished by any striking feature; but they have all the common character, which is tolerably pleasing, not excepting even that of the little chevalier De Breuil, who is, however, a mere scholar. This is the opinion which Abbé Desfontaines has formed of this work. Though the author has given the conversations a pretty ingenious turn, and even some vivacity, yet they now and then fall into the tone of the college. 2. *Histoire du Ciel, or History of the Heavens*, in 2 vols. in 12mo. In this performance we find two parts almost independent of one another. The first contains some learned inquiries into the origin of the poetic heavens. It is nearly a complete mythology, founded upon ideas which are new and ingenious. The second is the history of the opinions given by philosophers respecting the formation of the world. The author shows the inutility, inconstancy, and uncertainty, of the most esteemed systems; and concludes with pointing out the excellence and sublime simplicity of the Mosaic account. Besides a noble and well-turned expression, we find in it an erudition which does not fatigue the mind. As to the foundation of the system explained in the first part, though it appears plausible, we will not take upon us to say how far it is true: Voltaire called it *Fable du Ciel*, or a *Fable of the Heavens*. 3. *De Linguarum artificio*; a work which he translated with this title, *La Mécanique des Langues*, in 12mo. In this treatise he proposes a short and easy method of learning languages, which is by the use of translations instead of themes or exercises; and we must admit his reflections on that subject are both judicious and well expressed. 4. *Harmony of the Psalms and the Gospel, or a Translation of the Psalms and Hymns of the Church*, with Notes relative to the Vulgate, the Septuagint, and Hebrew Text, printed at Paris in 1764, in 12mo. In 1749, Abbé Pluche retired to Varenne St. Maure, where he gave himself up entirely to devotion and study. Having become so deaf that he could not hear without the help of a trumpet, the capital afforded him very little entertainment. It was in this retreat that he died of an apoplexy on the 20th of November 1761, at the age of 73 years. He possessed those qualities which form the scholar, the honest man, and the christian: temperate in his meals, true to his word, an affectionate

parent, a sensible friend, and a humane philosopher; he gave lessons of virtue in his life as well as in his writings. His submission to all the truths of religion was very unreserved. Some deists having been surprised that, in matters of faith, he should think and speak like the vulgar, his answer was, "I glory in doing so: it is infinitely more rational to believe the word of God, than to follow the glimmering lights of a reason which is limited and subject to error."

To PLUCK. *v. a.* (plocian, Saxon.) 1. To pull with nimbleness or force; to snatch; to pull; to draw; to force on or off; to force up or down (*Gay*). 2. To strip of feathers (*Sh.*). 3. To pluck up a heart or spirit. A proverbial expression for taking up or resuming of courage (*Knolles*).

PLUCK. *s.* (from the verb.) 1. A pull; a draw; a single act of plucking (*L'Estrange*). 2. The heart, liver, and lights of an animal.

PLUCKER. *s.* (from pluck.) One that plucks (*Shakespeare*).

PLUG. *s.* (*plugg*, Swedish; *plugghe*, Dut.) A stopple; any thing driven hard into another body to stop a hole (*Boyle*).

To PLUG. *v. n.* To stop with a plug (*Sharp*).

PLUKENETIA, in botany, a genus of the class monœcia, order monadelphica. Calyxless; corol four-petalled. Male: stamens eight; nectaries four, bearded. Fem.: style very long; stigma peltate, four-lobed; capsule four-grained. One species; a native of the Indies, with twining stem; heart-shaped, serrate, acute leaves; racemes of numerous male flowers and a few females at bottom.

PLUM. *s.* (plum, *plumtreop*, Saxon.) 1. A fruit with a stone (*Locke*). 2. Raisin; grape dried in the sun (*Shakespeare*). 3. (In the cant of the city.) The sum of one hundred thousand pounds (*Addison*). 4. A kind of play, called How many plums for a penny (*Ainsworth*).

PLUM, in botany. See PRUNUS.

PLUM (American black), in botany. See CHRYSOBALANUS.

PLUM (Bay), in botany. See PSIDIUM.

PLUM (Brazilian), in botany. See SPONDIAS.

PLUM (Indian date), in botany. See DIOSPYROS.

PLUM (Pishamin or Persimon), in botany. See DIOSPYROS.

PLUMAGE. *s.* (*plumage*, Fr.) Feathers; suit of feathers (*Bacon*).

PLUMB. *ad.* (from the noun.) Perpendicularly to the horizon (*Ray*).

To PLUMB. *v. a.* (from the noun.) 1. To sound; to search by a line with a weight at its end (*Swift*). 2. To regulate any work by the plummet.

PLUMB-LINE, among artificers, denotes a line perpendicular to the horizon: so called because it is commonly erected by means of a plummet.

PLUMBAGO. Leadwort. In botany, a genus of the class pentandria, order monogynia. Corol funnel-formed; stamens inserted into

scales closing the base of the corol; stigma five-cleft; seed one, oblong, coated. Seven species: south of Europe, Cape, India, America. The following are cultivated.

1. *P. Europæa*. European leadwort. Stiff, slender, channelled stem; leaves clasping the stem, lanceolate, rough; corol lead-colour. The leaves are used as a cure for the tooth-ach; whence it was formerly called in the dispensatories dentaria, or dentillaria. A native of the South of Europe.

2. *P. Zeylanica*. Ceylon leadwort. Leaves petioled, ovate, glabrous; upper part of the stalks and calyx of the flowers very glutinous, and sticky; entangling small flies that settle on them. India.

3. *P. rosea*. Rose leadwort. Leaves petioled, ovate, glabrous, slightly denticulate; stem with gibbous joints. A shrubby Indian plant.

4. *P. scandens*. Climbing leadwort. Leaves petioled, ovate, glabrous; stem flexuous, climbing; flowers terminal.

The first sort is increased by parting the roots; the other three should be raised from seeds sown in pots in the spring, and plunged into a hot-bed.

PLUMBAGO, carburet of iron. This mineral is found in various parts of Europe and America. It occurs in kidney-form lumps of various sizes. Its colour is dark iron-grey, or brownish-black; when cut, blueish-grey. Opaque and slaty; texture fine-grained; brittle; specific gravity from 1.98 to 2.09; feels somewhat greasy; stains the fingers, and marks strongly. The use of this mineral, when manufactured into pencils, is known to every person. It consists of

90 of carbon
10 of iron

100. See GRAPHITES.

PLUMBER. *s.* (*plombier*, Fr.) One who works upon lead.

PLUMBERY, the art of casting and working lead, and using it in building. As this metal melts soon and with little heat, it is easy to cast it into figures of any kind, by running it into moulds of brass, clay, plaster, &c. But the chief article in plumbery is sheets and pipes of lead; and as these make the basis of the plumber's work, we shall here give the process of making them.

In casting sheet-lead, a table or mould is made use of, which consists of large pieces of wood well jointed, and bound with bars of iron at the ends, on the sides of which runs a frame, consisting of a ledge, or border of wood, two or three inches thick, and two or three inches high from the mould, called the sharps: the ordinary width of the mould, within these sharps, is from three to four feet; and its length is sixteen, seventeen, or eighteen feet. This should be something longer than the sheets are intended to be, in order that the end where the metal runs off from the mould may be cut off, because it is commonly thin, or uneven, or ragged at the end. It must stand very even or level in breadth, and something

PLUMBERY.

falling from the end in which the metal is poured in, viz. about an inch, or an inch and a half, in the length of sixteen or seventeen inches. At the upper end of the mould stands the pan, which is a concave triangular prism, composed of two planks nailed together at right angles, and two triangular pieces fitted in between them at the ends. The length of this pan is the whole breadth of the mould in which the sheets are cast; it stands with its bottom, which is a sharp edge, on a form at the end of the mould, leaning with one side against it, and on the opposite side is a handle to lift it up by, to pour out the melted lead; and on that side of the pan next the mould are two iron hooks to take hold of the mould, and prevent the pan from slipping, while the melted lead is pouring out of it into the mould. This pan is lined on the inside with moistened sand, to prevent it from being fired by the hot metal. The mould is also spread over, about two-thirds of an inch thick, with sand sifted and moistened, which is rendered perfectly level by moving over it a piece of wood called a strike, by trampling upon it with the feet, and smoothing it over with a smoothing plane, which is a thick plate of polished brass, about nine inches square, turned up on all the four edges, and with a handle fitted on the upper or concave side. The sand being thus smoothed, it is fit for casting sheets of lead; but if they would cast a cistern, they measure out the bigness of the four sides, and having taken the dimensions of the front, or fore-part, make mouldings by pressing long slips of wood, which contain the same mouldings, into the level sand, and form the figures of birds, beasts, &c. by pressing in the same manner leaden figures upon it, and then taking them off, and at the same time smoothing the surface where any of the sand is raised up, by making these impressions upon it.

The rest of the operation is the same in casting either cisterns or plain sheets of lead; but before we proceed to mention the manner in which that is performed, it will be necessary to give a more particular description of the strike. The strike, then, is a piece of board about five inches broad, and something longer than the breadth of the mould on the inside; and at each end is cut a notch about two inches deep, so that when it is used, it rides upon the sharps with those notches. Before they begin to cast, the strike is made ready by tacking on two pieces of an old hat on the notches, or by slipping a case of leather over each end, in order to raise the under side about one eighth of an inch, or something more, above the sand, according as they would have the sheet to be in thickness; then they tallow the under edge of the strike, and lay it across the mould. The lead being melted, it is ladled into the pan, in which, when there is a sufficient quantity for the present purpose, the scum of the metal is swept off with a piece of board to the edge of the pan, letting it settle on the sand, which is by this means prevented from falling into the mould at the pouring out of the metal. When

the lead is cool enough, which is known by its beginning to stand with a shell or wall on the sand round the pan, two men take the pan by the handle, or else one of them lifts it up by a bar and chain fixed to a beam in the ceiling, and pour it into the mould, while another man stands ready with the strike, and, as soon as they have done pouring in the metal, puts on the mould, sweeps the lead forward, and draws the overplus into a trough prepared to receive it. The sheets being thus cast, nothing remains but to planish the edges, in order to render them smooth and straight; but if it be a cistern, it is bent into four sides, so that the two ends may join the back, where they are soldered together, after which the bottom is soldered up.

The method of casting thin sheets of lead.—Instead of sand, they cover the mould with a piece of woollen stuff nailed down at the two ends to keep it tight, and over this lay a very fine linen cloth. In this process great regard is had to the just degree of heat, so as that the lead may run well, and yet not burn the linen. This they judge of by a piece of paper, for it takes fire in the liquid lead if it is too hot, and if it be not shrunk and scorched a little, it is not hot enough.

The method of casting pipes without soldering.—To make these pipes they have a kind of little mill, with arms or levers to turn it withal. The moulds are of brass, and consist of two pieces, which open and shut by means of hooks and hinges, their inward calibre, or diameter, being according to the size of the pipe to be made, and their length is usually two feet and a half. In the middle is placed a core, or round piece of brass or iron, somewhat longer than the mould, and of the thickness of the inward diameter of the pipe. This core is passed through two copper rundles, one at each end of the mould, which they serve to close; and to these is joined a little copper tube, about two inches long, and of the thickness the leaden pipe is intended to be of. By means of these tubes the core is retained in the middle of the cavity of the mould. The core being in the mould, with the rundles at its two ends, and the lead melted in the furnace, they take it up in a ladle, and pour it into the mould by a little aperture at one end, made in the form of a funnel. When the mould is full, they pass a hook into the end of the core, and, turning the mill, draw it out; and then, opening the mould, take out the pipe. If they desire to have the pipe lengthened, they put one end of it in the lower end of the mould, and pass the end of the core into it; then shut the mould again, and apply its rundle and tube as before, the pipe just cast serving for rundle, &c. at the other end. Things being thus replaced, they pour in fresh metal, and repeat the operation till they have got a pipe of the length required. For making pipes of sheet-lead, the plumbers have wooden cylinders, of the length and thickness required, and on these they form their pipes by wrapping the sheet around them, and soldering up the edges all along them.

PLUMBUM.

PLUMBUM. Lead. In mineralogy, a genus of the class metals. Blueish-white, gradually blackening in the air, soft, very malleable, a little ductile and tenacious, not sonorous, staining the fingers of a blueish colour, specific gravity 11,352, easily melting, exhibiting iridescent colours on the surface during liquefaction, and becoming first a white, then a grey, then a yellow, and lastly a red oxyd, all of which are easily convertible into glass; soluble in all acids, and giving the solution a sweetish taste, precipitating a yellow powder if dissolved in nitric acid, and potash be added to the solution. Twenty-three species.

1. *P. nativum.* Native, or naked lead. Found in Monmouthshire, Poland, and Silesia; though it is much doubted whether lead be ever found in a perfectly metallic state.

2. *P. ochraceum.* Earthy lead-ore: earthy lead ochre: white opake lead-ore. Pulverulent, without lustre, totally soluble in nitric acid with effervescence, easily reducible to a metallic state on charcoal. Found in various lead mines of Great Britain, Saxony, Germany, &c. in a loose earthy state, and generally seated on galena: colour white, grey, red, or yellow; becomes red when exposed to a sufficient heat, and contains a considerable portion of carbonic acid gas: yields from 60 to 80 per cent. of lead.

3. *P. terreum.* Earthy lead-ore; white opake lead-ore; earthy indurated lead-ore. Indurated, without lustre, earthy internally, soluble in nitric acid with effervescence. Found with the last, of which it is perhaps only an indurated variety, in larger or less masses intermixed with masses of other ores and fossils, in various shades of white, grey, blue, yellow, red or brown.

4. *P. micaceum.* Greasy to the touch, lamellar, of a silvery colour and lustre. Found in the mines of the Hartz, and consists of numerous plates incumbent on each other.

5. *P. vitreum.* Glass of lead. Semitransparent, brittle, of a glassy texture and lustre and common form. Found in Somersetshire, and the lead-hills in Scotland, in France, Saxony, Siberia, Hungary, &c.; colour white, grey, or yellowish-green; texture conchoidal or splintery; it does not effervesce with nitric acid.

6. *P. spatiosum.* Carbonat of lead: white lead-ore: white carbonat of lead. Shining externally and internally, soft, white, decrepitating in the fire, effervescing with acids generally in the form of crystals. Found in various parts of Great Britain and Ireland, in Burgundy, Austria, Saxony, Hungary, rarely in a globular or cellular form, or disseminated, but most commonly crystallized in rectangular eight-sided prisms with obtuse pyramids variously truncated, or in tables or various forms; colour silvery or pale white, with sometimes a silky lustre, or tinged with brown, greenish, or yellowish; texture lamellar or conchoidal, of the crystals often fibrous; soft enough to be cut with a knife, and soluble in fat oils; when heated decrepitates, then turns yellow, and

afterwards red; before the blowpipe is quickly reduced, and blackens with sulphurated volatile alkali; specific gravity from 6,250 to 6,920: contains

Oxyd of lead	-	-	-	84
Carbonic acid	-	-	-	16

100 *Klaproth.*

7. *P. hyalinum.* Murio-carbonat of lead. Transparent, effervescing with nitric acid, soft, decrepitating on red hot coals, of a glassy lustre, in the form of crystals. Found in the mines of Derbyshire and of the Hartz, in crystals; colour from a clear transparent white to a pale straw-yellow, with a lustre much exceeding that of the last; texture glassy, resembling that of precious stones; soft enough to be scratched by carbonat of lead; specific gravity 6,065: consists of

Oxyd of lead	-	-	-	85
Carbonic acid	-	-	-	6
Muriatic acid	-	-	-	8
Loss	-	-	-	1

100

8. *P. flavum.* Yellow lead-ore: molybdat of lead: yellow molybdenated lead-ore. Yellow, in the form of crystals, soft, decrepitating before the blowpipe, soluble in muriatic and sulphuric acids, and giving a blue colour to hot sulphuric acid. Found at the lead-hills in Scotland, in Carinthia, Britany, Burgundy, the Hartz, Austria, &c. seldom massive, disseminated, or lamellar, but most commonly crystallized; colour various shades of yellow with a waxy lustre and generally somewhat transparent, with a white streak; fracture conchoidal; before the blowpipe it decrepitates and melts into a yellowish and blackish-grey mass, producing globules of lead: specific gravity 5,486.

9. *P. virens.* Phosphat of lead: phosphorated lead-ore. Greenish, ponderous, breaking into indeterminate fragments and reducible to a yellow powder, nearly soluble in hot nitric acid without effervescence, melting before the blowpipe, and crystallizing on cooling. Found in the lead-mines of Great Britain, New Spain, Siberia, Bohemia, Germany, Carinthia, massive, disseminated, imitative, in six-sided columns variously modified; colour various shades of green, with often a mixture of yellowish or greyish, or yellowish-brown, shining, transparent, with a greenish-white streak and yellowish powder; before the blowpipe it melts easily, and crystallizes on cooling; texture foliated, fracture inclining to conchoidal: specific gravity from 6,270 to 6,560.

10. *P. jaspideum.* Brown, hard, opake, of a common form. Found near Saska on the Carpathic mountains, and contains 36 per cent. of lead and a little silver and gold.

11. *P. fuliginosum.* Black, without lustre, soiling the fingers, not totally soluble in nitric acid, emitting sulphurous flames and vapours before the blowpipe, and crystallizing on cooling. Found at Freyburg, and in Britany; and besides oxyd of lead and phosphoric acid,

contains some sulphur; perhaps only a sulphurat of lead in a decomposing state.

12. *P. alvernium*. Arsenico-phosphat of lead; arsenicated phosphat of lead. Greenish-yellow, without lustre, bubbling and emitting arsenical fumes before the blowpipe, and crystallizing on cooling. Found at Auvergne in France, in masses, or crystallized in small six-sided prisms; colour yellowish-green, of various shades; fracture fibrous, striated, or conchoidal; before the blowpipe melts easily with effervescence, emitting a white smoke and arsenical smell: specific gravity 6,846.

13. *P. arsenicatum*. Arseniat of lead; arsenicated lead-ore. Without lustre, melting before the blowpipe, but not crystallizing on cooling; emitting arsenical fumes when heated to whiteness, and leaving a bead of lead. Found in the mines of Burgundy and Andalusia, in quartz or feldspar, and in small masses; colour pale-green or yellowish-green with a waxy lustre; when thrown on hot coals it easily becomes white.

14. *P. duplex*. Without lustre; before the blowpipe emitting arsenical and sulphuric flames and vapours. Found at Auvergne in France, and consists of oxyd of lead combined with the arsenical and sulphuric acids.

15. *P. vitriolatum*. Sulphat of lead; vitriol of lead; vitriolated lead. Whitish, without lustre, quite fixed, easily melting before the blowpipe without decrepitation or effervescence, not effervescing with acids. Found in the lead-mines of Strontian in Scotland, in Anglesea and Andalusia, sometimes variously modified, but generally in very minute crystals, but mostly above the beds of galena, from the decomposition of which it seems to originate; colour white or grey, more or less pellucid; fracture compact; partly soluble in water, and soon reduced before the blowpipe; specific gravity 6,300.

16. *P. corneum*. White, without metallic lustre, easily melting before the blowpipe, and in a greater heat entirely evaporating. Found in the mines of Lotharingia and Bohemia.

17. *P. plumbago*. Compact galena. With metallic lustre, easily melting with sulphurous vapour and flame, and leaving a bead of lead without any mixture of silver. Found in the lead-mines of England and Scotland, and Norway, Sweden, Spain, Saxony, &c. in masses, nodular or specular; colour lead-grey with a bright streak; texture compact, generally breaking into indeterminate fragments: specific gravity 7,444; contains merely lead combined with sulphur.

18. *P. galena*. Galena; lead-glance; sulphur of lead; sulphuret of lead. Of the colour and lustre of lead, ponderous, soft, presenting granular concretions, breaking into cubical fragments, melting with a sulphurous flame and vapours, and when the lead is reduced to a glassy oxyd, leaving a bead of silver.

Another species of an indigo-blue and lead-grey, compact, foliated, or fibrous, sometimes

striate longitudinally, known by the name of blue lead-ore.

Found in various parts of Great Britain and the continent, particularly Siberia, massive, in nodules, investing or specular, and often coated with gold or silver mica; texture foliated with cubical fragments; brittle; sometimes soft enough to be cut with a knife, and often stains the fingers; before the blowpipe decrepitates, melts easily with a sulphurous smell, and if alternately heated and cooled will at last vanish, leaving its silver behind; it is composed of various modifications of lead, sulphur, and silver: specific gravity from 7,220 to 7,587.

19. *P. feriferum*. Brown lead-ore; basaltic lead; striated galena. With metallic lustre, melting with sulphurous vapours and flame, but more difficultly than galena, and if the heat be increased forming a black glass. Found in the mines of Sweden, sometimes massive, sometimes crystallized in clusters, containing besides lead and sulphur, some silver and iron.

20. *P. stibiatum*. Antimonial lead-ore. Of the colour and lustre of lead, fibrous, breaking into crustose fragments. Found in the mines of Siberia, Sweden, Hungary, and Spain, of a compact and striated texture, with the pieces into which it breaks either straight or incurved, and the fibres parallel or fascicled; when heated it emits sulphurous flame and vapours; besides lead and sulphur, it contains antimony and silver.

21. *P. hereynicum*. Weisgolden. Klaproth. Combined with copper and antimony, a smaller proportion of iron and sulphur, and a very small quantity of silver, with metallic lustre. Found in the mines of Andreasburg in the Harz; contains

Lead	-	-	-	34,0
Copper	-	-	-	16,3
Antimony	-	-	-	16,0
Iron	-	-	-	13,7
Sulphur	-	-	-	10,0
Silver	-	-	-	2,3
Loss	-	-	-	7,7

100 Klaproth.

22. *P. cornubicum*. Combined with antimony and a smaller proportion of copper and sulphur, and a very small quantity of iron, with metallic lustre. Found in the mines of Cornwall, and contains

Oxyd of lead	-	-	-	50
Antimony	-	-	-	21
Copper	-	-	-	14
Sulphur	-	-	-	7
Iron	-	-	-	2
Loss	-	-	-	6

100 Klaproth.

23. *P. subaudiicum*. With metallic lustre, emitting arsenical vapours before the blowpipe. Found in the mines of Subandia, and consists of oxyd of lead, antimony and arsenic.

PLUMCAKE. *s.* (*plum* and *cake*) Cake made with raisins (*Hudibras*).

PLUME. *s.* (*plume*, French; *pluma*, Lat.)

H H

1. Feather of birds (*Milton*). 2. Feather worn as an ornament (*Dryden*). 3. Pride; towering mien (*Shakspeare*). 4. Token of honour; prize of contest (*Milton*). 5. That part of the seed of a plant, which in its growth becomes the trunk (*Quincy*).

TO PLUME. *v. a.* (from the noun.) 1. To pick and adjust feathers (*Mort.*). 2. (*plumer*, Fr.) To strip off feathers (*Ray*). 3. To strip; to pill (*Bacon*). 4. To place as a plume (*Milton*). 5. To adorn with plumes (*Shakspeare*). 6. To make proud: 'as, he plumes himself.

PLUMERIA, in botany, a genus of the class pentandria, order monogynia. Corol twisted; follicles two, reflected; seeds two, inserted into their proper membrane. Four species, natives of the West Indies or America.

1. *P. rubra*. Red plumeria, or jasmine. A milky succulent shrub, with clustered, terminal flowers of a pale red colour.

2. *P. alba*. Whiteplumeria. Flowers white, in spikes with a yellowish eye, and considerable fragrance.

3. *P. obtusa*. Blunt-leaved plumeria. Flowers like the last on branched peduncles.

4. *P. pudica*. Close-flowered plumeria. Flowers numerous, yellowish, rolled up like those of hibiscus; odour exquisite.

All are cultivated, and may be increased by seeds or cuttings; but require, excepting in the warmer months, the aid of a greenhouse.

PLUM'GEROUS. *a.* (*pluma* and *gero*, Lat.) Having feathers; feathered.

PLUM'PEDE. *s.* (*pluma* and *pes*, Latin.) A fowl that has feathers on the foot.

PLUMMET, **PLUMB-RULE**, or **PLUMB-LINE**, an instrument used by carpenters, masons, &c. in order to judge whether walls, &c. be upright planes, horizontal, or the like. It is thus called from a piece of lead, *plumbum*, fastened to the end of a cord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, &c. raised perpendicularly on another; in which case it becomes a level. See **LEVEL**.

PLUMMING, among miners, is the method of using a mine-dial, in order to know the exact place of the work where to sink down an air-shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it. It is performed in this manner: a skilful person, with an assistant, and with pen, ink, and paper, and a long line, and a sun-dial, after his guess of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it, then the incited needle is let to rest, and the exact point where it rests is marked with a pen: he then goes on further in the line still fastened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwise; and then letting down the dial again, he there likewise notes down that point at which the needle stands in this second position. In this manner he proceeds from turning to turning, marked down the points, and marking the line, till he

comes to the intended place; this done, he ascends and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing, and continues this till he comes to the desired place above ground, which is certain to be perpendicularly over the part of the mine into which the air-shaft is to be sunk.

PLUMOSE or **PLUMOUS BRISTLE.** In botany. A feathered bristle. *Villosa composita*. Having hairs growing on the sides of the main bristle. Resembling a feather.

PLUMOSE PAPPUS. Feathered or compound down. *Pilis pennatis constans*—*s. villosus compositus*. A flying crown to some seeds, composed of compound or feathery hairs: as in *crepis*, *scorzonera*, *tragopogon*. Opposed to capillary. See **PAPPUS**.

PLUMOSITY. *s.* (from *plumous*.) The state of having feathers.

PLUMOUS. *a.* (*plumeux*, Fr. *plumosus*, Lat.) Feathery; resembling feathers (*Woodward*).

PLUMP. *a.* (perhaps from *plum*, when full and ripe.) Somewhat fat; not lean; sleek; full and smooth (*L'Estrange*).

PLUMP. *s.* (from the adjective.) A knot; a tuft; a cluster; a number joined in one mass. Now corrupted to *clump* (*Sandys*).

TO PLUMP. *v. a.* (from the adjective.) To fatten; to swell; to make large (*Boyle*).

TO PLUMP. *v. n.* (from the adverb.) 1. To fall like a stone in the water. 2. (from the adjective.) To be swollen.

PLUMP. *ad.* (probably corrupted from *plumb*, or perhaps from the sound of a stone falling on the water.) With a sudden fall (*Ben Jonson*).

PLUM'PER. *s.* Something worn in the mouth to swell out the cheeks (*Swift*).

PLUM'PNES. *s.* Fulness; disposition toward fatness (*Newton*).

PLUM'PORRIDGE. *s.* (*plum* and *porridge*.) Porridge with plums (*Addison*).

PLUM'PUDDING. *s.* (*plum* and *pudding*.) Pudding made with plums.

PLUM'PY. *a.* Plump; fat (*Shakspeare*).

PLUMULE. The plume, or ascending scaly part of the coraculum or heartlet of the seed.

PLUM'Y. *a.* (from *plume*.) Feathered; covered with feathers (*Milton*).

TO PLUN'DER. *v. a.* (*plunderin*, Dutch.) 1. To pillage; to rob in an hostile way (*South*).

2. To take by pillage (*Dryden*). 3. To rob as a thief (*Pope*).

PLUN'DER. *s.* (from the verb.) Pillage; spoils gotten in war (*Otway*).

PLUN'DERER. *s.* (from *plunder*.) 1. Hostile pillager; spoiler. 2. A thief; a robber.

TO PLUNGE. *v. a.* (*plonger*, Fr.) 1. To put suddenly under water, or under any thing supposed liquid (*Dryden*). 2. To put into any state suddenly (*Dryden*). 3. To hurry into any distress (*Watts*). 4. To force in suddenly.

To PLUNGE. v. n. 1. To sink suddenly into water; to dive (*Shakspeare*). 2. To fall or rush into any hazard or distress (*Tillotson*).

PLUNGE. s. 1. Act of putting or sinking under water. 2. Difficulty; strait; distress (*Baker*).

PLUNGEON. s. (*mergus*, Lat.) A sea bird (*Ainsworth*).

PLUNGER. s. (from *plunge*.) One that plunges; a diver.

PLUNGER, in mechanics, a solid brass cylinder, used as a forcer in forcing pumps.

PLU'NKET. s. A kind of blue colour (*Ainsworth*).

PLU'RAL. a. (*pluralis*, Latin.) Implying more than one (*Shakspeare*).

PLURALIST. s. (*pluraliste*, French.) One that holds more ecclesiastical benefices than one, with cure of souls (*Collier*).

PLURA'LITY. s. (*pluralité*, French.) 1. The state of being or having a greater number (*Bacon*). 2. A number more than one (*Hammond*). 3. More cures of souls than one. 4. The greater number; the majority (*L'Es-trange*).

PLURALLY. ad. (from *plural*.) In a sense implying more than one.

PLUS, in algebra, the affirmative or positive sign, +, signifying more or addition, or that the quantity following it is either to be considered as a positive or affirmative quantity, or that it is to be added to the other quantities; so $4 + 6 = 10$, is read thus, 4 plus 6 is equal to 10. See **AFFIRMATIVE SIGN**.

The more early writers of algebra, as Lucas de Burgo, Cardan, Tartaglia, &c. wrote the word mostly at full length. Afterwards the word was contracted or abbreviated, using one or two of its first letters; which initial was, by the Germans we think, corrupted to the present character +; which was first used by Stifelius, printed in his *Arithmetic*.

PLUSH, in commerce, &c. a kind of stuff leaving a sort of velvet knap, or shag, on one side, composed regularly of a woof of a single woollen thread, and a double warp, the one wool, of two threads twisted, the other goats or camel's hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

Plush is manufactured, like velvet, on a loom with three treadles; two of these separate and depress the woollen warp, and the third raises the hair warp, upon which the workman throwing the shuttle passes the woof between the woollen and hair warp; and afterwards laying a brass broach, or needle, under that of the hair, he cuts it with a knife destined for that use; conducting the knife on the broach, which is made a little hollow all its length, and thus gives the surface of the plush an appearance of velvet. See **VELVET**.

There are other kinds of plush, all of silk; some of which have a pretty long knap on one side, and some on both.

PLUTARCH, a native of Chæronea, descended of a respectable family. Under Ammonius, a reputable teacher at Delphi, Plutarch

was made acquainted with philosophy and mathematics. He afterwards travelled in quest of knowledge, and after he had visited the territories of Egypt and Greece, he retired to Rome, where he opened a school, which was much frequented. The emperor Trajan admired his abilities, honoured him with the office of consul, and appointed him governor of Illyricum. After the death of his imperial benefactor, Plutarch removed to Chæronea. In this peaceful and solitary retreat, Plutarch closely applied himself to study, and wrote the greatest part of his works, and particularly his *Lives*. He died in an advanced old age at Chæronea, about the 140th year of the Christian era. In his private and public character he was the friend of discipline, and boldly asserted the natural right of mankind, liberty.

Plutarch's works admit of a nearly equal division, into *Lives* and *Morals*; the former of which, in his own estimation, were to be preferred as more noble than the latter. His style has been excepted to with some reason: he has also been criticised for some mistakes in Roman antiquities, and for a little partiality to the Greeks. On the other hand, he has been justly praised for the copiousness of his fine sense and learning, for his integrity, and for a certain air of goodness which appears in all he wrote. His business was not to please the ear, but to instruct and charm the mind; and in this none ever went beyond him. Of his moral writings it is to be regretted that we have no elegant English translation. Even his *Lives* were chiefly known to the English reader by a motley and miserable version, till a new one, executed with fidelity and spirit, was presented to the public by the Langhorns in 1770; and this has been recently much improved by Mr. Wrangham. On the whole, it is to be wished that this most amiable moralist and biographer had added a life of himself to those which he has given to the world of others, as the particulars which other writers have preserved of his personal history are very doubtful and imperfect.

Of the Works of Plutarch, the best editions with which we are acquainted are that of H. Stephens, in 13 vols. 8vo. published in 1572, and the elaborate edition of Reiske, in 12 vols. 8vo. published at Leipsic in 1774. Of the *Lives*, the best edition is that of Bryan, published at London in 1729, 5 vols. 4to: of the *Morals*, we have the highly celebrated edition of Wyttenbach, published at Oxford in 1795, both in 4to. and 8vo: the 4to. copies are greatly to be preferred.

PLUTO, in pagan worship, son of Saturn and Ops, inherited his father's kingdom with his brothers Jupiter and Neptune. He received as his lot the kingdom of hell, and whatever lies under the earth, and therefore he became the god of the infernal regions. From his functions, and the place he inhabited, he received different names. He was called Dis, Hades, or Ades, Orcus, &c. As his residence was gloomy, all the goddesses refused to marry him; but upon seeing Proserpine, the daugh-

ter of Ceres, gathering flowers in the plains of Enna, in Sicily, he became enamoured of her, and immediately carried her away. Proserpine called upon her attendants for help, but in vain; and she became the wife of her ravisher, and the queen of hell. Pluto is looked upon as a hard-hearted and inexorable god, with a grim and dismal countenance, and for that reason no temples were raised to his honour, as to the rest of the superior gods. Black victims, and particularly a bull, were the only sacrifices offered to him. Among plants, the cypress, the narcissus, and the maiden-hair, were sacred to him, as also the number two. The dog Cerberus watched at his feet, the harpies hovered around him, and Proserpine sat on his left hand. The Paræ occupied the right. Pluto is called by some the father of the Euménides.

PLUTUS, in pagan worship, son of Jasion or Jasius, by Ceres, the goddess of corn, was the god of riches. He was brought up by the goddess of peace, and on that account, Pax was represented at Athens as holding the god of wealth in her lap. He was represented as blind, because he distributed riches indiscriminately; he was lame, because he came slow and gradually; and he had wings, to intimate that he flew away with more velocity than he approached mankind.

PLUVIAL. **PLUVIOUS**, *a.* (from *pluvia*, Latin.) Rainy; relating to rain (*Brown*).

PLUVIAL. *s.* (*pluvial*, French.) A priest's cope (*Ainsworth*).

PLUVIALES. See **CHARADRIUS**.

PLUVIAMETER. (from *pluvia*, rain; *metior*, to measure.) A machine or apparatus by which the quantity of rain that falls in any given place is measured. This is sometimes called ambrometer, and at others rain-gauge.

The pluviometer employed at the house of the Royal Society is described by Mr. Cavendish in the Philosophical Transactions for 1776. The vessel which receives the rain is a conical funnel, strengthened at the top by a brass ring, 12 inches in diameter. The sides of the funnel and inner lip of the brass ring are inclined to the horizon, in an angle of above 65°; and the outer lip in an angle of above 50°; which are such degrees of steepness, that there seems no probability either that any rain which falls within the funnel, or on the inner lip of the ring, shall dash out, or that any which falls on the outer lip shall dash into the funnel. Figure 3. pl. 139. is a vertical section of the funnel, ABC and *abc* being the brass ring, BA and *ba* the inner lip, and BC and *bc* the outer.

The rain-gauge used by Mr. Luke Howard, of Plaistow, is in some respects of a peculiar construction. It consists of three parts—the funnel, the reservoir, and the scale. The funnel is 8 inches in diameter, and its cylindrical rim is an inch deep: it terminates in a pipe leading into a conical vessel, having five or six times the capacity of the funnel, and closed at its apex, which is downward, with a stop-cock. The latter enters into a glass tube, full an inch

wide, graduated from the bottom (where is placed another cock) in divisions, each corresponding to one hundredth of an inch in the cylinder of the funnel, which is not contracted above. The rain, entering by the funnel, is received in the cone, where, in case of sudden frost ensuing, it cannot injure the instrument by expansion, and where it may also be suffered to accumulate for a month, if required, with little loss by evaporation (if the conducting pipe is pretty long and narrow) and be measured off at any time. By this construction also the funnel may be placed on the roof or parapet of a house, while the reservoir and gauge may be within and more easily accessible. Both the gauges are about 30 feet from the ground. In fixing pluviometers care should be taken that the rain may have free access to them, without being impeded or overshadowed by buildings, &c.; and therefore the tops of houses are mostly to be preferred. Also when the quantities of rain collected in them, at different places, are compared together, the instruments ought to be fixed at the same height above the ground at both places; because at different heights the quantities are always different, even in the same place. And hence also, any register or account of rain in the pluviometer ought to be accompanied with a note of the height above the ground the instrument is placed at.

PLUVIERS, or **PITHIVIERS**, a town of France, in the department of Eure and Loire, 20 miles N. of Orleans. Lon. 2. 0 E. Lat. 48. 14 N.

PLUVIUS, a surname of Jupiter, invoked among the Romans, whenever the earth was parched up by continual heat. He had an altar in the temple on the capitol.

To PLY. *v. a.* (*plien*, to work at any thing, old Dutch.) 1. To work on any thing closely and importunately (*Dryden*). 2. To employ with diligence; to keep busy; to set on work (*Hudibras*). 3. To practise diligently (*Milton*). 4. To solicit importunately (*Sou.*).

To PLY. *v. n.* 1. To work, or offer service (*Spectator*). 2. To go in haste (*Milton*). 3. To busy one's self (*Dryden*). 4. (*plier*, French.) To bend (*L'Estrange*).

PLY. *s.* (from the verb.) 1. Bent; turn; form; cast; bias (*Bacon*). 2. Plait; fold (*Arbutnot*).

PLYERS. *s.* See **PLIERS**.

PLYM, a river of England, in the county of Devon, which becomes navigable at Plymouth, and falls into Plymouth Sound, a little below Plymouth.

PLYMOUTH, a seaport town of England, in the county of Devon, situated on the English Channel, at the conflux of the two rivers, Tamer and Plym, which form a harbour, capable of receiving a thousand vessels. Plymouth is defended by several forts, and a citadel. The inlet of the mouth of the Tamer is called Hamoaze, and the mouth of the Plym, Catwater. Up the Hamoaze are docks for the building of vessels, with large magazines and store-houses. Here are spacious and com-

modious barracks for soldiers; with houses for the officers, clerks, &c. with arms, stores, and all things necessary to equip a fleet; this is called Plymouth Dock, or Dock only. In the reign of Edward III. part of this town was burned by the French; and in the reign of Henry IV. 600 houses were burnt by the same enemy. During the civil wars of the last century, Plymouth adhered to the Parliament, and stood a siege of the royal army for some months. At the restoration, Charles II. built a fort between the sea and the town, which kept the inhabitants in awe, and defends the harbour. The inhabitants carry on the pilchard fishery, and a considerable trade to the Straits of Newfoundland. Plymouth contains two parish churches, and in 1801 the number of inhabitants was 19,040. It is governed by a mayor, aldermen, &c. and sends two members to the British parliament. Here are three markets weekly, viz. on Monday, Thursday, and Saturday. It is 43 miles S.W. of Exeter, and 216 W. by S. of London. Lon. 4. 7 W. Lat. 50. 21 N.

PLYMOUTH, a seaport town of United America, in the state of Massachusetts, on the west side of Cape Cod; fifteen miles S.E. Boston. Lon. 70. 40 W. Greenwich. Lat. 41. 57 N.

PLYMOUTH, a town of New Hampshire, in Grafton county, situate on the Pemigewasset, at the mouth of Baker river, 45 miles N. of Concord.

PLYMOUTH, a town of N. Carolina, on the S. side of Roanoke river, four miles above Albemarle sound, and 23 S.S.W. of Edenton.

PLYMOUTH-DOCK, the largest town in Devonshire, situate two miles N.W. of Plymouth, on an eminence between Stonehouse creek on the E. and Hamoaze on the W. It is of modern date, and owes its origin, and rapid increase, to the establishment of the dock-yard and naval arsenals along the E. bank of Hamoaze. The king's dock-yard is one of the finest in the world, occupying near 72 acres, and having all the conveniences for building and fitting out ships of war: it is separated from the town by a high wall, and both are defended by strong fortifications. The governor of Plymouth now resides here, in a handsome house overlooking the harbour from a rocky eminence. Near it are six squares of barracks; and about half a mile distant are military hospitals for the sick. The town contains one church, two chapels (a third in the dock-yard) and several meeting-houses. The market-place is large, and a market, though not chartered, is held three times a week. Its trade and population, in time of war, is very considerable: in 1801, the number of its inhabitants was 23,747, exclusive of the military and persons belonging to the navy.

PLYMPTON, a borough in Devonshire, governed by a mayor, with a market on Saturday. It had once a castle, now in ruins; and is one of the stannary towns for tin. It is seated

near the Plym, seven miles E. of Plymouth, and 218 W. by S. of London.

PLYNLIMMON, a vast and lofty mountain of Wales, partly in Montgomeryshire, and partly in Cardiganshire. The Severn, the Wye, and other rivers, have their source in this mountain. According to the accurate observations of colonel Mudge, in the Trigonometrical Survey, the altitude of this mountain is 2,463 feet, its latitude 52. 28. 3 N. and its longitude 3. 46. 4 W.

PLYNTERIA, a festival among the Greeks, in honour of Minerva. The word seems to be derived from *πλυνειν*, *lavare*, because, during the solemnity, they undressed the statue of the goddess, and washed it.

PNEUMATIC. *a.* (*πνευματικός*.) Relating to the wind; or to the air; or finally to aeriform fluids.

PNEUMATIC APPARATUS. The discovery of aeriform fluids has, in modern chemistry, occasioned the necessity of some peculiar instruments, by means of which those substances may, in distillations, solutions, or other operations, be caught, collected, and properly managed. The proper instruments for this are styled the pneumatic apparatus. Any kind of air is specifically lighter than any liquid; and therefore, if not decomposed by it, rises through it in bubbles. On this principle rests the essential part of the apparatus, adapted to such operations. Its principal part is the pneumatic trough, which is a kind of reservoir for the liquid, through which the gas is conveyed and caused to rise, and is filled either with water or with quicksilver. Some inches below its brim an horizontal shelf is fastened, in dimension about half or the third part of the trough, and provided on its foremost edge with a row of holes, into which, from underneath, short-necked funnels are fixed. The trough is filled with water sufficient to cover the shelf, to support the receivers, which being previously filled with water or mercury, are placed invertedly, their open end turned down upon the above-mentioned holes, through which afterwards the gasses, conveyed there and directed by means of the funnels, rise in the form of air-bubbles.

In some cases the trough must be filled with quicksilver, because water decomposes some kinds of air by absorbing their basis. The price and specific gravity of that metal make it necessary to give to the quicksilver trough smaller dimensions. It is either cut in marble, or made of wood well joined. The late Karsten has contrived an apparatus, which, to the advantage of saving room, adds that of great conveniency.

To disengage gasses, retorts of glass, either common or tubulated, are employed, and placed in a sand-bath, or heated by the fire of a lamp. Earthen, or coated glass retorts, are put in the naked fire. If necessary, they are joined with a metallic or glass conveying pipe. When, besides the aeriform, other fluids are to be collected, the middle or intermediate bottle finds its use; and to prevent, after cooling, the rising of the

PNEUMATICS.

water from the trough into the disengaging vessels, the tube of safety is employed. For the extrication of gasses taking place in solutions, for which no external heat is required, the bottle called disengaging bottle, or proof, may be used. For receivers, to collect the disengaging airs, various cylinders of glass are used, whether graduated or not, either closed at one end, or open at both; and, in this last case, they are made air-tight by a stopper fitted by grinding. Besides these, glass-bells and common bottles are employed.

To combine with water, in a commodious way, some gasses that are only gradually and slowly absorbed by it, the glass apparatus of Parker is serviceable.

PNEUMATICS, as well as the word **PNEUMATOLOGY**, is derived from the Greek word denoting air, or, more properly, breath: but in their modern acceptation the terms differ widely, the latter denoting the science of the intellectual phenomena depending upon the operations or affections of the mind of man; while the former relates to that part of natural philosophy which treats of the mechanical properties of air, and the different elastic fluids. Thus pneumatics includes, as an important branch, the doctrine of aerostatics, common air being the most extensive and universal of the fluids which possess elasticity.

Previous to our entering upon the theoretic part of this science, it will be proper to relate some of the most obvious and natural experiments tending to prove the existence of the different mechanical affections which are usually ascribed to the air as a body: to this object we shall therefore appropriate a few of the following articles.

1. Air is a ponderous fluid which surrounds the earth.

For, that it is a fluid is obvious, because its parts are easily moved, and yield to the smallest inequality of pressure: and that it is ponderous will appear from the following considerations:

1. It always accompanies this globe in its orbit round the sun, surrounding it to a certain distance, under the name of the atmosphere, which indicates the being connected with the earth by its general force of gravity. It is chiefly in consequence of this that it is continually moving round the earth from east to west, forming what is called the trade-wind.

2. It is in like manner owing to the gravity of the air that it supports the clouds and vapours which we see constantly floating in it. We have seen bodies of no inconsiderable weight float, and even rise, in the air. Soap-bubbles and balloons filled with inflammable gas rise and float in the same manner as a cork rises in water. This phenomenon proves the weight of the air in the same manner that the swimming of a piece of wood indicates the weight of the water which supports it.

3. But we are not left to these refined observations for the proof of the air's gravity. We may observe familiar phenomena, which would be immediate consequences of the supposition that air is a heavy fluid, and, like other heavy fluids, presses on the outsides of all bodies immersed in or surrounded by it. Thus, for instance, if we shut the nozzle and valve hole of a pair of bellows, after having squeezed the air out of them, we shall find that a very great force, even some hundred pounds, is necessary for separating the boards. They are

kept together by the pressure of the heavy air which surrounds them, in the same manner as if they were immersed in water. In like manner, if we stop the end of a syringe after its piston has been pressed down to the bottom, and then attempt to draw up the piston, we shall find a considerable force necessary, viz. about 15 or 16 pounds for every square inch of the section of the syringe. Exerting this force, we can draw up the piston to the top, and we can hold it there: but the moment we cease acting, the piston rushes down and strikes the bottom. It is called a suction, as we feel something as it were drawing in the piston; but it is really the weight of the incumbent air pressing it in. And this obtains in every position of the syringe; because the air is a fluid, and presses in every direction. Nay, it presses on the syringe as well as on the piston; and if the piston be hung by its ring on a nail, the syringe requires force to draw it down (just as much as to draw the piston up); and if it be let go, it will spring up, unless loaded with at least 15 pounds for every square inch of its transverse section.

4. Let the air be exhausted from a glass vessel; and by means of a cock let the vessel be kept exhausted; if the vessel be weighed while it is exhausted, and then again when the air is re-admitted, there will be a manifest difference, exhibiting the weight of as much air as the vessel contained.

5. If a glass tube more than 31 inches in length, one end of which is closed up, be filled with mercury, and be held vertically, the other extremity being immersed in a vessel of the same fluid, then the mercury in the tube will descend from the upper extremity, and will remain suspended at some altitude between 28 and 31 inches from the surface of the external mercury: the suspension of the mercury is occasioned by the pressure of the external air upon the surface of the mercury in the vessel; when this pressure is removed by placing the tube and vessel under a receiver, and exhausting the air, the mercury will sink in the tube, and on re-admitting the air, will rise. This is called the Torricellian experiment.

The instrument here used is called a barometer; because the weight of a column of mercury whose base is the orifice of the tube, and altitude equal to that of the mercury in the tube above the surface in the reservoir, is equal to the weight of a column of air extending to the top of the atmosphere, and whose base is equal to the same orifice. And since the weight of this column of quicksilver, *ceteris paribus*, is at its altitude, it follows that the weight of the air is proportional to the altitude of the mercury in the barometer.

The altitude at which the mercury is sustained in the barometer, above the surface of the mercury in the reservoir, is called the standard altitude; and will be the same in any number of tubes, whatever be their bore or their position, provided the tube is not so very slender as to expose the mercury to a sensible alteration from the capillary attraction. The pressure of the atmosphere is equal to about 15lbs. avoirdupois upon every square inch, at the medium height of the mercury in the barometer: for a cubic foot of mercury weighs about 13568 ounces, and $\frac{13568}{1728} \times 29\frac{1}{2} = 233.6 \text{ oz.} = 14.6 \text{ lbs.}$

6. If a barometer tube, instead of being hermetically sealed at the top, be closely covered with a piece of bladder, the mercury will rise to the same height as in a common barometer; but on piercing

PNEUMATICS.

the bladder with a needle so as to admit the air, the mercury will fall: for in this case the weight of the air presses upon the mercury in the tube, and the weight of these two together must obviously preponderate over the contrary pressure, and destroy the equilibrium.

II. The pressure of the atmosphere varies at different altitudes.

Let a glass tube, open at both ends, be put through a cork into a large phial containing a small quantity of coloured water; let the lower end of the tube be in the water, and let the cork and tube be closely cemented to the neck of the bottle; then blow through the tube till the quantity of air within the phial is so increased that the water will rise above the neck of the phial. Let this phial be placed in a vessel of sand to keep the air within of the same temperature: then will the water stand at different heights in the tube, according to the elevation of the place where it is set; whence it appears that the pressure of the atmosphere varies at different altitudes. And the same thing will appear more clearly in a subsequent article. In ascending the mountain of Snowden, which is 3720 feet high, the barometer sunk 3·8 inches.

Hence the proportion of the specific gravity of air near the earth's surface to that of water may be ascertained. Thus, if the difference in height of the two places where the above experiment is made be 52 feet, and that difference cause a variation of $\frac{1}{2}$ of an inch in the height of the water, it follows, that a column of water of $\frac{1}{2}$ of an inch, or $\frac{1}{16}$ of a foot, is equiponderant to a column of air of 52 feet, having the same base: consequently the specific gravity of water is to that of air as 52 to $\frac{1}{16}$, or as 832 to 1.

III. Air is elastic, or capable of compression and expansion.

This is proved by various experiments: 1. By the great expansion of a small quantity of air in a bladder apparently nearly empty, when the air is removed from the external parts in the receiver. 2. By the extrusion of a fluid from a glass bubble, by the expansion of a bubble of air contained in it. 3. By the expulsion of the white and yolk of an egg through a small hole in the little end, by the expansion of the air contained in the greater end. 4. By putting an almost emptied bladder into a small box, and laying a proper weight on the lid, which, on exhausting the air, will be raised up by the expansion of the air in the bladder. 5. Also a bladder filled with air, and just made to sink with a weight, will upon exhaustion soon rise by the expansion of the contained air. 6. Glass bubbles and images filled with water so as to make them just sink in that fluid, will, on exhausting the air from the surface, rise to the top of the vessel. 7. Beer, cyder, water, and porous bodies, emit great quantities of air under the exhausted receiver. 8. A shrivelled apple, when put under an exhausted receiver, will have its coat distended by the internal air so as to look smooth. 9. If the open end of a tube, whose other end is closed, be immersed perpendicularly in water, the space occupied by the air will be diminished, as the depth of the tube or the upward pressure of the water is increased: or, if the shorter leg of a bent tube be closed, and mercury poured into the longer, the air will be compressed in the shorter leg into a space continually decreasing as the quantity of pressing mercury is increased; and if some of the mercury be taken from the longer leg, the air in the shorter will ex-

pand and occupy a proportionably larger space. 10. The mercury may be raised by the expansion of a small quantity of confined air to the same height in an exhausted tube above the air-pump, as that to which it is raised in the mercurial gauge by the pressure of the atmosphere below it.

The limits of the condensation and rarefaction of air by human powers are not ascertained. Dr. Hales found, that when dry wood was put into a strong vessel, which it almost filled, and the remainder was filled with water, the swelling of the wood, occasioned by its imbibition of water, condensed the air of his gauge into the thousandth of its original bulk. He found that pease treated in the same way generated elastic air, which pressing on the air in the gauge condensed it into the fifteen hundredth part of its bulk. This is the greatest condensation that has been ascertained with precision, although in other experiments it has certainly been carried much further; but the precise degree could not be ascertained.

The only use to be made of this observation at present is, that since we have been able to exhibit air in a density a thousand times greater than the ordinary density of the air we breathe, it cannot, as some imagine, be only a different form of water; for in this state it is as dense or denser than water, and yet retains its great expansibility.

Another important observation is, that in every state of density in which we find it, it retains its perfect fluidity, transmitting all pressures which are applied to it with undiminished force, as appears by the equality constantly observed between the opposing columns of water or other fluid by which it is compressed, and by the facility with which all motions are performed in it in the most compressed states in which we can make observations of this kind. This fact is totally incompatible with the opinion of those who ascribe the elasticity of air to the springy ramified structure of its particles, touching each other like so many pieces of sponge or foot-balls. A collection of such particles might indeed be pervaded by solid bodies with considerable ease, if they were merely touching each other, and not subjected to any external pressure. But the moment such pressure is exerted, and the assemblage squeezed into a smaller space, each presses on its adjoining particles: they are individually compressed, flattened in their touching surfaces, and before the density is doubled they are squeezed into the form of perfect cubes, and compose a mass, which may indeed propagate pressure from one place to another in an imperfect manner, and with great diminution of its intensity, but will no more be fluid than a mass of soft clay.

IV. The elastic force of the air is equal to the force of compression.

For if the air be exhausted from an open tube whose lower part is immersed in a vessel containing mercury, the air within the vessel being prevented from escaping, then will this air by its elasticity force the mercury up the tube very nearly to the same height as it would be raised by the pressure of the atmosphere.

This proposition is sometimes proved independent of experiments in the following manner: if the force with which the air endeavours to expand itself when it is compressed were less than the compressing force, it would yield still further to that force; if it were greater, it could not have yielded so far. Consequently, when any force has so compressed the air that it remains at rest, the force

PNEUMATICS.

of the air arising from its elasticity can neither be greater nor less than the compressing force; that is, it must be equal to it.

But it must be confessed that, in this case, the experimental proof is the most satisfactory.

V. The elasticity of air not very different from its natural state is inversely as the space occupied by it.

1. Let a cylindrical tube BC (fig. 4. pl. 139.), open at one end B, be filled with mercury to an altitude equal to BD before inversion, and after the immersion of B in a basin of mercury, the air, which before occupied a space equal to CD, is dilated through a larger space as CA, and if BN be the standard altitude (art. I. 5.), depresses the mercury from N to A. Now the elastic force of air in its natural state, or occupying a space equal to CD (E), is to the elastic force of air occupying the space BD (e) as the columns of mercury which they are capable of supporting (art. 4.); that is, as BN to AN: but it is collected from experiments that BN : AN :: AC : CD; consequently AC : CD :: E : e.

And the same thing may be otherwise shown by experiments with bent tubes.

Hence since the density of the air is inversely as the magnitude of space occupied (art. 10.), it is, therefore, as the elasticity, or as the compressing force (art. 4.): so that, putting D for the density, C the compressing force, E the force of elasticity, and S the space, we have $C \propto D \propto E \propto \frac{1}{S}$. These relations, however, are confined within very narrow limits, for it has been asserted that when the air is compressed into a space only four times less than the space it occupies in its natural state, it does not then vary inversely as the force of compression, the resistance increasing much more rapidly. Comment. Bonon. vol. I. p. 209, &c.

The experiments of Boyle, Mariotte, and Amontons, were not extended to very great compressions: so that they found generally that the elasticity of the air was proportioned to its density; and the law was long acquiesced in, being called the Boylean law. But later philosophers have carried the compression much further. Thus Sulzer compressed air into $\frac{1}{8}$ of its former dimensions: the results of his experiments are exhibited in the following table, where the column D shows the densities, and those marked E the corresponding elasticities,

First Set.		Second Set.		Third Set.	
D	E	D	E	D	E
1 000	1 000	1 000	1 000	1 000	1 000
1 100	1 093	1 236	1 224	1 091	1 076
1 222	1 211	1 294	1 288	1 200	1 183
1 375	1 284	1 375	1 332	1 333	1 303
1 571	1 599	1 466	1 417	1 500	1 472
1 692	1 669	1 571	1 515	1 714	1 659
1 833	1 796	1 692	1 647		
2 000	1 938	2 000	1 964	2 000	1 900
2 288	2 130				
2 444	2 375	2 444	2 392	2 400	2 241
3 143	2 936	3 143	3 078	3 000	2 793
3 666	3 391	3 666	3 575		
4 000	3 706			4 000	3 631
4 444	4 035	4 444	4 320		
4 888	4 438				
5 500	4 922	5 500	5 096		
5 882	5 522	7 333	6 694	6 000	5 297
				8 000	6 835

Other experiments for the same purpose were instituted by professor Robison, the results of which may be seen below.

Dry Air.		Moist Air.		Camp. Air.	
D	E	D	E	D	E
1 000	1 000	1 000	1 000	1 000	1 000
2 000	1 957	2 000	1 920	2 000	1 909
3 000	2 848	3 000	2 839	3 000	2 845
4 000	3 737	4 000	3 726	4 000	3 718
5 500	4 930	5 500	5 000	5 500	5 104
6 300	5 342	6 000	5 452	6 000	5 463
7 620	6 490	7 620	6 775	7 620	6 812

Here it appears again in the clearest manner that the elasticities do not increase so fast as the densi-

ties, and the differences are even greater than in Mr. Sulzer's experiments.

PNEUMATICS.

The second table contains the results of experiments made on very damp air in a warm summer's morning. In these it appears that the elasticities are almost precisely proportional to the densities + a small constant quantity, nearly 0.11, deviating from this rule chiefly between the densities 1 and 1.5, within which limits we have very nearly $D = E^{1.007}$. As this air is nearer to the constitution of atmospheric air than the former, this rule may be safely followed in cases where atmospheric air is concerned, as in measuring the depths of pits by the barometer.

The third table shows the compression and elasticity of air strongly impregnated with the vapours of camphire. Here the Boylean law appears pretty exact, or, rather, the elasticity seems to increase a little faster than the density.

VI. Heat increases the elasticity of the air, and cold diminishes it. Or, heat expands and cold condenses the air.

This property is likewise proved by experience.

1. Tie a bladder very close with some air in it, and lay it before the fire: then as it warms it will more and more distend the bladder, and at last burst it, if the heat be continued, and increased high enough. But if the bladder be removed from the fire, as it cools it will contract again, as before. Indeed it was upon this principle that the first air-balloons were made by Montgolfier: for, by heating the air within them, by a fire underneath, the hot air distends them to a size which occupies a space in the atmosphere, whose weight of common air exceeds that of the balloon.

2. Also, if a cup or glass, with a little air in it, be inverted into a vessel of water; and the whole be heated over the fire, or otherwise; the air in the top will expand till it fill the glass, and expel the water out of it; and part of the air itself will follow, by continuing or increasing the heat.

Many other experiments to the same effect might be adduced.

The expansion of air, though exposed to the same degree of heat, is not the same in experiments made at different times, owing to the difference of density, coldness, humidity, &c. The expansive force of hot steam may exceed the force of gunpowder more than 30 times, and indeed is irresistible when the force is intense. Hence it follows, that when air is much impregnated with water it will possess an expansive power by heat, much greater than that of pure air. Whether the degree of expansion in pure air be proportional to that of the heat by which it is produced, is not known; but it is manifest that the variation of space occupied by a portion of air exposed to different degrees of heat may be sufficient to convey a tolerable idea of the actual quantity of heat. Upon this principle, therefore, have been constructed air thermometers, to exhibit small variations of heat.

There is no general rule for the degree of expansion to which different bodies are subject by being exposed to the same degree of heat. Taking an average, however, it has been found, by experiment, that for each degree of heat measured, by Fahrenheit's thermometer, mercury, water, and air, expand by the following parts of their own bulk, viz.

Mercury the 9600th	} part of its own bulk.
Water..... 6666th	
Air 435th	

In mercury the corresponding expansions for 1° gradually diminish, being expressed by .0001177 at 2° of the thermometer, and by .0000783 at 212°:

but at 12° the expansion corresponding to a degree of variation in heat is .0001160, and at 102° it is .0001003, so that between these limits the variation in the measure of expansion is very trifling. Taking into the estimate the changes in the expansion, &c. the specific gravities of these fluids at different temperatures have been stated as below.

Spec. grav. of air 1	} when the barom. is at 29.27, and the thermom. at 53°.
water . . . 836	
mercury 11365	
Or thus, air 1	} when the barom. is 29.27, and the thermom. at 55°.

On this subject the student may advantageously consult general Roy's paper in the Phil. Trans. vol. 67. Also sir Geo. Shuckburgh's and M. De Luc's papers in the same volume.

Equilibrium of elastic fluids.

VII. PROP.—To investigate equations of equilibrium for elastic fluids.

This will be very easy, if we consider that such fluids must, from the nature of perfect elasticity, occupy a smaller space in proportion as the forces which compress them are greater, and restore themselves to their primitive volumes, when the action of the compressing forces cease. Let, then, P be a pressure exerted upon a quantity M of the fluid, whose density is D ; p another pressure, m the mass or volume the fluid takes in consequence of this pressure, and d the density of this mass; so shall we have these equations:

$$PM = pm, MD = md, \text{ and } Pd = pD \dots\dots (I.)$$

When $P = p$, then $M = m$, as is obvious.

These values only give the pressures exerted upon a unit of surface; but if we drop the consideration of gravity, or any other force which may cause a variation of density in the different parts of the fluid, we may then reason from the principles of hydrostatics. This granted, the pressure p exerted upon any surface denoted by a will be

$$p = \frac{ad}{D}P, \text{ or } p = \frac{aM}{m}P \dots\dots\dots (II.)$$

Pressures being commonly valued by weights, we may represent that which is exerted upon a unit of surface by the weight of a prism of the same fluid whose height will be given. Let H be the height corresponding to P , and h to p ; then we have HD for the mass of this prism, and HDg its weight (g denoting the force of gravity): hence $P = HDg$; and in like manner $p = hdg$. Substituting these for P and p in the equations marked (I.) above, we have $hD = Hd$, and $hm = HM$. Whence we learn that the property of non-elastic fluids obtains likewise with regard to elastic fluids.

Instead of taking the same fluid, we may employ

PNEUMATICS.

another whose density is δ ; and, by proceeding in a similar manner, get the following general equation for the pressure,

$$p = \frac{M}{m} ag\delta H = \frac{d}{D} ag\delta H \dots \dots \dots (III.)$$

Many other equations might be deduced with equal facility; but those here given are among the most useful.

VIII. PROP.—If an elastic fluid be quiescent, and composed of particles equally repulsive at equal distances, and at unequal distances, repelling each other according to any law of the distance, its density will be uniform.

For if the distances of any two particles from an intermediate particle be unequal, their repulsive forces must be unequal, and, of consequence, motion must ensue; which is contrary to the hypothesis: therefore the fluid must have its particles at equal distances, or be uniformly dense.

COR.—If any portion of an elastic fluid be uniformly dense, and equally compressed on all sides, it must be quiescent.

IX. PROP.—If the component particles of a uniform cubical mass of a fluid repel each other, with forces varying according to any inverse or direct ratio of their distances (less than the direct duplicate), the fluid will be elastic.

For the whole repulsive force of any surface of the fluid is as the number of particles in that surface, and the force of each, or as the number in L the length of that surface, into the number in B the breadth, into the force of each particle; or, substituting R for the whole repulsive force of the surface, I for the interval or distance between two contiguous particles, and F for the force with which they repel each other, R will vary as $\frac{F}{I^2}$.

Hence, if F vary in any inverse ratio, or any direct ratio less than the duplicate ratio of I , R will vary in some inverse ratio of I , which is a necessary condition of elastic fluids.

X. PROP.—If the particles of an elastic fluid repel each other with forces varying inversely, as the n th power of their distances, that is, as $\frac{1}{I^n}$, and the compressing force C upon any surface be equal to its whole repulsive force R , then will C vary as that power of the density D , whose exponent is $\frac{n+2}{3}$.

For, let a portion of the fluid be contained in a given cubic space, one of whose faces is the rectangle of $L \times B$, the compressing force being applied to that surface. Now, the number of particles in the given square surface is as $\frac{1}{I^2}$; and, by hypothesis, the force F , with which two particles repel each other, is as $\frac{1}{I^n}$; therefore the elastic force of the fluid, and of consequence the compressive force C , is as $\frac{1}{I^2} \times \frac{1}{I^n}$, or as $\frac{1}{I^{n+2}}$. But the density of the fluid contained in the given cubical space is inversely as the cube of the distance between the centres of the particles; that is, $D \propto \frac{1}{I^3}$, and

$I \propto \frac{1}{D^{\frac{1}{3}}}$: whence, by substituting $D^{-\frac{1}{3}}$ for I , in

the expression $C \propto \frac{1}{I^{n+2}}$, we have $C \propto D^{\frac{n+2}{3}}$.

COR. 1. Conversely, if $D^{\frac{n+2}{3}}$ vary as C , the repulsive force of each particle, or F , must vary as $\frac{1}{I^n}$.

For the quantity of matter being given, $D \propto \frac{1}{L^3}$

$\propto \frac{1}{I^3}$ and $D^{\frac{n+2}{3}}$ will vary as $\frac{1}{I^{n+2}}$: but F varies

as C divided by the number of particles in L^2 ,

or as $C \times I^2$, or $\propto D^{\frac{n+2}{3}} \times I^2$, or $\propto I^2 \div I$ or

$\propto \frac{1}{I}$.

COR. 2. Hence again we see, since $n+2$ must be always positive to make C positive, that n must be either some whole positive number, or a negative number less than 2, in order to constitute a fluid of particles which repel each other.

COR. 3. If water be supposed compressible in a very small degree, the particles must be kept at a distance by some repulsive force, while D remains

nearly constant. Now, since $C \propto D^{\frac{n+2}{3}}$, we shall

have $D \propto C^{\frac{3}{n+2}}$; in which, that $C^{\frac{3}{n+2}}$ may be nearly invariable, n must be a very great number: hence, according to this hypothesis, the repulsive force of the particles of water varies inversely in a very high power of their distances.

COR. 4. When the density of the fluid varies as the force which compresses it, or $D \propto C$, the ex-

pression $C \propto D^{\frac{n+2}{3}}$ becomes $C \propto D^{\frac{1+2}{3}}$ and $n=1$;

whence $F \propto \frac{1}{I^n}$ becomes $F \propto \frac{1}{I}$, or the force of each particle is inversely as the interval between two contiguous particles.

COR. 5. Hence, because the density of the air is nearly proportional to the force which compresses it, (art. 4.) its constituent particles must repel one another with forces varying inversely as their distances.

COR. 6. The density of the air varying as the compressing force, and that perpetually decreasing in ascending the atmosphere, the density and elasticity of the air also perpetually decrease.

DEF. A homogeneous atmosphere is an atmosphere supposed to be of the same weight as that which actually surrounds the earth; its density being uniform, and every where equal to the density of the air at the earth's surface.

XI. PROP.—To find the altitude of a homogeneous atmosphere.

Let H be the height of the homogeneous atmosphere, its uniform density being D , the same as the density of the air pressing upon the mercury in the basin of the barometer; h the height of the mercury in the barometer tube, and d the density of that fluid: then (art. 7.) we have $M=m$, or $HD=hd$,

$$\text{whence } H = \frac{hd}{D}.$$

PNEUMATICS.

Now it appears from article 6, that when the densities of air and mercury D and d are as $1\frac{1}{2}$ and 13600, the height h of the mercury in the barometer is $2\frac{1}{2}$ feet.

$$\text{Hence } H = \frac{hd}{D} = \frac{13600 \times 2\frac{1}{2}}{1\frac{1}{2}} = 27818 \text{ feet,} =$$

5.268 miles. So that the height of the homogeneous atmosphere is rather more than $5\frac{1}{4}$ miles.

COR. 1. If it were not for the changes of temperature, the height H of the homogeneous atmosphere would be invariable whatever might be the height of the mercury in the barometer.

For if d be constant, because the specific gravity of air varies as D its density, and this again as h , the height of the mercury in the tube, it follows that $\frac{h}{D}$ is invariable, and consequently $H = \frac{hd}{D}$ is constant likewise.

XII. PROP.—Supposing the force of gravity to vary as the n th power of the distance from the centre of the earth, and the compressive force to vary as the density, to find the relation between the density of the air and the altitude above the surface of the earth.

Let x represent the variable distance from the surface of the earth, the radius of the earth being unity, d the density of the air at the distance x , and H the height of the homogeneous atmosphere. Now, since by hypothesis the compressing force varies as the density, the fluxion of the former will vary as the fluxion of the latter: while, at any distance, x the fluxion of the compressing force must vary as the force of gravity, the density, and the fluxion of the altitude, conjointly; so that the fluxion of the compressing force will be to that of

the density in the constant ratio of $x \cdot d \cdot \dot{x}$ to $-\dot{d}$, the latter fluxion having the negative sign, because the density decreases while the altitude increases. Consequently, since by the definition of a homogeneous atmosphere H will represent the compressing force at the surface of the earth, we have

$$H:1::x \cdot d \cdot \dot{x}:-\dot{d}, \text{ whence } x \cdot \dot{x} = -H \times \frac{\dot{d}}{d}, \text{ and}$$

$$\frac{n+1}{n+1} = -H \cdot \text{hyp. log. } d + C.$$

Now to correct the fluent we must consider that, when $x=1, d=1$; whence we find $C = \frac{1}{n+1}$ for the value of the constant quantity: and the correct

$$\text{fluent is } \frac{x^{n+1}}{n+1} = \frac{1}{n+1} - H \cdot \text{hyp. log. } d. \text{ Hence}$$

$$\frac{1-x^{n+1}}{n+1} = H \cdot \text{hyp. log. } d.$$

which is the general equation expressing the relation between the altitude and the density.

COR. 1. When the force of gravity varies inversely as the square of the distance, $n = -2$, and

$$\frac{1-x^{-1}}{-1} = H \cdot \text{hyp. log. } d, \text{ becomes } \frac{1}{x} - 1 = H \cdot \text{hyp. log. } d. \text{ So that if } x \text{ increase in harmonic pro-}$$

gression, $\frac{1}{x}$ will decrease in arithmetic progression, and consequently hyp. log. d will decrease in arithmetic progression.

COR. 2. If the force of gravity be supposed constant $n=0$, and $1-x=H \cdot \text{hyp. log. } d$. Consequently, if x increase in arithmetic progression,

since $1-x$ will then decrease in arithmetic progression, the hyp. log. of d will decrease in arithmetic progression.

COR. 3. Since the hyperbolic logarithms are to the common logarithms in a constant ratio, viz. that of 1 to .43429448, &c. it follows that when x increases in arithmetic progression the common logarithms of the densities will decrease in arithmetic progression, and the densities themselves in geometrical progression, on the supposition of equal gravity.

COR. 4. Hence, retaining the same hypothesis; different altitudes above the earth's surface will vary as the negative logarithms of the densities or weights of air at those altitudes. So that if D and d denote the densities at the heights H and h , since

$$H \propto -\log. D, \text{ and } h \propto -\log. d, \text{ the difference}$$

$$H-h \propto -\log. D - (-\log. d) \propto \log. D - \log. d,$$

or $\propto \log. \frac{D}{d}$. And if $H=0$, or $D=\text{the density at the earth's surface}$, then any altitude above the surface is as the log. of $\frac{D}{d}$. Or generally the log.

of $\frac{D}{d}$ varies as the altitude of the one place above

the other, whether the lower place be at the surface of the earth or not: and upon this property is founded the method of finding the heights of mountains, &c. by the barometer. See ATMOSPHERICAL LOGARITHMIC.

On the motion of air when the equilibrium of pressure is removed.

XIII.—Here we shall consider air (taken for a representative of elastic fluids in general) as acted upon by gravity equally and in parallel directions; and in a series of propositions enquire into the circumstances of its passage from a vessel into a vacuum, or from one vessel to another, in which the air is of less density.

PROP. To determine with what velocity air will rush into a void space when impelled by its weight alone.

This is manifestly analogous to the hydraulic problem of water flowing through an orifice in the bottom or side of a vessel, and the manner of demonstration there adopted will immediately apply to the present instance. For when the moving force, and the matter to be moved, vary in the same proportion, the velocity will continue the same; that is, since $F \propto BV$, when $F \propto B, V$ is constant.

If, therefore, there be similar vessels of air, water, oil, or any other fluid, all of the height of a homogeneous atmosphere, they will be discharged through equal and similar holes with the same velocity: for, in whatever proportion the quantity of matter moving through the hole be varied by a change of density, the pressure which forces it out, acting in circumstances perfectly similar, varies in the same proportion. Hence it follows, that air rushes from the atmosphere into a void with the velocity which a heavy body would acquire by falling from the top of a homogeneous atmosphere.

Let us take, then, for the height of the homogeneous atmosphere $H=27818$ feet (art. 11.); and if we put $g=32\frac{1}{2}$ feet, as we have heretofore

done, we shall have $V = \sqrt{2gH} = 1339$ feet nearly $\approx 8\sqrt{H}$ nearly, the velocity sought: no regard being here paid to the velocity which the air ac-

PNEUMATICS.

quires after its issuing into the previous void, by its continual expansion.

SCHOLIUM.

XIV. The first solution to this problem we recollect was given by Dr. Papin in the Phil. Trans. No. 184. See also the new abridgment, part x. p. 334. It is deduced from this proposition, viz. that of different liquors under the same pressure, those specifically lighter must acquire a greater celerity, and their different velocities will be to one another as the roots of the specific gravities of the said liquors. "If, therefore," says Dr. Papin, "we would know what is the velocity of air when driven by any degree of pressure whatever, we need only find what would be the velocity of water under the same pressure, and then take the square roots of the specific gravities of these two fluids, because, as much as the square root of the specific gravity of water exceeds the square root of the specific gravity of the air, so much in proportion will the velocity of the air exceed that of the water. For example, when I would compute what would be the velocity of a bullet shot by the pneumatic engine, described in Phil. Trans. No. 179, I should first compute what was the velocity of the air itself that drove the bullet: I therefore observe that on this occasion the air sustains a pressure much about the same as that of water when its head is 32 feet high; now such water would spout out with a sufficient velocity to ascend 32 feet perpendicular, and therefore it has the velocity of 45 feet in a second. It remains, therefore, only to know the proportion of the gravity of air to that of water: this we have found not to be always the same, because the height, the heat, and the moisture of the atmosphere, are variable; yet we may say in general, that the ratio of the specific gravities of water and air is about 840 to 1. Taking then their square roots, which are 29 and 1, we may conclude that the velocity of air must exceed that of water 29 times; and so multiplying 45, the velocity of water, by 29, we shall find that the velocity of the air, driven by the whole pressure of the atmosphere, is about 1305 feet in a second."

This number, as Dr. Hutton remarks, is too small; for the mean pressure of the atmosphere is now known to be about that of a column of water of 33½ feet, and this will give for its velocity 46½ feet, instead of 45; which, multiplied by the 29, gives nearly 1348 feet: a determination which differs from that in the preceding article by about its 150th part.

XV. PROP.—To determine the velocity with which the air of the atmosphere will rush into a space containing rarer air.

Whatever the density of the rarer air may be, its elasticity, which varies as its density, will balance a proportional part of the pressure of the atmosphere; and it is the excess of this last only which is the moving force, the matter to be moved is the same as before. Let D then be the natural density of the air, and δ the density of the air contained in the vessel into which it is supposed to run: let P be the pressure of the atmosphere, and therefore equal to the force which impels it into a void, and π the force with which this rarer air would run into a void. Then (art. 7.) we have $P\delta = \pi D$,

and $\pi = \frac{P\delta}{D}$. Also the moving force in the present case is $P - \pi$, or $P - \frac{P\delta}{D}$. Lastly, let V be the velocity of air of density D rushing into a void,

and v the velocity with which it will rush into the rarified air of density δ . Now, in this as well as other fluids, the pressures are as the squares of the

velocities of efflux: therefore $P : P - \frac{P\delta}{D} :: V^2 : v^2$,

and by reduction we find $v = V \times \sqrt{1 - \frac{\delta}{D}}$; an

expression for the velocity sought, not considering the resistance which the air of density D will experience from the inertia of that in the vessel, which it must displace in its motion.

COR. 1. Hence it appears that there will always be a current into the vessel while δ is less than D .

COR. 2. Hence, also, we learn the gradual diminution of the velocity as the vessel fills; for, because δ gradually increases, $1 - \frac{\delta}{D}$, and conse-

quently the value of v continually diminishes.

XVI. PROP.—To determine the time t in seconds, in which the air of the atmosphere will flow into a given vessel from its state of vacuity, till the air in the vessel has acquired any proposed density δ .

Let H be the height in feet due to the velocity V , s the solid content or capacity of the vessel in cubic feet, and a the area or section of the aperture in square feet, D representing, as before, the natural density of the air. Now, since the quantity of air to fill the vessel will depend upon its density and the capacity of the vessel conjointly, we may express it by Ds when the air is in its ordinary state, and by δs when it has acquired the density δ . To find the rate at which the vessel fills we must take the fluxion of the quantity δs , which will be $s\dot{\delta}$, because s is invariable. The velocity of influx

at the first instant is V or $\sqrt{2gH}$, and when the air in the vessel has acquired the density δ , that is, at the end of the time t , the velocity is $\sqrt{2gH} \times$

$\sqrt{1 - \frac{\delta}{D}}$, or $\sqrt{2gH} \cdot \frac{D - \delta}{D}$. Hence the rate

of influx, which may be measured by the indefinitely small quantity of air which will enter during the time t with this velocity, will be denoted by

$\sqrt{2gH} \times \sqrt{\frac{D - \delta}{D}} \times D a t = a t \sqrt{2gDH (D - \delta)}$.

Making these two values of the rate of influx equal,

we have $a t \sqrt{2gDH (D - \delta)} = s\dot{\delta}$, or $t = \frac{s}{\sqrt{2gDH}} \times \frac{\dot{\delta}}{D - \delta}$. Taking the fluents, we have $t =$

$\frac{s}{\frac{1}{2} a \sqrt{2gDH}} \times \sqrt{D - \delta} + C$.

To determine the constant quantity C we must recollect that when $t = 0$, $\delta = 0$, and $\sqrt{D - \delta} = \sqrt{D}$; hence $C = \sqrt{D}$, and the correct fluent is

$t = \frac{s}{a \sqrt{\frac{1}{2}gDH}} \times (\sqrt{D - \delta} - \sqrt{D})$.

COR. When $\delta = D$ the motion ceases, in which case t becomes $\frac{s\sqrt{D}}{a \sqrt{\frac{1}{2}gDH}}$, or $\frac{s}{a \sqrt{\frac{1}{2}gH}}$, or $\frac{s}{4a\sqrt{H}}$ nearly, for the time of completely filling the vessel.

PNEUMATICS.

XVII.—To illustrate this by an example in numbers, let us suppose the capacity of the vessel to be 8 cubic feet, or nearly a wine hogshead, and that the orifice by which the air of the ordinary density (which we shall make=1) enters, is an inch square, or $\frac{1}{144}$ of a foot. Here $4\sqrt{H}=4\sqrt{27818}=668$, and $t=\frac{8}{\frac{1}{144} \cdot 668}=\frac{1152}{668}=1.7245$. If

the hole be only $\frac{1}{100}$ of a square inch, or the side $\frac{1}{10}$ of an inch, the time of completely filling the vessel will be nearly $172\frac{1}{2}$ seconds, or rather less than 3 minutes.

If we make the experiment with a hole cut in a thin plate, we shall find the time greater nearly in the ratio of 62 or 63 to 100. As is likewise the case with water flowing through small orifices, and for similar reasons.

In like manner we can find the time necessary for bringing the air in the vessel to $\frac{1}{4}$ of the ordinary density. For the only variable part of the correct

fluent above is $\sqrt{D-\delta}$, which in this case becomes

$\sqrt{1-\frac{1}{4}}=\sqrt{\frac{3}{4}}=\frac{\sqrt{3}}{2}$, whence $\sqrt{D}-\sqrt{D-\delta}=\frac{\sqrt{3}}{2}$. And if the hole is a square, each side being $\frac{1}{10}$ of an inch, the time is $\frac{1}{4}$ of $172\frac{1}{2}$, that is, $86\frac{1}{4}$ seconds.

XVIII. PROP.—Let the air in the vessel ABCD (fig. 5, pl. 139.) be compressed by a weight acting on the cover AD, which is moveable down the vessel, to determine the velocity of the air expelled at the aperture C.

The density D of the external air corresponds to its pressure P: and, since the immediate effect of the external pressure is to compress the air in the vessel and give it another density, let the additional pressure on the cover of the vessel be p , and the density of the air in the vessel be d ; then shall we

have $P : P+p :: D : d$; whence $p = P \times \frac{d-D}{D}$. Now,

because the pressure which expels the air is the difference between the force which compresses the air in the vessel and that which compresses the external air, the expelling force is p , and because the quantities of motion are as the forces which similarly produce them, we shall have $P : P \cdot \frac{d-D}{D} ::$

$MV : mv$, where M and m express the quantities of matter expelled, V the velocity with which air rushes into a vacuum, and v the velocity required. But because the quantities of aerial matter which issue from the same orifice in an instant are as the densities and velocities jointly, we shall have $MV :$

$mv :: DVV : dvv$. Consequently $P : P \cdot \frac{d-D}{D} :: DV^2 :$

dv^2 . And hence we deduce $v = V \sqrt{\frac{d-D}{d}}$.

COR. Another expression for the velocity may be obtained without considering the density: for since $P : P+p :: D : d$, therefore $d = \frac{D(P+p)}{P}$, and

$d-D = \frac{D(P+p)}{P} - D = \frac{D(P+p) - DP}{P} = \frac{Dp}{P}$;

whence $\frac{d-D}{d} = \frac{DP}{P} \cdot \frac{D(P+p)}{P} = \frac{p}{P+p}$. Substitut-

ing this value of $\frac{d-D}{d}$ for it in the final value of v,

it becomes $v = V \sqrt{\frac{p}{P+p}}$, which is both a simple and convenient expression.

XIX. PROP.—To enquire into the effect of the air's elasticity, when ascertaining the velocity with which the air will issue from a vessel into a vacuum.

Let ABCD (fig. 5, pl. 139.) be a vessel containing air of any density D. This air is in a state of compression, and if the compressing force be removed it will expand, and its elasticity will diminish with the density. Now its elasticity in any state is measured by the force which keeps it in that state (art. 4.); and the force which keeps common air in its ordinary density is the pressure of the atmosphere, which (art. 1.) is at a medium the same with the weight of a column of mercury $29\frac{1}{2}$ inches high. If, therefore, we suppose that this air, instead of being confined by the top of the vessel, is pressed down by a moveable piston carrying a cylinder of mercury of the same base, and $29\frac{1}{2}$ inches high, its elasticity will balance this pressure just as it does the pressure of the atmosphere: and, since it is a fluid, and propagates through every part and in every direction the pressure exerted on any one part, it will press on any small portion of the vessel by its elasticity, in the same manner as when loaded with this column. Hence, if this small portion of the vessel be removed, and a passage made into the void, the air will begin to flow out with the same velocity as it would flow out when impelled by its weight alone, or with the velocity acquired by falling from the top of the homogeneous atmosphere; that is, a velocity of 1339 feet nearly (art. 13.). But as soon as any air has passed through the orifice, the density of that remaining in the vessel is diminished, and its elasticity is diminished, consequently the expelling force is diminished: but the matter to be moved is diminished in the very same proportion as the density, the capacity of the vessel remaining unchanged: therefore, since the density and elasticity follow the same law, the quantity of matter moved will vary as the moving force, and the velocity will continue the same from the beginning to the end of the efflux.

SCHOLIUM.

XX.—Hence, since the velocity with which the air issues out of such a vessel is constant, we may readily compare the velocity of theory in art. 13, with that found by experiment. But for this purpose we shall here describe the simple apparatus and experiments of Mr. Banks, in which a change of density is avoided. (Banks on the Power of Machines, p. 10.) A (fig. 6. pl. 139.) is a cask of known capacity, into the top of which is screwed an aperture a of a known area. The tube Td, recurve at d, is soldered or screwed into the top of the said cask. The hole a is stopped, and water poured into the tube T till it is full; at which time a quantity of water will have passed out of the tube at d, and condensed the air in the cask till its spring is equal to the weight of the water in the tube. At this time a cock placed over the tube T, sufficiently large to supply water as fast as it can descend into the vessel A, must be opened to keep the tube constantly filled: for this purpose one person must attend it, and another must open the aperture a, which need only have been closed by a finger, and he must measure the seconds from the moment that the finger is removed till

PNEUMATICS.

the water flies out at the jet. Hence, from knowing the capacity of the vessel and the area of the jet, the velocity may be obtained. If the tube Td should be continued nearly to the bottom of A, while A was filling with water, the length of the compressing column would be gradually diminished, and of consequence the pressure would be constantly changing: to avoid any irregularity this might produce, the open end of the tube is as near the top of the cask as is consistent with a free passage for the water.

Experiments. The vessel contained 15lb. 6oz. of water; from which we find its capacity 425.088 cubic inches. The area of the aperture a , through which the air is discharged, is .0046 inches.

- Exp. I. $\left\{ \begin{array}{l} \text{The altitude of T above the cask 30 inches;} \\ \text{Time of expelling the air } 33^s, \text{ by several trials.} \end{array} \right.$
- Exp. II. $\left\{ \begin{array}{l} \text{The altitude of T 6 feet;} \\ \text{Time of expelling the air } 21.3^s, \text{ by several trials.} \end{array} \right.$

In the first experiment 425.088, the capacity of the cask, being divided by .0046, the area of the hole, gives 92410.4 inches, for the length of the

stream driven out in 33^s. Hence $\frac{92410.4}{12 \times 33} = 233.3$ feet, the velocity per second.

From the second experiment we deduce, by a similar process, 361.6 feet, for the velocity per second: and, to show the correspondence of this with the first, say, as $\sqrt{24}$ (the head) : 233.3 :: $\sqrt{6}$ (the head) : 361.8 feet; differing from the former by only a fifth of a foot.

To compare the velocity thus found by experiment with that assigned by theory (art. 13), we may say, as $\sqrt{6}$: 361.6 :: $\sqrt{33}$ (the height of a column of water equivalent in pressure to the atmosphere) : 845.2 feet, the velocity with which the atmosphere would begin to enter into a vacuum. Making the allowance spoken of in art. 17, we shall have $1339 \times .63 = 843.57$, agreeing as nearly with the experimental result as can reasonably be expected.

XXI. PROP.—To find the quantity of aerial matter which will be expelled from the orifice C of the vessel ABCD (fig. 5.) during any time t , and the density of the remaining air at the end of that time.

In the element of time i there issues (by art. 16.)

the capacity of air $ai\sqrt{2gH}$, the velocity V being constant (art. 19.), and consequently the quantity

of air $adi\sqrt{2gH}$. On the other hand, the quantity of air at the beginning of the efflux was sD , s being, as before, the capacity of the vessel; and when the air has acquired the density d , the quantity in the vessel is sd , and $sD - sd$ is the quantity expelled: consequently the quantity discharged

in the element of time i must be the fluxion of $sD - sd$; that is, $-sd$. Hence we have the equation

$adi\sqrt{2gH} = -sd$, and $i = \frac{-sd}{ad\sqrt{2gH}} = \frac{s}{a\sqrt{2gH}} \times$

$-\frac{d}{a}$. The fluent of this is $t = \frac{s}{a\sqrt{2gH}} \times \text{hyp. log.}$

d . Now this fluent must be so taken that when $t=0$, $d=D$, or $\text{hyp. log.} \frac{D}{d} = \text{hyp. log. } 1 = 0$. So

that the correct fluent is $t = \frac{s}{a\sqrt{2gH}} \times \text{hyp. log.} \frac{D}{d}$.

$\frac{s}{8a\sqrt{H}} \times \text{hyp. log.} \frac{D}{d}$, nearly.

COR. Hence it follows that the whole air of a vessel situated as in the proposition will not flow out of it into a void, in any finite time whatever.

XXII. PROP.—To determine the time when the vessel, instead of discharging its air into a void, emits it into air of a less density, that density remaining invariable during the efflux; as may be supposed the case when a vessel holding condensed air emits it into the surrounding atmosphere.

Let the initial density of the air in the vessel be δ , and that of the atmosphere D . Then it is manifest that the expelling force is $P - \frac{PD}{\delta}$ (art. 15.);

and that after the time t it is $\frac{Pd}{\delta} - \frac{PD}{D}$. We have

therefore $\frac{P\delta - PD}{\delta} : \frac{Pd - PD}{D} :: MV : mv :: \delta V^2 : dv^2$;

whence, by reduction, we have $v = V \sqrt{\frac{d(D-D)}{d(D-D)}}$.

From which equation we may learn, that when $d=D$ the motion will be at an end; and that if $\delta=D$ there can be no efflux.

Now, to find the relation between the time and the density, let H , as before, be the height due to the velocity V . Hence the height due to the

velocity of efflux v must be $H \times \frac{\delta(D-D)}{d(D-D)}$, and the

small parcel of air which will flow out in the element of time i will be $adi \sqrt{2gH \frac{\delta(D-D)}{d(D-D)}}$. And

another expression for the same is, as in the preceding article, $-sd$. Making these two values

equal, we soon deduce the fluxionary equation $i =$

$\frac{s\sqrt{\delta-D}}{a\sqrt{2g\delta H}} \times \frac{-d}{\sqrt{d^2-dD}}$. The fluent of this, so corrected that when $t=0$, $d=\delta$, is

$t = \frac{s}{a} \times \sqrt{\frac{\delta-D}{2g\delta H}} \times \text{hyp. log.} \left(\frac{\delta - \frac{1}{2}D + \sqrt{\delta^2 - \delta D}}{\delta - \frac{1}{2}D + \sqrt{\delta^2 - dD}} \right)$.

COR. When d becomes $= D$ the efflux is complete, and the expression for the time will then become

$t = \frac{s}{a} \times \sqrt{\frac{\delta-D}{2g\delta H}} \times \text{hyp. log.} \left(\frac{\delta - \frac{1}{2}D + \sqrt{\delta^2 - \delta D}}{\frac{1}{2}D} \right)$.

XXIII. PROP.—Let the capacities of two vessels containing airs of different densities be A and B ; if they communicate by a tube whose section is a , there will be a current from the vessel containing the denser air into that containing the rarer; it is proposed to find an expression for the time of efflux.

Let P be the elastic force of the air in the vessel A , Q its density, and V its velocity; D being the density of the air in the vessel whose capacity is B . After the time t let the density of the air in A be q , its velocity v , the density of the air in B having become δ . The force expelling from A will then

be $P - \frac{PD}{Q}$ at the first instant, and at the end of the time t it will be $\frac{Pq - P\delta}{Q}$. So that we shall have $\frac{PQ - PD}{Q} : \frac{Pq - P\delta}{Q} :: QV^2 : qv^2$; whence arises

$v = V \sqrt{\frac{Q(q - \delta)}{q(Q - D)}}$; and we see that the motion will cease when $\delta = q$.

Now the capacities of the vessels being A and B respectively, we have for a second equation, including the densities, $AQ + BD = Aq + B\delta$; from which we find $\delta = \frac{A(Q - q) + BD}{B}$. This value of δ

being substituted in the preceding value of v , transforms it to $v = V \sqrt{\frac{Q[B(q - D) - A(Q - q)]}{qB(Q - D)}}$; an equation which gives the relation between the velocity v and the density q .

In order to find the time when the air in A is reduced to the density q , it will be convenient to abridge the work by some substitutions: thus, make $Q(B + A) = M$, $BQ(D + Q) = N$, $BQ - BD = R$, and $\frac{N}{M} = m$. Then, proceeding as in the propositions immediately before this, we obtain the fluxionary equation

$$aqt \sqrt{2gH \cdot \frac{M(q - N)}{Rq}} = \text{flux. of } (AQ - Aq) = -\dot{A}q.$$

This gives $t = \frac{A\sqrt{R}}{a\sqrt{2gMH}} \times \frac{-q}{\sqrt{q^2 - mq}}$; the fluent of which, so corrected that $t = 0$ when $q = Q$, is as below:

$$t = \frac{A}{a} \times \sqrt{\frac{R}{2gMH}} \times \text{hyp. log.} \left(\frac{Q - \frac{1}{2}m + \sqrt{Q^2 - mQ}}{q - \frac{1}{2}m + \sqrt{q^2 - mq}} \right).$$

In a manner not widely different from some of the propositions in this chapter might various other problems relative to the passage of air from one vessel to another be solved: but such problems are not of very frequent use in the common applications of pneumatics to practice, and are therefore not inserted here.

For other researches, &c. connected with pneumatics, see the articles ALTITUDE, ATMOSPHERE, AIR, AIR-PUMP, PUMP, RESISTANCE, WIND, &c. See also Gregory's Mechanics, Vol. I. Book V.

PNEUMATOCELE. (*πνευματοκήλη*; from *πνευμα*, wind, and *κήλη*, a tumour.) Any species of hernia that is distended with flatus.

PNEUMATOLOGY. *s.* (*πνευματολογία*.) The doctrine of spiritual existence.

PNEUMATOPHALUS. (*πνευματοφάλος*; from *πνευμα*, wind, and *ομφαλος*, the navel.) A flatulent, umbilical hernia.

PNEUMATOSIS. (*πνευματωσις*; from *πνευματοω*, to inflate.) Emphysema, or windy swelling. A genus of disease in the class cachexiæ, and order intumescentiæ of Cullen, known by a collection of air in the cellular texture under the skin, rendering it tense, elastic, and crepi-

tating. The species of pneumatosis are: 1. Pneumatosis spontanea, without any manifest cause. 2. Pneumatosis traumatica, from a wound. 3. Pneumatosis venenata, from poisons. 4. Pneumatosis hysterica, with hysteria.

PNEUMONIA. (*πνευμονία*, from *πνευμων*, a lung.) Inflammation of the lungs. A genus of disease in the class pyrexia, and order phlegmasiæ of Cullen; characterised by pyrexia, difficult respiration, cough, and a sense of weight and pain in the thorax. The species of pneumonia, according to the above nosologist, are, 1. Peripneumonia. The pulse not always hard, but sometimes soft: an obtuse pain in the breast; the respiration always difficult; sometimes the patient cannot breathe, unless in an upright posture; the face swelled, and of a livid colour; the cough for the most part moist, frequently bloody. 2. Pleuritis. The pulse hard: a pungent pain in one side, aggravated during the time of inspiration; an uneasiness when lying on one side; a very painful cough, dry in the beginning of the disease, afterwards moist, and frequently bloody. See PLEURITIS.

With respect to pneumonia, the most general cause of this inflammation is the application of cold to the body, which gives a check to the perspiration, and determines a great flow of blood to the lungs. It attacks principally those of a robust constitution and plethoric habit, and occurs most frequently in the winter season and spring of the year; but it may arise in either of the other seasons, when there are sudden vicissitudes from heat to cold.

Other causes, such as violent exertions in singing, speaking, or playing on wind instruments, by producing an increased action of the lungs, have been known to occasion peripneumony. Those who have laboured under a former attack of this complaint are much pre-disposed to returns of it.

The true peripneumony comes on with an obtuse pain in the chest or side, great difficulty of breathing (particularly in a recumbent position, or when lying on the side affected), together with a cough, dryness of the skin, heat, anxiety, and thirst. At the first commencement of the disease the pulse is usually full, strong, hard, and frequent; but in a more advanced stage it is commonly weak, soft, and often irregular. In the beginning the cough is frequently dry and without expectoration; but in some cases it is moist even from the first, and the matter spit up is various both in colour and in consistence, and is often streaked with blood.

If relief is not afforded in time, and the inflammation proceeds with such violence as to endanger suffocation, the vessels of the neck will become turgid and swelled; the face will alter to a purple colour; an effusion of blood will take place into the cellular substance of the lungs, so as to impede the circulation through that organ, and the patient will soon be deprived of life.

If these violent symptoms do not arise, and

the proper means for carrying off the inflammation have either been neglected, or have proved ineffectual, although adopted at an early period of the disease, a suppuration may ensue, which event is to be known by frequent slight shiverings, and an abatement of the pain and sense of fulness in the part, and by the patient not being able to lie on the side which was affected, without experiencing great uneasiness.

When peripneumony proves fatal, it is generally by an effusion of blood taking place into the cellular texture of the lungs, so as to occasion suffocation, which usually happens between the third and seventh day; but it may likewise prove fatal, by terminating either in suppuration or gangrene.

When it terminates by resolution, some very evident evacuation always attends it; such as a great flow of urine, with a copious sediment, diarrhoea, a sweat diffused over the whole body, or a hemorrhage from the nose; but the evacuation which most frequently terminates the complaint, and which does it with the greatest effect, is a free and copious expectoration of thick white or yellow matter slightly streaked with blood, and by this the disease is carried off generally in the course of ten or twelve days.

Our opinion as to the event is to be drawn from the symptoms which are present. A high degree of fever, attended with delirium, great difficulty of breathing, acute pain, and dry cough, denote great danger: on the contrary, an abatement of the febrile symptoms, and of the difficulty of breathing, and pain, taking place on the coming on of a free expectoration, or the happening of any other critical evacuation, promises fair for the recovery of the patient. A termination of the inflammation in suppuration is always to be considered as dangerous.

On dissection, the lungs usually appear inflamed, and there is often found an extravasation, either of blood, or of coagulable lymph in their cellular substance. The same appearances likewise present themselves in the cavity of the thorax and within the pericardium. The pleura, connected with the lungs, is also in an inflamed state, having its surface every where crowded with red vessels. Besides these, abscesses are frequently found in the substance of the lungs, as likewise tubercles and adhesions to the ribs are formed. A quantity of purulent matter is often discovered also in the bronchiae.

PNEUMONICS, in pharmacy, medicines proper to be given in those diseases, in which respiration is affected.

PNEUMORA, in zoology, a genus of the class insecta, order hemiptera. Body ovate, inflated, diaphanous; head inflected, armed with jaws; thorax convex, carinate beneath; wing-cases deflected, membranaceous; legs formed for running. These appear to consist of a mere hollow, inflated membrane; by rubbing together their serrate, or toothed legs they make a shrill kind of noise morning and

evening, and follow a light; they are so nearly allied to the cricket-tribe, that Fabricius has enumerated them under the genus gryllus. Three species; all inhabitants of the Cape, the wing-cases green, immaculate, or spotted with white.

PO, the principal river of Italy, which has its source at Mount Viso in Piedmont, flows through Montferrat, the Milanese, and the Mantuan; thence on the borders of the Parmesan, and a part of the Modenese; and having entered the Ferrarese, it divides at Fichetulolo, and enters the gulf of Venice by four principal mouths. In its course it receives several rivers, and often overflows its banks, as most of those rivers descend from the Alps, and are increased by the melting of the snow. It gives name to a new department of France, including part of Piedmont, of which the capital is Turin.

Po, a river of China, in the province of Kiang-si, which runs into the Poyang-hou, a small distance from Jao-tcheou.

POA, Meadow-grass. In botany, a genus of the class triandria, order digynia. Calyx two-valved, many-flowered; spikelet rounded at the base; corol two-valved, the valves ovate, acuteish, awnless. Sixty-five species, scattered over the globe; of which sixteen are common to our own country: most of them forming an excellent and agreeable food for cattle. The following are the sorts chiefly cultivated:

1. *P. pratensis*. Smooth-stalked meadow-grass. Panicle diffuse; spikelets four-flowered; glumes lanceolate, five-nerved, united by hairs; stipule abbreviated, obtuse.

2. *P. trivialis*. Rough-stalked meadow-grass. Panicle diffuse; spikelets three-flowered; glumes lanceolate, five-nerved, united by fine hairs at the base; stipule elongated.

3. *P. aquatica*. Water-reed grass. Panicle erect, branched, loose; spikelets six-flowered, linear; florets obtuse, seven-nerved. The largest of the British grasses, rising in marshy soils and in waters to the height of five or six feet: most cattle are fond of it; and will often so far plunge into deep stagnant waters for it as to endanger their lives.

For the rest, see **HUSBANDRY**.

To **POACH**. *v. a.* (*oeufs poches*, French.)

1. To boil slightly (*Bacon*). 2. To begin without completing: from the practise of boiling eggs slightly (*Bacon*). 3. (*pocher*, French, to pierce.) To stab; to pierce (*Carew*). 4. (from *pocher*, Fr. a pocket.) To plunder by stealth (*Garth*).

To **POACH**. *v. n.* (from *pocher*, a bag, Fr.)

1. To steal game; to carry off game privately in a bag (*Oldham*). 2. To be damp. A cant word (*Mortimer*).

POACHER. *s.* (from *poach*.) One who steals game (*More*).

POACHINESS. *s.* Marshiness; dampness. A cant word (*Mortimer*).

POACHY. *a.* Damp; marshy (*Mortimer*).

POCHAREL, in ornithology. See **ANAS**.

POCK. *s.* (from *pox*.) A pustule raised by the smallpox.

POCKET. *s.* (pocca, Saxon; *pochet*, Fr.)

1. The small bag inserted into clothes (*Prior*).
2. A pocket is used in trade for a certain quantity: as, a *pocket* of hops.

To POCKET. *v. a.* (*pocheter*, French; from the noun.) 1. To put in the pocket (*Pope*). 2. To POCKET *up*. A proverbial form that denotes the doing or taking any thing clandestinely (*Prior*).

POCKETBOOK. *s.* (*pocket* and *book*.) A paper book carried in the pocket for hasty notes (*Watts*).

POCKETGLASS. *s.* (*pocket* and *glass*.) Portable looking-glass (*Swift*).

POCKHOLE. *s.* (*pock* and *hole*.) Pit or scar made by the smallpox (*Donne*).

POCKINESS. *s.* (from *pocky*.) The state of being pocky.

POCKLINGTON, a town in E. Yorkshire, with a market on Saturday, seated on a stream that runs into the Derwent, 14 miles E. of York, and 194 N. by W. of London.

POCKY. *a.* (from *pox*.) Infected with the pox.

POCO. (Ital.) In music, a term of diminution: as *poco largo*, rather slow, *poco piano*, a little soft.

Poco. (Ital.) Little: as *poco piu lento*, a little slower: *poco piu allegro*, a little quicker.

POCOCKE (Edward), a celebrated orientalist, born at Oxford, 1604. He was educated at Thame school, and Magdalen hall, Oxford, from which he removed to a scholarship at Corpus. Distinguished by his knowledge of classical and oriental literature, he, by the interest of Selden, obtained the place of chaplain to the English factory at Aleppo. He was in 1631 employed by Laud to make a collection of such valuable MSS. and coins as might enrich an university library; and in 1636 he was informed by that liberal patron that he was nominated to fill his newly founded Arabic professorship in Oxford. He returned in consequence from Aleppo, but afterwards went to Constantinople with Greaves, who was going to explore the antiquities of Egypt. He was invited by Laud in 1640 to return, and in his way through Paris, he became acquainted with Grotius, to whom he communicated his intention of translating his book *De veritate christ. religionis*, into Arabic, which the pious author approved. In 1643 he was presented by his college to the rectory of Childrey, Berkshire, where he retired; but he was deprived of his professorship by the republicans. He was in 1647 restored to his salary, and the next year nominated by the king, then a prisoner, professor of Hebrew and canon of Christ-church, an appointment approved by the parliament, but rescinded when he refused to subscribe to the engagement. Though deprived of his canonry, he read lectures, and in 1652 assisted in preparing the edition of the Polyglott bible. The restoration reinstated him in all his offices, but he was neglected among those who had by their services contributed most to the advancement of religion and learning in the kingdom. He died at

Oxford, 1691, aged 87, and was buried in the cathedral. As a scholar and orientalist his abilities were great. His sole ambition was the advancement of oriental literature, to which he devoted himself with assiduous care. His works are Specimen historiae Arabum, 1648, much commended by Prideaux, Ockley, Selden, Reland, and others.—Porta Mosis, or six prefatory discourses of Moses Maimonides—Eutychius' annals—Abul Feraji historia dynastarum, 4to.—Commentaries on Micah, Malachi, Hosea, and Joel, fol.—St. Peter's second epistle, the second and third of John, and that of Jude, translated into Syriac—Letters with several learned men, published by Twells, 2 vols. fol. 1740. His eldest son Edward, rector of Minal, Wilts, published an Arabic work, called Philosophus Autodidactus, sive Epistola Jaafar Ebn Tophail, &c.

POCOCKE (Richard), a divine, related distantly to the celebrated orientalist. He was born 1704, at Southampton, where his father was master of the free school, and he was educated at Corpus Christi, Oxford. He travelled into the East in 1737, and returned in 1742, and in 1744 was made precentor of Waterford. He accompanied as chaplain lord Chesterfield to Ireland, and was appointed by him archdeacon of Dublin, and under another viceroy made bishop of Ossory, 1756. In 1765 he was translated to Elphin and Meath, and died the September of that same year, of a fit of apoplexy. He published a valuable account of his travels, under the title of Observations on Egypt, Palestine, the Holy Land, Syria, Mesopotamia, Cyprus, &c. 3 vols. fol. He also enriched the British museum by the gift of various volumes of MSS.

POCULENT. *a.* (*poculum*, Latin.) Fit for drink.

POD, in botany. See SILIQUE.

PODAGRA. (ποδάγρα; from *πῶς*, the foot, and *αἶσα*, a taking or seizure.) The gout. A genus of disease in the class pyrexia, and order phlegmasia of Cullen; known by pyrexia, pain in the joints, chiefly of the great toe, and especially the hands and feet, returning at intervals: previous to the attack, the functions of the stomach are commonly disturbed. Species: 1. Podagra regularis, the regular gout. 2. Podagra atonica, the atonic gout. 3. Podagra retrograda, the retrocedent gout. 4. Podagra aberrans, misplaced or wandering gout.

PODAGRICAL. *a.* (ποδαγρικός; ποδάγρα.) 1. Afflicted with the gout (*Brown*). 2. Gouty; relating to the gout.

PODALIRIUS, a son of Æsculapius and Epione, was one of the pupils of the Centaur Chiron, under whom he made himself such a master of medicine, that, during the Trojan war, the Greeks invited him to their camp, to stop a pestilence which had baffled the skill of all their physicians. At his return, he was shipwrecked on the coast of Caria, where he fixed his habitation, and built two towns, one of which he called Syrna, from the name of his wife.

PODALYRIA, in botany, a genus of the

class decandria, order monogynia. Calyx somewhat two-lipped, five-cleft; corol papilionaceous, with the wings as long as the standard; legume inflated, many-seeded. Fifteen species; chiefly natives of the Cape.

PO'DDER. s. (from *pod.*) A gatherer of peascods, beans, and other pulse.

PODEX, in anatomy. See **ANUS**.

PODGE. s. A puddle; a plash (*Skinner*).

PODGE, in mastiology. See **DIDELPHIS**.

PODLACHIA, a province of Poland, 88 miles long and 30 broad; bounded on the N. by Prussia, E. by Lithuania, S. by the palatinate of Lublin, and W. by that of Masovia. It is also called the palatinate of Bielsk, from the capital.

PODOLIA, a province in the S.E. part of Poland, wrested from that country by the emperors of Russia, in 1793. The Dniester separates it from Moldavia on the S.W.; and the Bog crosses it from the N. in a S.E. direction. It is divided into the palatinates of Podolia and Bracklaw. Kamienieck is the capital of the former, and Bracklaw of the latter.

PODOPHYLLUM. May-apple. In botany, a genus of the class polyandria, order monogynia. Calyx three-leaved; petals nine; berry one-celled, crowned with the stigma. Two species, creeping plants of North America.

PODOR, a fortress of Africa, on the river Senegal, built by the French. It was ceded to the English in 1763, but afterward taken by the French, and confirmed to them by the peace of 1783. Lon. 14. 20 W. Lat. 17. 1 N.

PODURA. Spring-tail. In zoology, a genus of the class insecta, order aptera. Lip bifid; feelers four, subclavate; eyes two, composed of eight facets; antennae filiform; body scaly; tail forked, bent under the body, and acting as a spring; legs six, formed for running. Thirty-one species, all European insects, chiefly natives of Denmark; twelve common to our own country. They feed on the leaves of various plants; the larve and pupae are six-footed, nimble, and resemble the perfect insect. The following may serve as specimens:

1. **P. villosa.** Rough spring-tail. This is a British insect, and the largest of the tribe known to us. The ground-colour is dark brown, mixed with a shade of yellow, and variegated all over with streaks of black. The abdomen alone is smooth, the head being very much covered with hairs, which are so deciduous, that they stick to the fingers on handling the animal; the antennae consist of four articulations, and are nearly as long as the body. Found under stones.

2. **P. aquatica.** Black, aquatic. Inhabits our own country and Europe. Assembles in troops early in the morning, on the banks of pools and fishponds, appearing like scattered grains of gunpowder to a cursory view; but if closely examined will be found in an almost continual skipping motion.

3. **P. finetaria.** White, terrestrial. Inhabits Europe; found early in the spring in fresh earth.

4. **P. atra.** Frequents melon beds and hot-houses; where, on watering the ground, numbers are seen jumping into the air like atoms: they are the smallest of the *poduræ*, shining brown, and globular.

POE-BIRD, in ornithology, an inhabitant of some of the South Sea Islands, where it is held in great esteem and veneration by the natives. It goes by the name of kogo in New Zealand; but it is better known by that of poe-bird. It is somewhat less than our blackbird. The feathers are of a fine mazarine blue, except those of its neck, which are of a most beautiful silver gray, and two or three short white ones which are on the pinion-joint of the wing. Under its throat hang two little tufts of curled snow-white feathers, called its poies (the Otaheitian word for ear-rings), which occasioned the name of poe-bird being given to it. It is remarkable for the sweetness of its note, as well as the beauty of its plumage. Its flesh is also delicate food.

POECILE, a celebrated portico at Athens, which received its name from the variety of paintings which it contained. It was there that Zeno kept his school, and the stoics also received their lessons there, whence their name, *στωα*, a porch.

POEM. s. (*poema*, Latin; *ποίημα*.) The work of a poet; a metrical composition (*Ben Jonson*).

POENI, a name sometimes given to the Carthaginians.

POESTUM, or **POSIDONIA**, an ancient city of Grecia Magna, now part of the kingdom of Naples. It was founded by one of those colonies from Greece which in the early ages established themselves in Italy; and it flourished before the foundation of Rome itself. It was destroyed by the Goths on the decline of the Roman empire, who in their barbarous zeal for the Christian religion overturned every place of Pagan worship which was exposed to their ravages. Since that time it has been in ruins.

PO'ESY. s. (*poésie*, French; *poësis*, Latin; *ποίησις*.) 1. The art of writing poems (*Ben Jonson*). 2. Poem; metrical composition, poetry (*Shakspeare*). 3. A short conceit engraved on a ring or other thing (*Shakspeare*).

PO'ET. s. (*poète*, French; *poëta*, Lat. *ποιητής*.) An inventor; an author of fiction; a writer of poems; one who writes in measure (*Milton*).

POETASTER. s. (Latin.) A vile petty poet (*Ben Jonson*).

PO'ETESS. s. (from *poet*.) A she poet.

PO'ETICAL. PO'ETIC. a. (*ποιητικός*; *poétique*, Fr.; *poeticus*, Lat.) Expressed in poetry; pertaining to poetry; suitable to poetry (*Hale*).

PO'ETICALLY. ad. With the qualities of poetry; by the fiction of poetry (*Raleigh*).

To POETIZE. v. n. (*poëtiser*, French; from *poet*.) To write like a poet (*Donne*).

PO'ETRESS. s. (from *poetris*, Lat.) A she poet (*Spenser*).

PO'ETRY. s. (*ποιητική*.) 1. Metrical com-

POETRY.

position; the art or practice of writing poems (*Cleaveland*). 2. Poems; poetical pieces (*Shakspeare*).

POETRY, (from the Greek *ποιητρια*, of *ποιω*, *facio*, I make,) is often defined, the art of composing poems, or pieces in verse. According to Aristotle, poetry is *τεχνη μιμητικη*, an imitative art. And Baron Bielfield, in later times, calls poetry the art of expressing our thoughts by fiction.

Neither of these definitions, however, is, in our opinion, sufficiently general. We hope to be able to furnish one that is more satisfactory, but must first present a few preliminary observations.

Poetry is the oldest, the rarest, and the most excellent of the fine arts. It was the first fixed form of language; the earliest perpetuation of thought; it existed before prose in history, before music in melody, and before painting in description. Anterior to the discovery of letters, it was employed to vent the praises of God, to communicate the lessons of wisdom, and to celebrate the achievements of valour; music was invented to accompany, and painting to illustrate it. We have said, that poetry is the *rarest* of the fine arts, and we may appeal to almost any collection of specimens of poetry in proof of our assertion. Thus Southey's Specimens exhibit pieces of more than two hundred writers, among whom there are not twenty whose compositions rise to the dignity of poetry; and of these, perhaps, not more than seven will be known to posterity by their works. The art of constructing easy, elegant, and even spirited verse, may be acquired by any mind of moderate capacity and liberal knowledge; but to frame the lay that quickens the pulse, flushes the cheek, warms the heart, and expands the soul of the reader, playing upon his passions as upon a lyre, and making him feel as if he were conversing with a spirit,—this is the *art of nature herself*, invariably and perpetually pleasing, by a secret undefinable charm, that lives through all her works, and causes the very stones to cry out—

“The hand that made us is divine.”

The power of being a poet is a power from heaven: wherein it consists we know not; but this we do know, that there never existed a poet of the highest order,—and we acknowledge none other to be truly poets,—who either learned his art of one, or taught it to another. It is true that the poet communicates to the bosom of his reader that flame that burns in his own, but the bosom thus enkindled cannot communicate the fire to a third; in the mind of the bard alone that energy of thought which gives birth to poetry is an active principle, in all others it is only a passive feeling. This theory is confirmed by the fact, that though poetical genius is wonderfully aided in its development and display, by learning and taste, yet among the rudest people it is found, like native gold and diamonds, as pure and perfect in substance, though encrusted in baser matter, as among the most enlightened nations; but it is seldomer seen, and in smaller quantities, not being laboriously dug from the mine, purified in the furnace, and polished on the wheel, but only occasionally washed from the mountains, or accidentally discovered among the sands. It is another curious fact, that with the exception of ancient Rome, the noblest works of the muse have been produced in the middle age between gross barbarism and voluptuous refinement, when the human mind yet possessed strong traits of its characteristic

grandeur and simplicity, but, divested of its native fierceness, and chastened by courtesy, felt itself rising in knowledge, worth, and intellectual superiority. The poems of Homer existed long before Greece arrived at its zenith of glory. Dante, Petrarch, and Ariosto, in Italy; Camoens, in Portugal; and Shakspeare, Spenser, and Milton, in England, flourished in ages far inferior to the present in luxury of manners, and refinement of taste: yet their poems, in the respective countries, have not since been equalled, and will probably never be surpassed by their successors.

Poetry is also the most *excellent* of the fine arts. It transcends all other literary composition in harmony, beauty, and splendour of style, imagery, and thought, as well as in the permanency and vivacity of its influence on the mind; for its language and sentiments are so intimately connected that they are remembered together: they are soul and body, that cannot be separated without death,—a death, in which the dissolution of the one causes the disappearance of the other; if the spell of the words be broken, the charm of the idea is lost.

Poetry excels music in the passion and pathos of its movements; for its cadences are ever united with distinct feelings and emotions of the soul, and their association is always clear and comprehensible; whereas music, except when it is allied with poetry, or appeals to memory, is simply a sensual and vague, though innocent, delight, conveying no improvement to the heart, and leaving no abiding impression on the mind.

Once more—Poetry is superior to painting: for poetry is progressive, painting stationary, in its powers of description. Poetry elevates the soul through every rising gradation of thought and feeling, and produces its grandest effects at the last: painting begins precisely where poetry ends, with the climax of the subject, and lets down the mind from the catastrophe, through the details of the story, imperceptibly soothing it from sublime astonishment into tranquil approbation. Poetry tells its own story; painting usually requires an interpreter. Painting is limited to a moment of time, and an eye-glance of space; but it must be confessed that it can make that moment last for years, and render that eye-glance as illustrious as the sun. Poetry is restricted neither to time nor place; resembling the sun itself, it may shine on every quarter of the globe, and endure to the end of ages.

Poetry has a fourth peculiarity, to which we have not yet alluded:—though the most beneficial to the world, it is the most unprofitable to its possessors of all the fine arts. There has scarcely been a period, or a country, in which a poet could live by his skill. It is allowed that great honours and emoluments have been bestowed on some of the tribe; but munificent patronage is yet rarer than transcendent talents:—at the court of Augustus there was only Mæcenâs, but there were many poets. Now, in all ages and nations, musicians and painters of every description have been able to get bread by their labours, and in general they have been dignified and remunerated to the extent of their merits. It must be enough to make a poor poet burst with spleen to read the lives of eminent musicians and painters, and contrast them with those of his more illustrious brethren: while the former have been courted, enriched, and ennobled, by pontiffs and princes, the latter have languished in poverty, and died in despair. Will any man deny that the poems of Milton, as works

POETRY.

of genius, are equal to the pictures of Rubens? Yet the painter's pencil supported him in princely magnificence; the poet's muse could not procure, what even his enemies would have furnished to him gratuitously in a dungeon—bread and water. Poets might be permitted to say, that painting and music may be appreciated in this world, and recompensed by the kings of it; but poetry cannot: its "price is above rubies," and its honours are those which kings cannot confer. (*Eclectic Rev.* iii. 847.)

It is the fate of those maxims which have been thrown out by very eminent writers to be received implicitly by most of their followers, and to be repeated a thousand times, for no other reason than because they once dropped from the pen of a superior genius: one of these is the assertion of Aristotle that "all poetry consists in imitation;" which has been so frequently echoed from author to author, that it would seem a kind of arrogance to controvert it; for almost all the philosophers and critics, who have written upon the subject of poetry, music, and painting, how little soever they may agree in some points, seem of one mind in considering them as arts merely imitative. Yet it must be clear to any one who examines what passes in his own mind, that he is affected by the finest poems, pieces of music, and pictures, upon a principle which, whatever it be, is entirely distinct from imitation. M. le Batteux has attempted to prove that all the fine arts have a relation to this common principle of imitating: but, whatever be said of painting, it is probable that poetry and music had a noble origin; and, if the first language of man was not both poetical and musical, it is certain, at least, that in countries where no kind of imitation seems to be much admired, there are poets and musicians both by nature and by art: as in some Mahometan nations; where sculpture and painting are forbidden by the laws, where dramatic poetry of every sort is wholly unknown, yet where the pleasing arts of expressing the passions in verse, and of enforcing that expression by melody, are cultivated to a degree of enthusiasm. It shall be our endeavour in this article to prove, that though poetry and music have certainly a power of imitating the manners of men, and several objects in nature, yet that their greatest effect is not produced by imitation, but by a very different principle; which must be sought for in the deepest recesses of the human mind.

To state the question properly, we must have a clear notion of what we mean by poetry and music: but we cannot give a precise definition of them till we have made a few previous remarks on their origin, their relation to each other, and their difference.

It seems probable, then, that poetry was originally no more than a strong and animated expression of the human passions, of joy and grief, love and hate, admiration and anger, sometimes pure and unmixed, sometimes variously modified and combined: for if we observe the voice and accents of a person affected by any of the violent passions, we shall perceive something in them very nearly approaching to cadence and measure; which is remarkably the case in the language of a vehement orator, whose talent is chiefly conversant about praise or censure; and we may collect from several passages in Tully, that the fine speakers of old Greece and Rome had a sort of rhythm in their sentences, less regular, but not less melodious, than that of the poets.

If this idea be just, one would suppose that the

most ancient sort of poetry consisted in praising the Deity; for if we conceive a being, created with all his faculties and senses, endued with speech and reason, to open his eyes in a most delightful plain, to view for the first time the serenity of the sky, the splendour of the sun, the verdure of the fields and woods, the glowing colours of the flowers, we can hardly believe it possible that he should refrain from bursting into an ecstasy of joy, and pouring his praises to the Creator of those wonders, and the Author of his happiness. This kind of poetry is used in all nations; but as it is the sublimest of all, when it is applied to its true object, so it has often been perverted to impious purposes by pagans and idolaters. Every one knows that the dramatic poetry of the Europeans took its rise from the same spring, and was no more at first than a song in praise of Bacchus; so that the only species of poetical composition (if we except the epic) which can in any sense be called imitative, was deduced from a natural emotion of the mind, in which imitation could not be at all concerned.

The next source of poetry was, probably, love, or the mutual inclination which naturally subsists between the sexes, and is founded upon personal beauty: hence arose the most agreeable odes, and love-songs, which we admire in the works of the ancient lyric poets, not filled, like our sonnets and madrigals, with the insipid babble of darts and Cupids, but simple, tender, natural; and consisting of such unaffected endearments, and mild complaints,

Teneri sdegni, e plaiede e tranquille
Repulse, e cari vezzi, e liete paci,

as we may suppose to have passed between the first lovers in a state of innocence, before the refinements of society, and the restraints which they introduced, had made the passion of love so fierce and impetuous, as it is said to have been in Dido, and certainly was in Sappho, if we may take her own word for it.

The grief which the first inhabitants of the earth must have felt at the death of their dearest friends and relations gave rise to another species of poetry, which originally, perhaps, consisted of short dirges, and was afterwards lengthened into elegies.

As soon as vice began to prevail in the world, it was natural for the wise and virtuous to express their detestation of it in the strongest manner, and to show their resentment against the corrupters of mankind: hence moral poetry was derived, which, at first, we find was severe and passionate; but was gradually melted down into cool precepts of morality, or exhortations to virtue: we may reasonably conjecture that epic poetry had the same origin, and that the examples of heroes and kings were introduced to illustrate some moral truth, by showing the loveliness and advantages of virtue, or the many misfortunes that flow from vice.

Where there is vice, which is detestable in itself, there must be hate, since "the strongest antipathy in nature," as Mr. Pope asserted in his writings, and proved by his whole life, "subsists between the good and the bad:" now this passion was the source of that poetry which we call satire, very improperly and corruptly, since the satire of the Romans was no more than a moral piece, which they entitled *Satura* or *Satyra*, intimating, that the poem, like "a dish of fruit and corn offered to Ceres," contained a variety and plenty of

P O E T R Y.

fancies and figures; whereas the true invectives of the ancients were called lambi, of which we have several examples in Catullus, and in the Epodes of Horace, who imitated the very measures and manner of Archilochus.

These are the principal sources of poetry; and of music also, as it shall be our endeavour to show: but it is first necessary to say a few words on the nature of sound; a very copious subject, which would require a long dissertation to be accurately discussed. Without entering into a discourse on the vibrations of chords, or the undulations of the air, it will be sufficient for our purpose to observe, that there is a great difference between a common sound and a musical sound, which consists chiefly in this, that the former is simple and entire in itself like a point, while the latter is always accompanied with other sounds, without ceasing to be one; like a circle, which is an entire figure, though it is generated by a multitude of points flowing, at equal distances, round a common centre. These accessory sounds, which are caused by the aliquots of a sonorous body vibrating at once, are called harmonics, and the whole system of modern harmony depends upon them; though it were easy to prove that the system is unnatural, and only made tolerable to the ear by habit: for whenever we strike the perfect accord on a harpsichord or an organ, the harmonics of the third and fifth have also their own harmonics, which are dissonant from the principal note: these horrid dissonances are, indeed, almost overpowered by the natural harmonics of the principal chord, but that does not prove them agreeable. Since nature has given us a delightful harmony of her own, why should we destroy it by the addition of art? It is like thinking

——— to paint the lily,
And add a perfume to the violet.

Now let us conceive that some vehement passion is expressed in strong words, exactly measured, and pronounced, in a common voice, in just cadence, and with proper accents, such an expression of the passion will be genuine poetry; and the famous ode of Sappho is allowed to be so in the strictest sense; but if the same ode, with all its natural accents, were expressed in a musical voice, (that is, in sounds accompanied with their harmonics) if it were sung in due time and measure, in a simple and pleasing tune, that added force to the words without stifling them, it would then be pure and original music; not merely soothing to the ear, but affecting to the heart; not an imitation of nature, but the voice of nature herself. But there is another point in which music must resemble poetry, or it will lose a considerable part of its effect: we all must have observed, that a speaker, agitated with passion, or an actor, who is indeed strictly an imitator, are perpetually changing the tone and pitch of their voice, as the sense of their words varies: it may be worth while to examine how this variation is expressed in music. Every body knows that the musical scale consists of seven notes, above which we find a succession of similar sounds repeated in the same order, and above that other successions, as far as they can be continued by the human voice, or distinguished by the human ear: now each of these seven sounds has no more meaning, when it is heard separately, than a single letter of the alphabet would have: and it is only by their succession, and their relation to one principal sound, that they take any rank in the scale; or differ from each other, except as they are

graver or more acute: but in the regular scale each interval assumes a proper character, and every note stands related to the first or principal one by various proportions. Now a series of sounds relating to one leading note is called a mode, or a tone, and as there are twelve semitones in the scale, each of which may be made in its turn the leader of a mode, it follows that there are twelve modes; and each of them has a peculiar character, arising from the position of the model note, and from some minute difference in the ratios, as of 81 to 80, or a comma; for there are some intervals which cannot easily be rendered on our instruments, yet have a surprising effect in modulation, or in the transitions from one mode to another.

The modes of the ancients are said to have had a wonderful effect over the mind; and Plato, who permits the Dorian in his imaginary republic, on account of its calmness and gravity, excludes the Lydian, because of its languid, tender, and effeminate character: not that any series of mere sounds has a power of raising or soothing the passions, but each of these modes was appropriated to a particular kind of poetry, and a particular instrument; and the chief of them, as the Dorian, Phrygian, Lydian, Ionian, Eolian, Locrian, belonging originally to the nations from which they took their names: thus the Phrygian mode, which was ardent and impetuous, was usually accompanied with trumpets, and the Mixolydian, which, if we believe Aristoxenus, was invented by Sappho, was probably confined to the pathetic and tragic style: that these modes had a relation to poetry, as well as to music, appears from a fragment of Lasus, in which he says, "I sing of Ceres, and her daughter Melibœa, the consort of Pluto, in the Eolian mode, full of gravity;" and Pindar calls one of his Odes an Eolian song. If the Greeks surpassed us in the strength of their modulations, we have an advantage over them in our minor scale, which supplies us with twelve new modes, where the two semitones are removed from their natural position between the third and fourth, the seventh and eighth notes, and placed between the second and third, the fifth and sixth; this change of the semitones, by giving a minor third to the model note, softens the general expression of the mode, and adapts it admirably to subjects of grief and affliction: the minor mode of D is tender; that of C, with three flats plaintive, and that of F, with four, pathetic and mournful to the highest degree, for which reason it was chosen by the excellent Pergolesi in his Stabat Mater. Now these twenty-four modes, artfully interwoven, and changed as often as the sentiment changes, may, it is evident, express all the variations in the voice of a speaker, and give an additional beauty to the accents of a poet. Consistently with the foregoing principles, we may define original and native poetry to be the language of the violent passions, expressed in exact measure, with strong accents and significant words; and true music to be no more than poetry, delivered in a succession of harmonious sounds, so disposed as to please the ear. It is in this view only that we must consider the music of the ancient Greeks, or attempt to account for its amazing effects, which we find related by the gravest historians and philosophers: it was wholly passionate or descriptive, and so closely united to poetry, that it never obstructed, but always increased its influence; whereas our boasted harmony, with all its fine accords and numerous parts, paints nothing, expresses nothing,

P O E T R Y.

says nothing to the heart, and consequently can only give more or less pleasure to one of our senses; and no reasonable man will seriously prefer a transitory pleasure, which must soon end in satiety, or even in disgust, to a delight of the soul, arising from sympathy, and founded on the natural passions, always lively, always interesting, always transporting. The old divisions of music into celestial and earthly, divine and human, active and contemplative, intellectual and oratorical, were founded rather upon metaphors, and chimerical analogies, than upon any real distinctions in nature; but the want of making a distinction between music of mere sounds, and the music of the passions, has been the perpetual source of confusion and contradictions both among the ancients and the moderns: nothing can be more opposite in many points than the systems of Rameau and Tartini, one of whom asserts that melody springs from harmony, and the other deduces harmony from melody; and both are in the right, if the first speaks only of that music which took its rise from "the multiplicity of sounds heard at once in the sonorous body," and the second, of that which rose from "the accents and inflexions of the human voice, animated by the passions:"—"to decide," as Rousseau says, "whether of these two schools ought to have the preference, we need only ask a plain question, Was the voice made for the instruments, or the instruments for the voice?"

In defining what true poetry ought to be, according to our principles, we have described what it really was among the Hebrews, the Greeks and Romans, the Arabs and Persians. The lamentation of David, and his sacred odes or psalms, the song of Solomon, the prophecies of Isaiah, Jeremiah, and the other inspired writers, are truly and strictly poetical; but what did David or Solomon imitate in their divine poems? A man, who is really joyful or afflicted, cannot be said to imitate joy or affliction. The lyric verses of Alcæus, Aleman, and Ibycus, the hymns of Callimachus, the elegy of Moschus on the death of Bion, are all beautiful pieces of poetry; yet Alcæus was no imitator of love, Callimachus was no imitator of religious awe and admiration, Moschus was no imitator of grief at the loss of an amiable friend. Aristotle himself wrote a very poetical elegy on the death of a man whom he had loved; but it would be difficult to say what he imitated in it: "O Virtue! who proposest many labours to the human race, and art still the alluring object of our life; for thy charms, O beautiful goddess! it was always an envied happiness in Greece even to die, and to suffer the most painful, the most afflicting evils: such are the immortal fruits which thou raisest in our minds; fruits more precious than gold, more sweet than the love of parents and soft repose; for thee Hercules the son of Jove, and the twins of Leda, sustained many labours, and by their illustrious actions sought thy favour; for love of thee, Achilles and Ajax descended to the mansion of Pluto; and, through a zeal for thy charms, the Prince of Atarnea also was deprived of the sun's light: therefore shall the Muses, daughters of Memory, render him immortal for his glorious deeds, whenever they sing the god of hospitality, and the honours due to a lasting friendship."

In sir W. Jones's collection of poems there are some Eastern fables, some odes, a panegyric, and an elegy; yet it does not appear to us that there is the least imitation in either of them: Petrarch was certainly too deeply affected with real grief,

and the Persian poet was too sincere a lover, to imitate the passions of others. As to the rest, a fable in verse is no more an imitation than a fable in prose; and if every poetical narrative, which describes the manners, and relates the adventures of men, be called imitative, every romance, and even every history, must be called so likewise; since many poems are only romances, or parts of history, told in regular measure.

What has been said of poetry may with equal force be applied to music, which is poetry dressed to advantage; and even to painting, many sorts of which are poems to the eye, as all poems, merely descriptive, are pictures to the ear: and this way of considering them will set the refinements of modern artists in their true light; for the passions, which were given by nature, never spoke in an unnatural form, and no man, truly affected with love or grief, ever expressed the one in an acrostic, or the other in a fugue: these remains, therefore, of the false taste which prevailed in the dark ages, should be banished from this, which is enlightened with a just one.

It is true, that some kinds of painting are strictly imitative, as that which is solely intended to represent the human figure and countenance; but it will be found, that those pictures have always the greatest effect which represent some passion, as the martyrdom of St. Agnes by Domenichino, and the various representations of the Crucifixion by the finest masters of Italy; and there can be no doubt, but that the famous sacrifice of Iphigenia by Timanthes was affecting to the highest degree; which proves, not that painting cannot be said to imitate, but that its most powerful influence over the mind arises, like that of the other arts, from sympathy.

It is asserted also that descriptive poetry, and descriptive music, as they are called, are strict imitations; but, not to insist that mere description is the meanest part of both arts, if indeed it belongs to them at all, it is clear that words and sounds have no kind of resemblance to visible objects: and what is an imitation, but a resemblance of some other thing? Besides, no unprejudiced hearer will say that he finds the smallest traces of imitation in the numerous fugues, counterfugues, and divisions, which rather disgrace than adorn the modern music: even sounds themselves are imperfectly imitated by harmony, and, if we sometimes hear the murmuring of a brook, or the chirping of birds in a concert, we are generally apprised beforehand of the passages where we may expect them. Some eminent musicians, indeed, have been absurd enough to think of imitating laughter and other noises; but, if they had succeeded, they could not have made amends for their want of taste in attempting it; for such ridiculous imitations must necessarily destroy the spirit and dignity of the finest poems, which they ought to illustrate by a graceful and natural melody. It seems to me, that as those parts of poetry, music, and painting, which relate to the passions, affect by sympathy; so those, which are merely descriptive, act by a kind of substitution; that is, by raising in our minds affections, or sentiments, analogous to those which arise in us when the respective objects in nature are presented to our senses. Let us suppose that a poet, a musician, and a painter, are striving to give their friend, or patron, a pleasure similar to that which he feels at the sight of a beautiful prospect. The first will form an agreeable assemblage of lively images, which he will express in smooth and elegant

P O E T R Y.

verses of a sprightly measure; he will describe the most delightful objects, and will add to the graces of his description a certain delicacy of sentiment, and a spirit of cheerfulness. The musician, who undertakes to set the words of the poet, will select some mode which, on his violin, has the character of mirth and gaiety, as the Eolian, or E flat, which he will change as the sentiment is varied: he will express the words in a simple and agreeable melody, which will not disguise, but embellish them, without aiming at any fugue, or figured harmony: he will use the bass, to mark the modulation more strongly, especially in the changes; and he will place the tenor generally in unison with the bass, to prevent too great a distance between the parts: in the symphony he will, above all things, avoid a double melody, and will apply his variations only to some accessory ideas, which the principal part, that is, the voice, could not easily express: he will not make a number of useless repetitions, because the passions only repeat the same expressions, and dwell upon the same sentiments, while description can only represent a single object by a single sentence. The painter will describe all visible objects more exactly than his rivals, but he will fall short of the other artists in a very material circumstance; namely, that his pencil, which may, indeed, express a simple passion, cannot paint a thought, or draw the shades of sentiment: he will, however, finish his landscape with grace and elegance; his colours will be rich and glowing; his perspective striking; and his figures will be disposed with an agreeable variety, but not with confusion: above all, he will diffuse over his whole piece such a spirit of liveliness and festivity, that the beholder shall be seized with a kind of rapturous delight, and, for a moment, mistake art for nature.

Thus will each artist gain his end, not by imitating the works of nature, but by assuming her power, and causing the same effect upon the imagination which her charms produce to the senses: this must be the chief object of a poet, a musician, and a painter, who know that great effects are not produced by minute details, but by the general spirit of the whole piece, and that a gaudy composition may strike the mind for a short time, but that the beauties of simplicity are both more delightful, and more permanent.

As the passions are differently modified in different men, and as even the various objects in nature affect our minds in various degrees, it is obvious, that there must be a great diversity in the pleasure which we receive from the fine arts, whether that pleasure arises from sympathy or substitution; and that it were a wild notion in artists to think of pleasing every reader, hearer, or beholder; since every man has a particular set of objects, and a particular inclination, which direct him in the choice of his pleasures, and induce him to consider the productions, both of nature and of art, as more or less elegant, in proportion as they give him a greater or smaller degree of delight: this does not at all contradict the opinion of many able writers, that "there is one uniform standard of taste;" since the passions, and, consequently, sympathy, are generally the same in all men, till they are weakened by age, infirmity, or other causes.

If the arguments used in this essay have any weight, it will appear that the finest parts of poetry, music, and painting, are expressive of the passions, and operate on our minds by sympathy; that the inferior parts of them are descriptive of

natural objects, and affect us chiefly by substitution; that the expressions of love, pity, desire, and the tender passions, as well as the descriptions of objects that delight the senses, produce in the arts what we call the beautiful; but that hate, anger, fear, and the terrible passions, as well as objects, which are unpleasant to the senses, are productive of the sublime, when they are aptly expressed or described.

We cannot enlarge here upon the various kinds of oriental poetry: nor can we treat with all the fulness we could wish upon the subject of Greek and Latin, or as they are usually termed, classical poetry. Yet we must remark briefly that while the gems of genius are scattered through oriental compositions with wild luxuriance, they appear in classical poetry displayed in full perfection and beauty. To what causes the pre-eminence of ancient Greece in this part of literature is to be attributed, it would here be futile to conjecture. From the susceptibility of his language, the poet was enabled to exhibit the same idea under a new aspect, and to give to every fluctuation of feeling a permanent expression. If the vivacity of his descriptions fascinated the imagination, his numbers dwelt with no less enchantment on the ear. The length and shortness of syllables in the Greek and Roman languages which constituted their quantities, was determined by rules no less accurate than the notes in music; and on the proper distribution and adjustment of these quantities, the harmony of their metre depended. A stated interval of time was allowed to the pronunciation of every verse. To facilitate the labour of composition, artificial combinations of syllables by the name of feet were invented; and by the number of these, and the quantities included in them, the character of the verse was ascertained.

To these combinations various names were given; the most important were the spondee, composed of two long syllables, and the dactyl, formed by one long and two short syllables. These were solely employed in the construction of the hexameter verse, of which an imitation has been vainly attempted in the English language. The pronunciation of the Greek and Latin languages is, indeed, almost as totally lost to us, as that of the Hebrew; but such is the exquisite mechanism of their metre, that their verses cannot be read without producing a rich and often a melodious intonation, perceptible even to the unlettered ear.

In the happy regions of Greece, it is uncertain what species of poetry was first cultivated. Fables were compositions of great antiquity; the ode formed a part of religious worship; the pastoral must have been introduced in an age sufficiently refined to relish simplicity. The immortal poems of Homer were composed at an early epoch of Grecian literature, and, as is well known, transmitted by oral tradition to a more polished age. Of this extraordinary man so much has been said, that it would appear difficult to say any thing which should not now be trivial or impertinent. This arduous task the perseverance of modern criticism has, however, achieved; and a scholastic sect is now known to exist who would sacrilegiously remove the shrine of Homer from the temple of fame, and abandon to superstitious credulity a name sanctified by the enthusiasm and veneration of preceding ages.

It is pretended that the Iliad and Odyssey were composed at different eras, by various authors; and that these desultory tales of Troy were

POETRY.

at length collocated and edited by some ingenious critic, who might possibly have been distinguished by the appellation of Homer. The novelty, and, perhaps, the extravagance of this hypothesis, have obtained for it partisans among those professed sceptics and segregatists who can perceive no difference between vulgar errors and popular opinions, and whose ambition it is to recede as far as possible from all participation in the sentiments or convictions of other men. It is generally admitted that the excellence in which the supposed Homer stands unrivalled, is the energy of his conceptions, which gives to his personages, his scenes, and his descriptions, a real and individual existence. With such felicity are his characters cast, that no reader of feeling can be at a loss to conceive how Achilles would look, or Nestor speak, or Ulysses act, on any imaginary occasion. The unprejudiced will decide whether such exquisite harmony of design could have been the result of chance, or whether each book had its separate Homer, or whether they were all planned and executed by one.

In lyrical composition, the most popular was the heroic ode. The name of Pindar has descended to us with honour; but the poems which inspired in his compatriots the most exalted enthusiasm are but imperfectly understood by the student, and are almost impracticable to translation. The public recitation of the ode was accompanied both by music and dancing: a circumstance to which its structure was obviously adapted. The two first stanzas, called the strophe and the antistrophe, were of equal length. In the first part the performers approached the altars of their god; in the latter, the dance being inverted, they measured back their steps to their former place, where whilst they sung the epode they stood still. It appears that this form was peculiar to the heroic ode. There were other lyrical compositions of a different cast. Sappho's poems breathe only tender, impassioned sentiment; those of Anacreon, whether amatory or convivial, are equally remote from the sublimity of Pindar, and the melting softness of Sappho. The fervid imagination of Pindar is compared by Horace to the impetuosity of a mountain torrent:

Monte decurrens velut amnis, imbres
Quem super notas aluere ripas,
Fervet, immensusque ruit profundo
Pindarus ore;

Pindar, like some fierce torrent swoln with showers,
Or sudden cataracts of melting snow,
Which from the Alps its headlong deluge pours,
And foams and thunders o'er the vales below,
With desultory fury borne along,
Rolls his impetuous, vast, unfathomable song.

WEST.

The heroic ode is evidently of a dramatic character, and was the primitive source from whence the regular drama was produced. Tragedy originated in the hymns sung in honour of Bacchus; and its name was derived from the goat, which was the victim consecrated to that deity. The invention of dialogue and action belongs to Eschylus; the original ode was preserved in the chorus, which constituted the popular part of the entertainment. The chorus, like the band of a modern orchestra, was composed of several persons who recited in a different manner from the other performers. We learn from Horace that their business was to deduce from the passing scene some lesson of morality, or to inculcate on the spectator some religious precept. The intervention of the

chorus, which is now rejected by the most zealous votaries of Greece, is not more repugnant to our ideas of propriety than many other usages of the ancient stage: the performers appeared in masks; in their recitations they were constantly accompanied by musical instruments, by which the voice was sustained, and the melody of the verse rendered sensible to an immense audience. The rules of the ancient drama were suited to its institution. The unities of time and place were necessary in a performance to which the auxiliary resources of modern machinery were wanting, and from which all the magical illusions of the modern scene were precluded. The tragedies of Euripides and Sophocles were masterpieces in their kind, but would now probably be little relished even by scholars and scholastic enthusiasts.

Comedy, like tragedy, originally consisted of a chorus, which derived its name from the god Comus. The rudiments of the comic art may, perhaps, be detected in the satyrs, a sort of interlude annexed to tragedies, in which the scene was rural, and the personages Satyrs, or sylvan deities. In the plays of Aristophanes, living characters were introduced, and Socrates beheld himself ridiculed on the stage. This abuse a better taste corrected; and the comedies of Menander, which were imitated by Terence, exhibited only interesting pictures of domestic life. The chorus at first appendant on comedy, was gradually changed into the prologue, a personage who carefully apprized the spectators of all they were to see on the stage.

The Roman writers were modelled on those of Greece, and it was long before they attempted to emulate their masters; yet Ennius, one of their elder poets, produced the satire, a species of miscellaneous poetry purely Roman, which was destined to receive perfection from Horace. With equal originality, Lucretius wrote his metaphysical systems of his age; but it was not till the era of Augustus that the bards of Latium established their equality with those of Greece. It was then that Horace, not satisfied with having transplanted all the lyric beauties to his odes, opened a rich vein of satiric poetry; and Virgil, having equalled Theocritus, without temerity aspired to emulate Homer. In the *Æneid* it may be acknowledged that he sometimes fell short of his master. His characters possess not the same features, durability and grandeur; nor are his scenes equally animated and dramatic. To atone for these defects, he unites every charm that gives interest to narrative or lends enchantment to description; occasionally he rises to the sublime, but the beautiful is his natural element; he can excite terror, but he is more prone to inspire tenderness and pity. In the delicate touches of nature and pathos, he seems to have grown enamoured of his subject, and to have lingered affectionately on the endearing scenes and charities of domestic life. The four first books of the *Æneid* contain a tale so sweetly told, that was it transferred to a rude language, totally unsusceptible of its literary graces, it would still be read and remembered by all who had capacities for sympathy and tenderness.

In the *Georgics*, Virgil has left a model of didactic composition, enabled by a strain of philosophical sentiment, pure, graceful, and persuasive. Ovid, whose talents were not less versatile than those of his contemporaries, adorned the fables of mythology with description, and illustrated in his epistles almost every romantic story of antiquity. The style of his elegies is not un-

POETRY.

like that of his epistles: he paints to the eye, but he has often too much wit and fancy to touch the heart.

Tibullus has exceeded every other elegiac writer in simplicity and tenderness. Lucan and Statius were also epic poets, but they are seldom quoted, and not often read. Lucan possessed a genius of an exalted order; but his subject was peculiarly unfortunate, and his beauties are now neglected because they are found in scenes repulsive to the imagination, and uncongenial with the feelings.

Among the last poets of Rome, appeared Juvenal and Persius, of whom the former was one of the most original writers she had produced. He professes to exhibit a picture of his times; and there is in his manner an undissembled and almost a holy fervour that atones for his occasional ruggedness and asperity.

Origin of modern poetry.—The Gothic nations who over-ran Rome, though ignorant of the polite arts, were not insensible to the charms of poetry. Their bards were no less venerated than their priests; and whatever instruction they received, whatever knowledge they possessed, was communicated in metre, and probably in rhyme.

In the age of Charlemagne, the minstrels of Provence, or, as they were called, the troubadours, introduced the metrical tales or ballads, which, from the dialect in which they were written, acquired the name of romances. Their poems were all composed in rhyme; but whether this practice was borrowed from the Arabs or the Goths is uncertain. The Italian language, which of all the corrupt dialects introduced by the barbarians, assimilated most with the Roman, soon acquired a tincture of elegance. In the middle ages Dante wrote; Ariosto followed; and Petrarch, the enthusiastic votary of classical genius, appeared among the first founders of modern literature. The passion for allegory, so long the characteristic of the Italian school, was by Chaucer rendered as prevalent in England as it had previously been on the continent. During several ages, Italy continued to be the Poets' Land of Europe; and in that interval was produced the Jerusalem Delivered, a poem not unworthy of a Roman bard, or an Augustan age.

In Spain, poetry was early cultivated, but with little attention to classical taste. In France, it emerged not from barbarism till the reign of Francis the First, and arrived at its ultimate point of perfection in the era of Louis the Fourteenth. La Fontaine and Boileau, Corneille and Racine, had then lived, and produced works destined to immortalize their names. Unfortunately for French poets, criticism was then almost coeval with poetry; and a pedantic attention to rules was soon permitted to repress the native energies of genius. The modern drama, it is well known, originated in the mysteries; a sort of religious farce, imported from the East. To the mysteries succeeded allegorical plays, called moralities: these produced the mask, which became the favourite amusement of the court in the time of Charles the First, and is redeemed from opprobrium and oblivion by Milton's *Comus*. Gondibert, written by lord Sackville, was the first tragedy represented on an English stage. Till the commencement of the eighteenth century, the German language was almost a stranger to poetry. Klopstock invented hexameter verse, in which the mechanism of classical numbers is rather perceived than felt by the reader. From that era, Germany has been more productive of books than

all the rest of Europe; and during this period, many fine writers have arisen of real and original genius: but the literary commerce of the country is chiefly supported by translation; the Germans having arrived at no less distinction as the general translators, than did their neighbours the Dutch as the carriers, of Europe.

Of English versification.—In the English language, versification depends not on the quantities, or the length and shortness of the syllables: but on the modulation of the accents, and the disposition of the pauses; to which is generally added the recurrence of rhyme. The heroic verse consists of ten syllables; its harmony is produced by a certain proportionate distribution of accented and unaccented syllables; and its specific character, whether lively or solemn, soft or slow, is determined by their order and arrangement. When unaccented and accented syllables are regularly alternated, it is called the iambic verse; as,

"A shepherd's boy, he seeks no higher name, |
Led forth his flock beside the silver Thame."

When this order is inverted, and the unaccented is preceded by the accented syllable, it is called a trochaic verse; as,

"Ambition first sprung from the bléss abode." |
"Take, holy earth, all that my soul holds dear."

The frequent intervention of the trochaic is apt to produce harshness. The monotony which it might be expected should result from a succession of iambic lines, is obviated by the freedom with which the pause is transferred from one syllable to another; a freedom which constitutes the charm, and produces all the variety, of English verse. The pause or cesura is that interval of suspension which must naturally arise in every verse, the position of which the English poet is allowed to change and diversify at pleasure. When the pause falls on the fourth syllable, the strain is smooth and airy; as,

"Soft is the strain | when Zephyr gently blows,
And the smooth stream | in smoother number flows."

When it falls on the second it is commonly accelerated; as,

"Not so | when swift Camilla scours the plain."

Occasionally the pause dwells on the first, second, or penultimate syllable:

"O friend! | may each domestic bliss be thine:
Be no unpleasing melancholy | mine.
Me | let the tender office long engage,
To rock the cradle of declining age."

A second pause is sometimes happily introduced:

"O ever beauteous | ever lovely | tell,
Is it in heaven a crime to love too well?"

In the following examples, the first passage has all the spirit and energy of the ode; the second, the slow and plaintive melody of the elegiac strain:

"Come then, my friend, my genius, come along,
O master of the poet and the song!
And while the muse now stoops, | and now ascends,
To man's low passions, | or their glorious ends,
Teach me, like thee, | in various nature wise,
To fall with dignity, | with temper rise;
Form'd by thy converse, | happily to steer
From grave to gay, | from lively to severe;

POETRY.

Correct with spirit, | eloquent with ease,
Intent to reason, | or polite to please."

"In these deep solitudes, | and awful cells,
Where heavenly pensive contemplation | dwells,
And ever-musing melancholy reigns."

The heroic verse is often diversified by the intervention of an Alexandrine line of twelve syllables, which is liberally used by Dryden: its abuse is pointedly censured by Pope;

"A needless Alexandrine ends the song,
Which, like a wounded snake, drags its slow
length along."

It forms a noble termination:

"Teach me to love and to forgive;
Exact my own defects to scan,
What others are to feel, and know myself a
man."

Triplets often occur in heroic verse; a practice to which Dryden was strongly addicted, but which is now generally avoided by correct writers.

The stanza of nine lines, in imitation of the Italian, was introduced by Spenser. Of this verse, which, if not impracticable, was at least repugnant, to the English language, the following extract is a favourable specimen:

"A gentle knight was pricking on the plaine,
Yclad in mightie arms, and silver shield,
Wherein old dintes of deep woundes did remain,
The cruel marks of many a bloody field;
Yet armes till that time did he never wield.
His angry steed did chide his foaming bitt,
As much disdainig to the curb to yield:
A jolly knight he seem'd, and faire did sit,
As one for knightly guests and fierce encounters
fitt."

A stanza more polished in its structure is adopted by Mr. Sotheby in his admirable translation of Wieland's *Oberon*. The following passage describes Rezia's first interview with the Hermit:

"Rezia, at once entranced in holy bliss,
Aw'd by his look, that beams celestial grace,
Bows as before the genius of the place,
And prints his wrinkled hand with pious kiss.
Touched by his gracious mien or friendly air,
His beard that swept his breast with silver hair,
Her soul this stranger as her sire reveres;
A second look has banish'd all her fears:
Each reads the other's heart, nor finds a stranger
there."

The most popular stanza is that appropriate to the ballad, which is composed of four lines with interchanging rhymes. Such is the measure of Goldsmith's beautiful tale of *Edwin and Angelina*:

"Turn, gentle hermit of the dale,
And guide my lonely way,
To where yon taper cheers the vale
With hospitable ray."

And such, with the remission of rhyme in the first and third lines, is the measure of Chevy Chase:

"God save the king, and bless the land,
In plenty, joy, and peace;
And grant henceforth that foul debate
'Twixt noblemen may cease!"

The elegiac stanza consists of four alternately responsive lines of ten syllables each: it is well adapted to short poems; but in compositions of any length, its slow monotonous cadence becomes oppressive to the ear. In the celebrated elegy of

Gray, its defects, however, are all concealed by a profusion of poetical beauties; and by the graceful muse of Hammond its fetters are rendered elegant and ornamental:

"Why should the lover quit his pleasing home,
In search of danger on some foreign ground?
Or from his weeping fair ungrateful roam,
And risk in every stroke a double wound?
Ah! better far, beneath the spreading shade,
With cheerful friends to drain the sprightly bowl,
To sing the beauties of my darling maid,
And on the sweet idea feast my soul."

The common anapestic verse, of eleven and twelve syllables, in which the accent falls on every third syllable, has generally been appropriated to humorous subjects: when formed into the stanza, it assumes a different character. In the noble war-song of Burns it is however a strain truly sublime; and in the following passage of Beattie flows with equal sweetness and pathos:

"'Tis night, and the landscape is lovely no
more:

I mourn, but, ye woodlands, I mourn not for you;
For morn is approaching, your charms to restore,
Perfum'd with fresh fragrance, and glittering with
dew.

Nor yet for the ravage of winter I mourn;
Kind nature the embryo blossom will save:
But when shall spring visit the mouldering urn?
Oh! when shall it dawn on the night of the
grave?"

This stanza is, from the intractable nature of the anapestic measure, of difficult execution. In that employed by Cowper in the following instance, constructed on similar principles, the syllables are less numerous, and the cadence is in general more harmonious:

"I am monarch of all I survey,
My right there is none to dispute;
From the centre, all round to the sea,
I am lord of the fowl and the brute.
O Solitude! where are the charms
That sages have seen in thy face?
Better dwell in the midst of alarms
Than reign in this desolate place."

The occurrence of double rhymes is neither very frequent nor very easy in English verse; they are chiefly employed in songs, and are seldom admitted in the higher order of lyrical composition. The following passage from Dryden's ode on *St. Cecilia's day* affords the most happy example of this kind of verse in our language:

"Softly sweet in Lydian measures,
Soon he sooth'd his soul to pleasures;
War, he sung, is toil and trouble,
Honour but an empty bubble;
Never ending, still beginning,
Fighting still and still destroying:
If the world be worth thy winning,
Think, oh! think it worth enjoying."

The simplest and most fluent of all verse is the couplet of eight syllables. In this measure Milton has written his two exquisite poems, the *Allegro* and *Penseroso*:

"And may at length my weary age
Find out the peaceful hermitage,
The hairy gown and mossy cell,
Where I may sit, and rightly spell
Of every star that heaven doth shew,
And every herb that sips the dew,

POETRY.

Till old experience do attain
To something like prophetic strain?"

Pope and Gray are generally considered as the most correct writers of rhyme; and Dryden, who knew the affluence of the English language, has in his own compositions exhibited all its various capacities of harmony and versification.

Blank verse is composed of lines of ten syllables each, which flow into each other without the intervention of rhymes; its metrical principle resides in its pauses, which should be so judiciously spread as never to suffer the accompaniment of rhyme to be missed. Of the few poets who have attempted this species of composition, Milton first, and after him, Thomson, Armstrong, Aken-side, and Cowper, are pre-eminent. The amplitude of Milton's verse is unequalled: it dilates with the author's thought, it harmonizes with the reader's sentiment, and its varied cadence alternately rolls with majesty, or falls in a mellifluous strain of melody on the unwearied and unsated ear. The principle of this exquisite mechanism has been lately referred by a judicious critic (the Rev. M. Crowe, in his Lectures at the Royal Institution), to Milton's bold practice of distributing in separate lines words so nearly connected (such as the preposition governing the noun, and the pronoun attached to the verb) as almost to appear indivisible. That this practice, which Mr. Crowe calls breaking the natural joint of the sentence, is favourable to the freedom of blank verse, cannot be disputed; but it may be questioned whether the poet was himself conscious of the mechanism which he employed, or was directed by any other principle than his own acute sensibility to harmony. The following short extracts may illustrate the difference of style perceptible in the various writers of blank verse:

"Of man's first disobedience, and the fruit
Of that forbidden tree whose mortal taste
Brought death into the world, and all our woe,
With loss of Eden, till one greater man
Restore us, and regain the blissful seat,
Sing, heavenly muse that on the secret top
Of Oreb, or of Sinai, didst inspire
The shepherd who first taught the chosen seed,
In the beginning how the heavens and earth
Rose out of chaos; or if Sion hill
Delight thee more, and Siloa's brook that flowed
Fast by the oracle of God, I thence
Invoke thy aid to my adventurous song;
That with no middle flight intends to soar
Above the Aonian mount, while it pursues
Things unattempted yet in prose or rhyme."

MILTON.

"He comes! he comes! in every breeze, the
power
Of philosophic melancholy comes:
His near approach the sudden-starting tear,
The glowing cheek, the mild dejected air,
The soften'd feature, and the beating heart,
Pierc'd deep with many a virtuous pang, declare.
O'er all the soul his sacred influence breathes,
Inflames imagination, through the breast
Infuses every tenderness, and far
Beyond dim earth exalts the swelling thought."

THOMSON.

"From heaven my strains begin; from heaven
descends
The flame of genius to the chosen heart,
And beauty with poetic wonder join'd
And inspiration. Ere the rising sun
Shone o'er the deep, or mid the vault of night
The moon her silver lamp suspended; ere

The vales with spring were watered, or with groves
Of oak, or pine, the ancient hills were crown'd;
Then the great Spirit whom his works adore,
Within his own deep essence view'd the forms,
The forms eternal of created things:
The radiant sun, the moon's nocturnal lamp,
The mountains and the streams, the ample stores
Of earth, of heaven, of nature. From the first,
On that full scene his love divine he fix'd,
His admiration; till in time complete,
What he admired and lov'd, his vital power
Unfolded into being."

AKENSIDE.

"O ye whose souls relentless love has tam'd
To soft distress, or friend untimely fallen!
Court not the luxury of tender thought;
Nor deem it impious to forget those pains
That hurt the living, nought avail the dead.
Go, soft enthusiast, quit the cypress groves;
Nor to the rivulet's lonely moanings tune
Your sad complaint. Go, seek the cheerful
haunts
Of men, and mingle with the bustling crowd;
Lay schemes for wealth, or power, or fame—the
wish
Of nobler minds, and push them night and day;
Or join the caravan, in quest of scenes
New to your eyes, and shifting every hour,
Beyond the Alps, beyond the Appenines."

ARMSTRONG.

"O winter, ruler of the inverted year,
Thy scattered hair, with sleet like ashes fill'd,
Thy breath congeal'd upon thy lips, thy cheeks
Fring'd with a beard made white with other
snows
Than those of age, thy forehead wrapt in clouds,
A leafless branch thy sceptre, and thy throne
A sliding car indebted to no wheels,
But urg'd by storms along its slippery way!
I love thee; all unlovely as thou seem'st,
And dreaded as thou art. Thou hold'st the sun
A prisoner in the yet undawning east,
Short'ning his journey between morn and noon,
And hurrying him, impatient of his stay,
Down to the rosy west; but kindly still
Compensating his loss with added hours
Of social converse, and instructive ease."

COWPER.

The defect of Young's blank verse is, that the sense commonly closes with the line, and that it has too much of the systematical uniformity, without the musical varieties, of rhyme. Whether rhyme or blank verse is entitled to pre-eminence, is a question which must ultimately be determined by individual taste. In the choice of his measure, the poet must obviously be influenced by the nature of his subject; and rhyme or blank verse will alternately obtain his preference. In all the gay and airy excursions of fancy, or the lighter touches of feeling, he will find in rhyme an auxiliary equally pleasing and important. To such compositions as require a measure of spirited and vivacious movement, rhyme is an indispensable appendage. To satire it adds poignancy, to humour it gives elegance; it imparts renovation to old ideas, and lends attraction to trivial sentiments; it renders familiar illustration graceful, and plain sense eloquent. In all but the Alpine regions of poetry, rhyme is a fence no less useful than ornamental, enriching and enlivening every object. In the Allegro and Penseroso, even Milton conceived it no dereliction of poetical freedom to have pursued the path traced out by his predecessors: but in his *Paradise Lost*,

when "he soared beyond the visible diurnal sphere," his deviation into blank verse was as judicious as fortunate; because his subject was then too sublime, his conceptions too gigantic, for the narrow limits and demarcations of rhyme. Wherever much originality of thought exists, this metrical charm is unnecessary; and where imagination reigns in wild luxuriance, it is impertinent. In some of his juvenile poems, Milton appears to have been incumbered with the dignity of his thoughts; and Shakspeare, perplexed by the richness and variety of his combinations, is apt to become affected when he quits blank verse. Attempts have been made to enlarge the limits of blank verse, by the introduction of various measures analogous to those employed in rhyme: but to all these efforts the genius of the language discovers an invincible repugnance; vainly are varieties presented to the eye, which are imperceptible to the mind, and untasted by the ear. All rhymeless numbers either flow into good blank verse, or form lines harsh and untractable; a succession of abrupt sounds and mutilated sentences, which by no art of typography, by no imposition of nomenclature, can be made to constitute any metre at all.

See farther the articles ELEGY, LYRIC, PASTORAL, SONNET, &c.

POGGE, in ichthyology. See COTTUS.

POGGIO (Bracciolini), a man of great parts and learning, who contributed much to the revival of knowledge in Europe, was born at Terranuova, in the territories of Florence, in 1380. His first public employment was that of writer of the apostolic letters, which he held 10 years, and was then made apostolic secretary, in which capacity he officiated 40 years, under seven popes. In 1453, when he was 72 years of age, he accepted the employment of secretary to the republic of Florence, to which place he removed, and died in 1459. He visited several countries, and searched many monasteries to recover ancient authors, numbers of which he brought to light: his own works consist of moral pieces, orations, letters, and a History of Florence from 1350 to 1455, which is the most considerable of them. His life has been lately published, in a 4to. volume, by Mr. Shepherd.

POGGY, an island in the Indian ocean, on the W. side of the island of Sumatra, and separated from the N. end of that of Nassau by a narrow channel. It is triangular, and about 20 miles in length. Lon. 99. 30 E. Lat. 2. 20 S.

POIGNANCY. *s.* (from *poignant*.) 1. The power of stimulating the palate; sharpness (*Swift*). 2. The power of irritation; asperity.

POIGNANT. *a.* (*poignant*, French.) 1. Sharp; stimulating the palate (*Locke*). 2. Severe; piercing; painful (*South*). 3. Irritating; satirical; keen.

POINCIANA. Barbadoes flower-fence. In botany, a genus of the class decandria, order monogynia. Calyx pentaphyllous; petals five, the uppermost largest; stamens long, all fertile; pericarp, a legume. One species only; *P. pulcherima*, a native of both the Indies. This rises with a straight stalk to the height of

ten or twelve feet; the branches terminate in loose spikes of flowers, sometimes pyramidal, and sometimes umbellate. The first stalk of each flower is about three inches long: the flower itself consists of five petals, roundish at the top, but contracted to narrow tails at the base. They are patent, and beautifully variegated with deep red, orange or yellow, often spotted with green; and emit a very agreeable odour. On the fading of the flower, the legume or pod into which the germ expands is about three inches long, divided into three or four cells, by transverse partitions, each including a single seed, flattish and irregular. The plant is propagated by seeds; but is too tender to flourish beyond the protection of a bark-stove.

POINT. *s.* (*point*, French.) 1. The sharp end of any thing (*Temple*). 2. A string with a tag (*Shakspeare*). 3. Headland; promontory (*Addison*). 4. A string of an epigram (*Dryden*). 5. An indivisible part of space (*Locke*). 6. An indivisible part of time; a moment, 7. A small space (*Prior*). 8. Punctilio; nicety (*Milton*). 9. Part required of time or space; critical moment; exact place (*Atterbury*). 10. Degree; state (*Sidney*). 11. Note of distinction in writing; a stop. 12. A spot; a part of a surface divided by spots; the ace or size *point*. 13. One of the degrees into which the circumference of the horizon, and the mariner's compass, is divided (*Bacon*). 14. Particular place to which any thing is directed (*Brown*). 15. Particular; particular mode (*Shakspeare*). 16. An aim; the act of aiming or striking (*Shakspeare*). 17. The particular thing required; the aim the thing *points* at (*Roscommon*). 18. Particular instance (*Temple*). 19. A single position; a single assertion; single part of a complicated question; a single part of any whole (*Baker*). 20. A note; a tune (*Shakspeare*). 21. *Pointblank*; directly: as, *an arrow is shot to the pointblank, or white mark* (*Shakspeare*). 22. *Point de vise*; exact or exactly in the point of view (*Bacon*).

POINT, in music, a mark or note anciently used to distinguish the tones or sounds: hence we still call it simple counter-point, when a note of the lower part answers exactly to that of an upper; and figurative counter-point, when any note is syncopeated, and one of the parts makes several notes or inflexions of the voice, while the other holds on one. We still use a point, to raise the value of a note, and prolong its time by one half, *e. g.* a point added to a semibreve instead of two minims, makes it equal to three; and so of the other notes. See the article TIME.

POINT, in astronomy, a term applied to certain points or places marked in the heavens, and distinguished by proper epithets. The four grand points or divisions of the horizon, viz. the east, west, north, and south, are called the cardinal points. The zenith and nadir are the vertical points; the points wherein the orbits of the planets cut the plane of the ecliptic are called the nodes: the points wherein the equator and ecliptic intersect are called the equinoctial

points; particularly, that whence the sun ascends towards the north pole, is called the vernal point; and that by which he descends to the south pole, the autumnal point. The points of the ecliptic, where the sun's ascent above the equator, and descent below it, terminate, are called the solstitial point; particularly the former of them, the estival or summer-point; the latter, the brumal or winter-point.

POINT, in the manufactories, is a general term, used for all kinds of laces wrought with the needle; such are the point de Venice, point de France, point de Genoa, &c., which are distinguished by the particular economy and arrangement of their points.—Point is sometimes used for lace woven with bobbins: as English point, point de Malines, point d'Havre, &c.

To POINT. v. a. (from the noun.) 1. To sharpen; to forge or grind to a point. 2. To direct toward an object, by way of forcing it on the notice (*Milton*). 3. To direct the eye or notice (*Pope*). 4. To show as by directing the finger (*Addison*). 5. (*pointer*, French.) To direct toward a place: *he pointed his gun*. 6. To distinguish by stops or points.

To POINT. v. n. 1. To note with the finger; to force on the notice, by directing the finger toward it (*Ray*). 2. To distinguish words or sentences by points (*Forbes*). 3. To indicate as dogs do to sportsmen (*Gay*). 4. To show distinctly (*Swift*).

POINTAL, in botany. See **PISTIL**.

POINTED. a. or participle. (from *point*.) 1. Sharp; having a sharp point or pique (*Dryden*). 2. Epigrammatical; abounding in conceits (*Pope*).

POINTEDLY. ad. (from *pointed*.) In a pointed manner (*Dryden*).

POINTEDNESS. s. (from *pointed*.) 1. Sharpness; pickiness with asperity (*Ben Jonson*). 2. Epigrammatical smartness (*Dryden*).

POINTEL. s. Any thing on a point (*Derham*).

POINTER. s. (from *point*.) Any thing that points (*Watts*).

POINTER, a variety of the domestic dog (see **CANIS**) well known to contribute very largely to the pleasures and pursuits of the sportsman. The breed, on account of its general utility, has been so perpetually crossed, re-crossed, bred in, and bred out, of late years, that it is now to be found of all sizes, and all qualifications; from the slow, short-headed, heavy-shouldered remains of the original Spanish pointer, that will tire in half a day's work, to the cross of in and in with a fox-hound, which is never known to tire; many of these having speed enough to catch a leveret three parts grown, when it jumps up before them. Pointers, forty or fifty years since, were hardly ever seen but entirely white, or variegated with liver-coloured spots; except the then duke of Kingston's black and white, which were considered superior to every breed in the kingdom, and sold for most extravagant sums after his

death. They are now, from the constantly increasing attachment to field sports, to be seen of every description, from pure white, and a flea-bit blue or grey, to a universal liver-colour, and a perfect black. In a choice of pointers for general use, that is for every species of game, the extremes in size, as well as in speed, are better avoided: overgrown, heavy dogs, soon get weary in the hot and early part of the season: and the very small sorts have their inconveniences in hunting in very high turnips, heath, broom-fields, &c.

As some advantages have been obtained by the various crosses, both in respect to speed, and ability to endure fatigue, so something has been sacrificed on the score of patience and keenness of smell. Pointers are never considered complete, unless they are perfectly staunch to bird, dog, and gun; which implies, first, standing singly to a bird or a covey; secondly, to backing (or pointing instantaneously likewise) the moment they perceive another dog stand; and lastly, not to stir from their point, upon the firing of any gun in company, provided the game is neither sprung nor started at which the original point was made.

The art of breaking pointers for the field was, twenty or thirty years since, looked upon as a very mysterious and difficult piece of business; many (called dog-breakers) deriving a subsistence from the employment: the charm, however, has been long since dispelled, and the process is known to be so exceedingly simple, that a tolerable well-bred pointer puppy may have the foundation of all his future perfections inculcated in the very kitchen or parlour of his master, before he is taken into the field. The system indeed is so easy that it may be applied to two or three brace together in a large room, or small yard, with no other assistance than the phrases "hie-on!" "to-ho!" "take heed!" and "have a care!" a small field whip being in hand to impress attention; when although meat be tossed before them in every direction, not a dog will stir till the signal of "hie-on" is heard, which they eagerly obey; but are as instantly stopped at the very moment of seizing their meat, by either of the other phrases. Young dogs, having thus imbibed the principles upon which they are to act, have nature, and their instinctive impulse, to point out their practice when brought into the field: few are seen who hunt too little, the larger part are inclined to range too widely, and then it is that the cool and steady patience of the experienced sportsman becomes necessary to check their impetuosity. Juvenile gunners frequently spoil young dogs, by keeping them under as little restraint as they wish to be kept under themselves; and too often let them break away out of all reasonable distance, till they acquire a habit of inattention and disobedience, of which some are with very great difficulty, if ever, divested.

When brought into the field, they should be taught to traverse every yard of the ground, (in proper lengths, and at proper distances,) so that

none be left unbeaten ; and this should be done with as few words, and as little noise, as possible. Short verbal signals, low vibrative whistles, and the motion of the hand to the right or left, are all that is necessary ; more does mischief : one steady shot-man of this description, with a brace of pointers obedient to command, and staunch to dog and gun, will kill more game in any country, than a noisy crew with three or four brace of dogs before them. No young pointers should be permitted to deviate from the proper rule of quartering the ground before them ; that is, they should be restricted to cover a line of fourscore yards transversely in the front of their master, taking forty yards to his right, and re-passing him, taking the same distance to the left ; and in such proportions as not to let their crossings and re-crossings be more than five-and-twenty or thirty yards from each other. If a brace of pointers be in the field, they should alternately cross the same beat, by meeting and passing each other ; but never beat the same way in a parallel direction.

Those who wish pointers to bring the game when killed will find it very easy of attainment, by teaching them to fetch and carry before they take the field ; it is an amusement they are much delighted with, and never forget : it has, however, one chance of inconvenience annexed to the experiment, for they may become hard-mouthed, and take to breaking both flesh and feather, which will be found extremely troublesome. It is a practice with some persons to hunt their pointers in coverts, with bells about their necks, both in cock and pheasant shooting ; those who do it, however, hold their pointers (at least their excellence) in very slender estimation, as it invariably reduces their speed ; renders them slow, tardy, undisciplined, and inclined to hang and puzzle, by constantly drawing upon the foot of the pheasant, or upon a hare in covert, when one happens to start before them. Previous to the beginning of the season, that is, a fortnight before the commencement, each dog should have two doses of physic about four days apart ; after which proper attention should be paid to the provision, which should be of a sweet and healthy kind, to preserve as much as possible their faculties in full perfection. From the hardness and heat of the ground in the first weeks of September, it sometimes happens, that the feet become lacerated, inflamed, and exceedingly sore ; when this is observed, a plentiful washing, with warm gruel and a sponge, will afford considerable relief ; in an hour or two after which, the application of some weak salt and water, or cold white-wine vinegar, will harden the surface, and probably prevent a repetition. See TRAINING.

POINTING. See PUNCTUATION.

POINTS, in electricity. See ELECTRICITY.

POINTINGSTOCK. *s.* (*pointing* and *stock*.) Something made the object of ridicule (*Shakspeare*).

POINTLESS. *a.* (from *point*.) Blunt ; not sharp ; obtuse (*Dryden*).

POISERS, in entomology, two pedicelled heads placed one under each wing of such insects as have only two.

POISON. (*venenum*, Lat.) Any substance which when applied to the animal frame, externally or internally, injures or destroys it by exciting morbid action. This is an extensive definition ; but the diversified nature of the substances that fall within the meaning of the term, and the multifarious mode of their action, prevent us from being able to limit it within narrow bounds. They may be contemplated under the four classes of animal, vegetable, mineral, and halituous or gaseous poisons.

Preliminarily, however, we will observe, that most of the substances properly called poisonous are only so in certain doses ; for below this point in the general scale, many of them form the most active and consequently the most valuable medicines of the dispensary. There are nevertheless some poisons which are deleterious and even fatal in the smallest quantities imaginable, and which are hence never administered medicinally ; such are those of hydrophobia and the plague. There are other poisons, again, which are innocent when taken into the stomach, but which prove deleterious when applied to the lungs, or to an abraded surface ; thus carbonic acid is continually swallowed with fermented liquors with impunity, and the poison of the viper may be taken in the same manner : whilst inspiring carbonic acid kills, and the poison of the viper inserted into the flesh often proves fatal.

There is again a third kind of substances which act as poisons whether applied externally or internally, as arsenic.

When a substance produces disease not only in mankind but in all animals, it is distinguished by the term common poison, as arsenic, sublimate, &c. whilst that which is poisonous to man only, or to animals, and often to one genus, is said to be a relative poison ; thus aloes are poisonous to dogs and wolves ; the phellandrium aquaticum kills horses, whilst oxen devour it greedily, and with impunity. It appears, then, that substances act as poisons only in regard to their dose, the part of the body they are applied to, and the subject.

Poisons may enter the body in the following ways :

1. Through the œsophagus with the food.
2. Through the anus with gylsters.
3. Through the nostrils with odorous substances.
4. Through the lungs with the air.
5. Through the absorbents of the skin, either whole, ulcerated, cut, or torn.

In regard to the nature of their constituent principles, they are divided into

1. Acrid poisons, as drastic and corrosive vegetables ; acid, alkaline, metallic, and acido-metallic minerals ; deleterious and necrotic animals.
2. Narcotic, as certain vegetables.
3. Narcotico-acrid, which kill with both principles.
4. Halituous, which suffocate by a noxious vapour.
5. Mechanical poisons, which act by their mechanical power.

In regard of the symptoms which are produced by poisons, they are divided into

POISON.

1. Inflammatory, which induce inflammation and gangrene.
 2. Drastic, which operate by purging and vomiting.
 3. Convulsive, which excite spasms and convulsions.
 4. Paralytic, which induce palsy of the extremities and heart: as lead preparations, the lauro-cerasus, &c.
 5. Narcotic, which cause coma, amaurosis, and delirium.
 6. Suffocative, which suffocate by a mephitic vapour.
 7. Exsiccant, which bring on tabes; as lead preparations.
 8. Sceptic, which induce a tendency to putridity in the blood and gangrene.
- We shall now offer a table of poisons under the four classes we have adverted to.

I. ANIMAL POISONS.

American snakes.

1. *Crotalus horridus*.
Its antidote is the radix seneka; volatile alkali, and common salt.
2. *Crotalus miliaris*.
3. *Crotalus dryinus*.
4. *Crotalus durissus*.
5. *Crotalus mutus*.
6. *Crotalus atropos*.
7. *Coluber heberis*.
8. *Coluber dipsas*.
9. *Coluber myctericans*.
10. *Coluber lacteus*.

The antidote to all these are the seneka root, volatile alkali, and common salt.

Asiatic serpents.

11. *Coluber naga*.
12. *Coluber severus*.
13. *Coluber stolatus*.
14. *Coluber atrox*.
15. *Coluber corallinus*.
16. *Coluber ammodytes*.
17. *Coluber lebetinus*.

The antidote to all these is the radix mungos internally, with the general caustic applications, extirpation, &c.

African serpents.

18. *Coluber vipera*.
19. *Coluber niveus*.
20. *Coluber haje*.

Caustic application, extirpation, &c. are generally adopted.

European serpents.

21. *Coluber berus*.

The leaves of the fraxinus, eau de luce, &c. are applied to the bite of this serpent.

22. *Coluber prester*.

Its antidote is olive oil.

23. *Coluber cherssea*.

Scarification, cupping glasses, and Spanish flies powdered are applied to the bite.

24. *Coluber aspis*.

Volatile alkali is here most efficacious, both internally and externally.

25. *Coluber illyricus*.

The radix gentiana, with mercury, are given internally.

Poisonous insects.

1. *Furia infernalis*.

Extirpation.

2. *Lytta vesicatoria*.

When Spanish flies are swallowed in too large a dose, emetics, purgatives, and mucilaginous and oily drinks are given.

3. *Meloe majalis*.

4. *Meloe proscarabæus*.

The same antidote as the Spanish fly.

5. *Scorpio Africanus*.

Its antidote is the application of oil.

6. *Phalangium arachnoides*.

Treacle is applied with success.

7. *Culex lanius*.

8. *Sirexigas*.

The antidote to these are oily applications.

9. *Buprestis*.

These insects, when swallowed, kill, unless oil and vomits are given.

10. *Aranea domestica*.

11. *Aranea tarantula*.

Applications of volatile alkali are most efficacious.

12. *Pulex Americanus*.

This very small insect penetrates the cuticle, and requires extirpation.

13. *Culex pipeas*.

14. *Culex pulicaris*.

Volatile alkali allays the swelling produced by these insects.

15. *Apis mellifica*.

16. *Vespa vulgaris*.

17. *Vespa crabro*.

Cold water with vinegar or sugar of lead, allay the mischief they create.

Poisonous worms.

1. *Gordius medenensis*.

This singular worm must be gradually twisted round any substance, and thus drawn out from underneath the skin.

2. *Gordius marinus*.

The internal use of antiscorbutics: this worm producing a species of leprosy.

3. *Hirudo venetatus*.

When this leach is swallowed, salt and water, and oil, must be taken to kill it.

4. *Tethys marina*.

5. *Urtica marina*.

Cold water and volatile alkali should be applied.

Amphibious poisonous animals.

1. *Rana bufo*.

2. *Lacerta geko*.

3. *Lacerta salamandra*.

Volatile alkaline applications, with cold water, are applied with advantage.

Poisonous fishes.

1. *Tetradon scellatus*.

2. *Tetradon lineatus*.

3. *Trachinus draco*.

4. *Perca venenosa*.

Vomits and acids of lemon are to be exhibited against these.

5. *Raia pastinaca*.

This produces a wound very difficult of cure.

6. *Raia torpedio*.

The touch of this fish produces a paralytic affection of the arm for some little time.

7. *Gymnotus electricus*.

This strikes the part which touches it like a shock of electricity.

POISON.

3. Sparus pagurus.

Emetics and acids are to be given when this is swallowed.

Other animal poisons.

1. Mytilus edulis.
2. Ostrea venenata.
3. Ovum putridum.
4. Pinguedo rancida.
5. Animal putridum.

Vomits are first to be given, then aromatics.

6. Miasma luis bovillæ.

The pustules and ulcers from the cow pox are cured by purgatives and detersive applications.

7. Virus rabiorum.

When hydrophobia is induced, no remedy has hitherto been found efficacious. Extirpation, immediately after the wound is inflicted, is the only certain prophylaxis.

8. Virus variolosum.
9. Virus morbillosum.
10. Virus scarlatinum.
11. Virus scabiosum.
12. Virus venereum.
13. Virus plicosum.
14. Virus cancrorum.
15. Virus leprosum.
16. Virus pestilential.

All these are considered under the medicinal treatment of small pox, measles, scarlatina, &c.

II. VEGETABLE POISONS.

Narcotic poisonous vegetables.

1. Papaver somniferum.

Vomits, acids, and the other anti-narcotics mentioned at the end of this table, are the antidotes.

2. Opium.

This requires the same antidotes.

3. Physalis somnifera.
4. Solanum lycopersicum.
5. Solanum mammosum.
6. Solanum insanum.
7. Solanum dulcamara.
8. Solanum nigrum.
9. Atropa mandragora.
10. Datura stramonium.
11. Datura metel.
12. Datura ferox.
13. Datura tatula.
14. Hyosciamus niger.

The antidotes are first vomits, which also purge, then vinegar and oil.

15. Hyosciamus albus.
16. Hyosciamus physalodes.
17. Hyosciamus scopolia.
18. Azalea pontica.
19. Antirrhinum orontium.
20. Actæa spicata.
21. Lolium temulentum.
22. Ervum ervilia.
23. Lathyrus cicera.
24. Peganum harmela.
25. Chenopodium hybridum.
26. Cheledonium glaucium.
27. Taxus baccata.
28. Lactuca virosa.
29. Lactuca scariolo.
30. Paris quadrifolia.
31. Prunus lauro-cerasus.

Against all these narcotics are recommended, after vomiting.

1. Acids; as vinegar, lemon juice, spirits of vitriol diluted.

2. A very strong infusion of Turkey coffee.

3. Small doses of ipecacuan, to promote a powerful sweating.

4. Glysters of vinegar, or soap dissolved.

5. Blisters to the neck.

6. Wine.

7. Alkaline salts and borax.

Narcotic and acrid vegetable poisons.

1. Hippomane manciella.

An emetic and purge, then milk and rice broth.

2. Hippomane biglandulosa.
3. Cocculus indicus.
4. Coriaria myrtifolia.
5. Strychnos nux vomica.
6. Strychnos colubrina.
7. Ignatia amara.
8. Nerium oleander.
9. Atropa belladonna.
10. Nicotiana tabacum.
11. Nicotiana rustica.
12. Nicotiana paniculata.
13. Nicotiana glutinosa.
14. Bryonia alba.
15. Chærophyllum sylvestre.
16. Chærophyllum bulbosum.
17. Chærophyllum temulentum.
18. Cethusa cynapium.
19. Sium latifolium.
20. Cicuta virosa.
21. Conium maculatum.
22. Mercurialis perennis.

Poisonous fungi.

1. Agaricus muscarius.
2. Agaricus integer venenatus, Krapff.
3. Agaricus integer viscidus, Krapff.
4. Agaricus lactifluus venenatus, Krapff.
5. Agaricus piperatus.
6. Agaricus fimetarius.
7. Agaricus pustulatus.
8. Agaricus necator.
9. Agaricus sanguineus.
10. Agaricus viscidus.
11. Agaricus clypeatus.
12. Boletus versicolor.
13. Boletus elegans.
14. Boleti parasitica.
15. Phallus impudicus.
16. Phallus mukusin.
17. Lycoperdon carcinomalis.
18. And several others not yet scientifically named.

Acrid vegetable poisons.

1. Delphinia staphisagria.
2. Veratrum sabadilla.
3. Rhododendron corysanthium.
4. Fritillaria imperialis.
5. Colchicum autumnale.
6. Pedicularis palustris.
7. Digitalis purpurea.
8. Cyclamen europæum.
9. Plumbago europæa.
10. Convolvulus scammonium.
11. Cucumis colocynthis.
12. Momordica elaterium.
13. Gambogia gutta.
14. Cerbera abhovei.
15. Cerbera manghas.

POISON.

16. *Cynanchum erectum*.
17. *Lobelia syphilitica*.
18. *Lobelia longifolia*.
19. *Cynanchum vimiale*.
20. *Apocynum androseifolium*.
21. *Apocynum cannabinum*.
22. *Apocynum venetum*.
23. *Asclepias gigantea*.
24. *Hydrocotyle vulgaris*.
25. *Oenanthe fistulosa*.
26. *Oenanthe crocata*.
27. *Scandix infesta*.
28. *Thapsia fetida*.
29. *Alisma plantago aquatica*.
30. *Clematis vitalba*.

120. *Secale cornutum*. Its antidote is milk.

The usual and most approved antidotes to all these are, after vomiting and purging, emollient substances; as panada, with butter, and wine and cordials to support the strength.

Glutinous vegetable poisons.

1. *Ilex aquifolium*.
2. *Viscum album*.
3. *Rosa canina*.

III. MINERAL POISONS.

Mechanical mineral poisons.

1. *Vitrum contusum*.
2. *Smalta*.
3. *Gemma adamas*.
4. *Amianthus plumosus*.
5. *Cuprum lapis lazuli*.
6. *Fuligo caminorum*.

Mucilaginous substances, with oil or butter, are found to be most serviceable against these.

Poisonous earths commonly so termed.

1. Gypsum.
2. Selenites.
3. Nitrum crystallus montana.

Mucilaginous and oily substances, with absorbent earth, are given to obviate the symptoms arising from these.

Poisonous acids.

1. Acidum sulphuricum.
2. Acidum muriaticum.
3. Acidum nitricum.
4. Acidum nitrosum.
5. Aqua regia.
6. Zincum vitriolatum.
7. Cuprum vitriolatum.
8. Ferrum vitriolatum.

Alkalis and oily medicines only are serviceable, and antiphlogistics.

POISON.

Alkaline poisons.

1. Natron purum.
2. Soda pura.
3. Aquæ ammoniæ pura.
4. Lapis causticus.
5. Aqua natri puri.
6. Calx pura.

Diluted acids are to be given immediately, then oily and mucilaginous substances.

Common metallic poisons.

1. Aurum fulminale.
2. Preparata argenti.
3. Preparata bismuthi.
4. Preparata cupri.
5. Preparata plumbi.
6. Preparata stanni.

Alkaline salts, vomiting after; with milk and oily foods.

Mercurial poisons.

1. Hydrargyrum muriatum.
2. Calomel as impurus.
3. Hydrargyrum muriatum mitis.
4. Calx hydrargyri alba.
5. Hydrargyrum nitratum ruber.
6. Hydrargyrum vitriolatum.

Alkaline salts are recommended as the best antidotes against mercurial poisons.

Antimonial poisons.

1. Antimonium.
2. Antimonium sublimatum.
3. Antimonium muriatum.
4. Vitrum antimonii.
5. Crocos antimonii.
6. Antimonium tartarisatum.
7. Mercurius vitæ.
8. Hepar antimonii.
9. Sulphur antimonii præcipitatum.

Oily and mucilaginous substances, with cordials, and then opium, allay the violent vomiting and purging usually produced by antimonial preparations.

Arsenical poisons.

1. Arsenicum album.
2. Arsenicum flavum.
3. Arsenicum rubrum.
4. Auripigmentum.
5. Arsenicum.
6. Arsenicum porosum.
7. Cobaltum arsenicale.

The hepar sulphuris is found the best antidote against arsenical preparations.

IV. GASSEOUS OR HALITUOUS POISONS.

Poisonous mineral acid vapours.

1. Halitus sulphuris accensi.
2. Gaz acidi sulphurici.
3. Gaz acidi muriatici.
4. Gaz acidi nitrosi.
5. Gaz acidum carbonicum.
 - a. In the Grotto del Cano, &c.
 - b. From fermenting liquors.
 - c. From fermenting dough.
 - d. From the waters of Pyrmont, &c.
 - e. From the burning of lime.
 - f. From the burning of bricks, &c.

Pure air thrown into the lungs through a tube introduced into the trachea; stimulating volatile applications thrown into the stomach, and tobacco glysters, are recommended.

Poisonous alkaline vapours.

1. Alkali volatile, from putrid urine, &c.

Putrid vapours.

1. From dead putrifying animals.
2. From dead putrifying vegetables.
3. Air corrupted by breathing.
4. Air corrupted by animal perspiration.

The best antidote is pure air.

The most difficult poisons to be detected by those who are not acquainted with the nature of chemical re-agents are the metallic, and they are among those that most frequently produce mischief upon an extensive scale; especially the oxyds of copper and of lead, which are so often found injurious in culinary preparations from their metals being so largely employed in the manufacture of culinary vessels. All these are best detected by those substances which have of late years been called colourific acids, as sulphuretted hydrogen, Prussic acid, gallic acid, and tannin. All these act, even in small quantities, with great energy upon metallic solutions, however minute the quantity of metal dissolved, entering into a combination with the oxyds, and precipitating them in powders remarkable for the intensity and variety of their colours. The first, however, is the most active and the most comprehensive in its operation; and is hence that which is most usually resorted to on such occasions.

We have said that poisonous substances produce very different effects according to the manner they are introduced into the system: a very curious subject of enquiry, and which has within the last year or two been pursued so successfully, and with such singular results by Mr. Brodie, that we shall make no apology to our readers for copying the following extract from his paper upon this subject, introduced into the Philosophical Transactions for 1811.

"The substances, observes Mr. Brodie, which act as poisons when applied to the animal body are very numerous. In the experiments which I have hitherto made, I have employed vegetable poisons only. Of these I have selected such as are very active and certain in producing their effects, believing that, on this account, the exact nature of those effects would be more readily ascertained. The principal objects which I have kept in view have been to determine, on which of the vital organs the poison employed exercises its primary influence, and through what medium that organ becomes affected. I have also endeavoured to ascertain by what means the fatal consequences of some poisons may be prevented. With some of the conclusions which I have ventured to draw, so far as I know, we were not before acquainted; and others of them, though not entirely new, had not been previously established by satisfactory experiments.

I shall relate first those experiments in which poisons were employed internally, that is, to the mucous membranes of the tongue or alimentary canal, and afterwards those in which poisons were applied to wounded surfaces.

I. EXPERIMENTS WITH POISONS APPLIED TO THE TONGUE OR ALIMENTARY CANAL.

Alcohol.

When spirits are taken into the stomach in a certain quantity, they produce that kind of delirium which constitutes intoxication: when taken in a larger quantity, it is well known that they destroy life altogether, and that in the

POISON.

course of a very short space of time. Intoxication is a derangement of the functions of the mind, and, as these are in some way connected with those of the brain, it seems probable, that it is by acting on this organ that spirits when taken into the stomach occasion death. In order to ascertain how far this conclusion is just, I made the following experiments.

Exp. 1.—I poured two drachms of proof spirits down the œsophagus of a cat. Instantly he struggled violently; then lay on one side, perfectly motionless and insensible; the breathing was laboured and stertorous, and the pulsations of the heart were very frequent. He continued in this state for seven or eight minutes; then began to recover; the respirations became easier, and presently he stood up, and was able to walk.

Exp. 2.—I injected an ounce and a half of proof spirits into the stomach of a large full-grown rabbit, by means of an elastic gum tube passed down the œsophagus. The same symptoms took place as in the last experiment; but the animal did not begin to recover from the state of insensibility until forty minutes had elapsed from the time of the injection.

Exp. 3.—Seven drachms of proof spirits were injected into the stomach of a young rabbit. Two minutes afterwards, he was evidently affected by the spirits, and in three minutes more he lay on one side motionless and insensible. The pupils of the eyes were perfectly dilated; there were occasional slight convulsive motions of the extremities; the respiration was laborious, it was gradually performed at longer and longer intervals, and at the end of an hour and fifteen minutes had entirely ceased. Two minutes after the animal was apparently dead, I opened into the thorax, and found the heart acting with moderate force and frequency, circulating dark-coloured blood. I introduced a tube into the trachea, and produced artificial respiration by inflating the lungs, and found that by these means the action of the heart might be kept up to the natural standard, as in an animal from whom the head is removed.

Exp. 4.—I injected into the stomach of a rabbit two ounces of proof spirits. The injection was scarcely completed, when the animal became perfectly insensible. Precisely the same symptoms took place as in the last experiment, and at the end of twenty-seven minutes, from the time of the injection, the rabbit was apparently dead; but on examining the thorax the heart was found still acting, as in the last experiment.

It has been shown by M. Bichat, and the observation has been confirmed by some experiments which I have lately had the honour of communicating to this learned society, that the brain is not directly necessary to the action of the heart, and that when the functions of the brain are destroyed, the heart continues to contract for some time afterwards, and then ceases only in consequence of the suspension of respiration, which is under the influence of the brain.

It would appear, from the experiments which I have just detailed, that the symptoms produced by a large quantity of spirits taken into the stomach arise entirely from disturbance of the functions of the brain. The complete insensibility to external impressions; the dilatation of the pupils of the eyes; and the loss of motion, indicate that the functions of this organ are suspended; respiration, which is under its influence, is ill performed, and at last altogether ceases; while the heart, to the action of which the brain is not directly ne-

cessary, continues to contract, circulating dark-coloured blood for some time afterwards.

There is a striking analogy between the symptoms arising from spirits taken internally, and those produced by injuries of the brain.

Concussion of the brain, which may be considered as the slightest degree of injury, occasions a state of mind resembling intoxication; and the resemblance in some instances is so complete, that the most accurate observer cannot form a diagnosis, except from the history of the case. Pressure on the brain, which is a more severe injury than concussion, produces loss of motion, insensibility, dilatation of the pupils; respiration becomes laboured and stertorous, is performed at long intervals, and at last altogether ceases, and the patient dies.

It forms an interesting matter of enquiry, whether spirits when taken into the stomach produce their effects on the brain by being absorbed into the circulation, or in consequence of the sympathy that exists between these organs by means of the nerves. The following circumstances lead me to conclude that they act in the last of these two ways.

1. In experiments where animals have been killed by the injection of spirits into the stomach, I have found this organ to bear the marks of great inflammation, but never found any preternatural appearances whatever in the brain. 2. The effects of spirits taken into the stomach in the last experiment were so instantaneous, that it appears impossible that absorption should have taken place before they were produced. 3. A person who is intoxicated, frequently becomes suddenly sober after vomiting. 4. In the experiments which I have just related, I mixed tincture of rhubarb with the spirits, knowing from the experiments of Mr. Home, and Mr. William Brande, that this, when absorbed into the circulation, was readily separated from the blood by the kidneys, and that very small quantities might be detected in the urine by the addition of potash; but, though I never failed to find urine in the bladder, I never detected rhubarb in it.

The including the termination of the thoracic duct in a ligature does not prevent spirits, when taken into the stomach, from producing their usual effects on the nervous system; but subsequent observations, which Mr. Home has already communicated to this society, have shown that no conclusion can be drawn from this experiment.

That a poison may affect a distant organ, through the medium of the nerves, without entering the circulation, is proved by the well-known circumstance of solution of the extract of belladonna, when applied to the tunica conjunctiva of the eye, occasioning dilatation of the pupil of the same eye, though no other part of the system is affected.

It has been formerly supposed by Dr. Mead and other physiologists, that a poison may produce death by acting on the extremities of the nerves of the stomach and intestines, without being absorbed into the circulation. That it should by these means be capable of affecting the brain is not to be wondered at, when we consider the numerous and various sympathies between this organ and the alimentary canal, evidently independent of any other communication than the nerves.

Essential oil of bitter almonds.

Exp. 5.—One drop of the essential oil of bitter
K K 2

POISON.

almonds was applied to the tongue of a young cat. She was instantly ceased with violent convulsions, then lay on one side motionless, insensible; breathing in a hurried manner; the respirations became laboured, took place at longer and longer intervals, and at the end of five minutes, from the application of the poison, had entirely ceased, and the animal was apparently dead; but on opening the thorax, the heart was found acting regularly eighty times in a minute; circulating dark-coloured blood, and it continued to act for six or seven minutes afterwards.

Exp. 6.—I injected into the rectum of a cat half an ounce of water, with two drops of the essential oil. In two minutes afterwards, he was affected with symptoms similar to those which occurred in the last experiment, and at the end of five minutes, from the injection of the poison, he was apparently dead. Two minutes after apparent death, the heart was found acting eighty times in a minute. On dissection, no preternatural appearances were found either in the internal membrane of the rectum, or the brain.

The symptoms produced by this poison, and the circumstance of the heart continuing to contract after apparent death, lead to the conclusion that it occasions death by disturbing the functions of the brain.

While engaged in these last experiments, I dipped the blunt end of a probe into the essential oil, and applied it to my tongue, meaning to taste it, and having no suspicion that so small a quantity could produce any of its specific effects on the nervous system; but scarcely had I applied it, when I experienced a very remarkable and unpleasant sensation, which I referred chiefly to the epigastric region, but the exact nature of which I cannot describe, because I know nothing precisely similar to it. At the same time there was a sense of weakness in my limbs, as if I had not the command of my muscles, and I thought that I was about to fall. However, these sensations were momentary, and I experienced no inconvenience whatever afterwards.

I afterwards applied a more minute quantity of the essential oil to my tongue several times, without experiencing from it any disagreeable effects; but on applying a larger quantity, I was affected with the same momentary sensations as in the former instance, and there was a recurrence of them in three or four seconds after the first attack had subsided.

From the instantaneousness with which the effects are produced; and from its acting more speedily, when applied to the tongue than when injected into the intestine, though the latter presents a better absorbing surface, we may conclude that this poison acts on the brain through the medium of the nerves, without being absorbed into the circulation.

Juice of the leaves of aconite.

Exp. 7.—An ounce of this juice was injected into the rectum of a cat. Three minutes afterwards he voided what appeared to be nearly the whole of the injection; he then stood for some minutes perfectly motionless, with his legs drawn together; at the end of nine minutes, from the time of the injection, he retched and vomited; he then attempted to walk, but faltered and fell at every step, as if from giddiness. At the end of thirteen minutes, he lay on one side insensible, motionless, except some slight convulsive motions

of the limbs. The respiration became slow and laboured; and at forty-seven minutes from the time of the injection, he was apparently dead. One minute and a half afterwards, the heart was found contracting regularly one hundred times in a minute.

It appears from this experiment, that the juice of aconite, when injected into the intestine, occasions death by destroying the functions of the brain. From the analogy of other poisons, it is rendered probable that it acts on the brain through the medium of the nerves, without being absorbed into the circulation. This opinion is confirmed by the following circumstance: if a small quantity of the leaf of aconite is chewed, it occasions a remarkable sense of numbness of the lips and gums, which does not subside for two or three hours.

Infusion of tobacco.

Exp. 8.—Four ounces of infusion of tobacco were injected into the rectum of a dog. Four minutes afterwards he retched, but did not vomit; he then became faint, and lay motionless on one side; at the end of nine minutes from the time of the injection, the heart could not be felt; he gasped for breath at long intervals; and in another minute there was no appearance whatever of life. I immediately laid open the cavities of the thorax and abdomen. The heart was much distended, and had entirely ceased to contract; there was no peristaltic motion of the intestines.

Exp. 9.—An ounce of very strong infusion of tobacco was injected into the rectum of a cat. Symptoms were produced similar to those which occurred in the last experiment, and the animal died at the end of seven minutes from the time of the injection. On opening the thorax immediately after death, the heart was found extremely distended, and to have entirely ceased acting, with the exception of a slight tremulous motion of the auricles.

Exp. 10.—Three ounces of infusion of tobacco were injected into the rectum of a dog. He was affected with symptoms similar to those in the former experiments, and died at the end of ten minutes. On opening the thorax immediately after death, I found the heart much distended, and to have entirely ceased contracting.

Exp. 11.—Three ounces of infusion of tobacco were injected into the rectum of a dog. Immediately there took place tremulous contractions of the voluntary muscles. Five minutes afterwards the injection was repeated in the same quantity. The dog then was sick, and threw up some of the infusion, with other matter, from the stomach; he became faint, and died ten minutes after the second injection. Immediately after respiration had ceased, I opened the thorax, and found the heart extremely extended, and without any evident contraction, except of the appendix of the right auricle, which every now and then contracted in a slight degree. I divided the pericardium on the right side. In consequence of the extreme distension of the heart, this could not be done without irritating the fibres with the point of the scalpel. Immediately both auricles and ventricles began to contract with considerable force, so as to restore the circulation. Artificial respiration was produced, and the circulation was kept up for more than half an hour, beyond which time the experiment was not continued.

We may conclude from these experiments, that the effect of the infusion of tobacco, when injected

POISON.

into the intestine of a living animal, is to destroy the action of the heart, stopping the circulation and producing syncope. It appeared to me that the action of the heart ceased even before the animal had ceased to respire; and this was confirmed by another experiment, in which, in a dog killed by the infusion of tobacco, I found the cavities of the left side of the heart to contain scarlet blood, while in those of the right side the blood was dark-coloured. This poison therefore differs materially from alcohol, the essential oil of almonds, and the juice of aconite, which have no direct influence on the action of the heart. The infusion of tobacco renders the heart insensible to the stimulus of the blood, but it does not altogether destroy the power of muscular contraction, since the heart resumed its action in one instance on the division of the pericardium, and I have found that the voluntary muscles of an animal killed by this poison are as readily stimulated to contract by the influence of the Voltaic battery, as if it had been killed in any other manner. At the same time, however, that the infusion of tobacco destroys the action of the heart, it appears to destroy also the functions of the brain, since these did not return in the last experiment; although the circulation was restored, and kept up by artificial respiration.

Since there is no direct communication between the intestinal canal and the heart, I was at first induced to suppose that the latter becomes affected in consequence of the infusion being conveyed into the blood by absorption. Some circumstances in the following experiment have since led me to doubt whether this is the case.

Exp. 12.—In a dog, whose head was removed, I kept up the circulation by means of artificial respiration, in the manner already described in the account of some experiments which I lately communicated to this society. I then injected into the stomach and intestines nine ounces of infusion of tobacco. At the time of the injection, the body of the animal lay perfectly quiet and motionless on the table; the heart acted regularly one hundred times in a minute. Ten minutes afterwards the pulse rose to one hundred and forty in a minute; the peristaltic motion of the intestines was much increased, and the voluntary muscles in every part of the body were thrown into repeated and violent spasmodic action. The joints of the extremities were alternately bent and extended; the muscles of the spine, abdomen, and tail alternately relaxed and contracted, so as to turn the whole animal from one side to the other. I have observed, in other instances, spasmodic actions of the muscles, where the circulation was kept up by artificial respiration, after the removal of the head, but not at all to be compared, either in strength or frequency, with those which took place on this occasion. I made pressure on the abdominal aorta for more than a minute, so as to obstruct the circulation of the blood in the lower extremities; but the muscular contractions were not lessened in consequence. Half an hour after the injection of the infusion, the artificial respiration was discontinued. The heart continued to act, circulating dark-coloured blood; the muscular contractions continued, but gradually diminished, in strength and frequency. I tied a ligature round the vessels at the base of the heart, so as to stop the circulation; nevertheless the muscular contractions still continued, though less frequent and forcible than before, and some minutes elapsed before they entirely ceased.

In this experiment, the disposition to contraction in the muscles was very much increased, instead of being diminished, as in those just related. If the infusion of tobacco influences the heart from being absorbed into the blood, and thus coming into actual contact with its fibres, there is no evident reason why the removal of the brain, and the employment of artificial respiration, should occasion so material a difference in its effects. If the contractions of the voluntary muscles had depended on the infusion circulating with the blood, it is reasonable to suppose that the pressure on the aorta would have occasioned some diminution of them, and that the complete obstruction of the circulation would have caused them to cease altogether.

From these considerations, I am induced, on the whole, to believe that the infusion of tobacco, when injected into the intestines, influences the heart through the medium of the nervous system; but I have not been able to devise any experiment, by which the truth or fallacy of this opinion might be put beyond the reach of doubt.

It appears remarkable, that the brain and nervous system, although not necessary to the action of the heart, should, when under the influence of the infusion of tobacco, be capable of influencing this organ so as to stop its action; but this is analogous to what we see occur in consequence of violent emotions of the mind. Those states of the nervous system which accompany the passions of joy, fear, or anger, when existing in a moderate degree, render the heart more sensible to the stimulus of the blood, and increase the frequency of its contractions; while, when the same passions exist in a greater degree, the heart is rendered altogether insensible to the stimulus of the blood, and syncope ensues.

Empyreumatic oil of tobacco.

Exp. 13.—Less than a drop of this oil was applied to the tongue of a young cat. Instantly violent convulsions took place in all the muscles, and the respirations became very frequent. In five minutes after the application, she lay on one side insensible, with slight spasmodic actions of the muscles. At the end of eleven minutes she retched, but did not vomit. In a quarter of an hour she appeared to be recovering. I repeated the application of the poison, and she was again seized with violent convulsions, and became insensible, breathing at long intervals; and in two minutes from the second application respiration had entirely ceased, and she was apparently dead. On opening the thorax, I found the heart acting with regularity and strength, circulating dark-coloured blood. I introduced a tube into the trachea, and produced artificial respiration; the contractions of the heart became augmented in force and frequency, and there was no evident diminution in six or seven minutes, during which the artificial respiration was continued.

On dissection, nothing remarkable was found in the appearance of the tongue or brain.

The symptoms and mode of death, in this experiment, did not essentially differ from those produced by the essential oil of almonds. I was surprised to find the effects of the empyreumatic oil so entirely different from those of the infusion of tobacco. Supposing that this difference might arise from the poison being more concentrated in the oil than in the infusion, I made the following experiments.

Exp. 14.—A drop of the oil of tobacco was sus-

POISON.

pended in an ounce and a half of water by means of muelleage of gum arabic, and the whole was injected into the rectum of a dog. In two minutes afterwards he became faint, retched, but did not vomit. He appeared to be recovering from this state, and in twenty-five minutes after the first injection it was repeated in the same quantity. He was then seized with symptoms similar to those in the last experiment, and in two minutes and a half he was apparently dead.

Two minutes after apparent death, on the thorax being opened into, the heart was found acting regularly one hundred times in a minute, and it continued acting for several minutes.

Exp. 15.—A drop of the empyreumatic oil of tobacco with an ounce of water was injected into the rectum of a cat. The symptoms produced were in essential circumstances similar to those which occurred in the last experiment. The animal was apparently dead five minutes after the injection, and the heart continued to contract for several minutes afterwards.

We may conclude from these experiments, that the empyreumatic oil of tobacco, whether applied to the tongue or injected into the intestine, does not stop the action of the heart and induce syncope, like the infusion of tobacco; but that it occasions death by destroying the functions of the brain, without directly acting on the circulation. In other words, its effects are similar to those of alcohol, the juice of aconite, and the essential oil of almonds.

XL. EXPERIMENTS WITH POISONS APPLIED TO WOUNDED SURFACES.

Essential oil of almonds.

Exp. 16.—I made an incision in the thigh of a rabbit, and introduced two drops of essential oil between the skin and the muscles. In four minutes after the application, he was seized with violent convulsions, and became insensible, and in two minutes more he was apparently dead; but the heart was felt through the ribs acting one hundred and twenty times in a minute, and it continued acting for several minutes. There were no other appearances in the limb than would have resulted from an ordinary wound.

Exp. 17.—Two drops of the essential oil of almonds were introduced into a wound in the side of a mouse. Two minutes afterwards he was affected with symptoms similar to those which occurred in the last experiment, and in two minutes more he was apparently dead, but the heart continued to contract for some minutes afterwards.

From the experiments which I have just related, and from others which it appears unnecessary to detail, as the general results were the same, I have learned that where the essential oil of almonds is applied to a wound, its effects are not so instantaneous as when it is applied to the tongue; otherwise there is no difference in its effects, in whatever manner it is applied.

Juice of the leaves of aconite.

Exp. 18.—I made a wound in the side of a young rabbit, and introduced, between the skin and muscles, about twenty drops of the juice of aconite. Twenty-three minutes afterwards he was affected with symptoms in all essential respects similar to those which occurred in an experiment already related, where the juice was injected into the rectum, and at the end of forty-seven minutes from the application of the poison

he was apparently dead. Two minutes after apparent death, the heart was found contracting, but very feebly.

Woorara.

The woorara is a poison with which the Indians of Guiana arm the points of their arrows. It appears not to differ essentially from the ticunas, which was employed in the experiments of the Abbé Fontana.

Exp. 19.—A small quantity of the woorara in powder was applied to a wound in the side of a Guinea pig. Ten minutes afterwards the animal was unable to walk; then he became quite motionless, except some slight occasional convulsions. He gradually became insensible; the respirations were laboured, and at the end of fourteen minutes from the application of the poison the respiration had entirely ceased, and he was apparently dead; but on opening the thorax, the heart was found acting seventy times in a minute, circulating dark-coloured blood, and it continued to contract for several minutes afterwards. On dissection no preternatural appearances were observed in the brain, nor was there any other appearance in the limb than would have arisen from an ordinary wound.

Exp. 20.—I made a wound in the side of a Guinea pig, and introduced into it about two grains of the woorara in powder. At the end of twenty-five minutes, symptoms took place very similar to those which occurred in the last experiment, and in thirteen minutes more the animal was apparently dead; but the heart continued to contract one hundred and eight times in a minute, and by means of artificial respiration the circulation was kept up for more than twenty minutes.

The results of other experiments which I have made with the woorara were similar to those just described. The heart continued to act after apparent death, and the circulation might be kept up by means of artificial respiration. It is evident that this poison acts in some way or other on the brain, and that the cessation of the functions of this organ is the immediate cause of death.

I found in these experiments, that the best mode of applying the woorara is when it is dissolved in water to the consistence of a thin paste. I first made the wound, and then smeared the poison over it with the end of the scalpel. I found that the animal was more speedily and certainly affected if there was some hæmorrhage, unless the hæmorrhage was very copious, when it produced an opposite effect, by washing the poison away from the wound. When the poison was applied in large quantity, it sometimes began to act in six or seven minutes. Never more than half an hour elapsed from the time of the poison being inserted to that of the animal being affected, except in one instance, where a ligature was applied on the limb, which will be mentioned afterwards. The woorara, which I employed, had been preserved for some years, which will account for its having been less active than it has been described to be by those who had witnessed its effects when in a recent state.

Upas antiar.

The island of Java produces two powerful vegetable poisons, to one of which the natives give the name of upas tieutè, and to the other that of upas antiar.

Exp. 21.—About two grains of this poison were

POISON.

made into a thin paste with water, and inserted into a wound in the thigh of a dog. Twelve minutes afterwards he became languid; at the end of fifteen minutes, the heart was found to beat very irregularly, and with frequent intermissions; after this, he had a slight rigor. At the end of twenty minutes, the heart beat very feebly and irregularly; he was languid; was sick and vomited; but the respirations were as frequent and as full as under natural circumstances, and he was perfectly sensible. At the end of twenty minutes he suddenly fell on one side, and was apparently dead. I immediately opened into the thorax, and found the heart distended with blood in a very remarkable degree, and to have entirely ceased contracting. There was one distinct and full inspiration after I had begun making the incision into the thorax. The cavities of the left side of the heart contained scarlet blood, and those of the right side contained dark-coloured blood, as in a living animal.

Exp. 22.—A small quantity of the upas antiar, prepared as before, was inserted into a wound in the thigh of a young cat. She appeared languid in two minutes after the poison was inserted. The symptoms which took place did not essentially differ from those which occurred in the last experiment, except that there were some convulsive motions of the limbs. At eight minutes after the poison was inserted, she lay on one side motionless and insensible, the heart could not be felt, but the respiration had not entirely ceased. On opening into the thorax, I found the heart to have ceased contracting. It was much distended with blood; and the blood in the cavities of the left side was of a scarlet colour. There were two full inspirations after the incision of the thorax was begun. On irritating the heart with the point of the scalpel, slight contractions took place in the fibres of the appendices of the auricles, but none in any other part.

Exp. 23.—The experiment was repeated on a rabbit. The symptoms produced were similar to those in the last experiment; but the animal did not vomit, and the convulsive motions were in a less degree: he died eleven minutes after the poison was inserted. On opening the chest, the heart was found to have entirely ceased contracting; it was much distended with blood; and the blood in the cavities on the left side was of a scarlet colour. On irritating the heart with the point of the scalpel, the ventricles contracted, but not sufficiently to restore the circulation.

Exp. 24.—About a grain of the upas antiar was inserted into a wound in the side of a rabbit. He was affected with symptoms similar to those before described, and died in ten minutes after the poison was applied. On opening the thorax immediately after death, the heart was found to have ceased contracting, and the blood in the cavities of the left side was of a scarlet colour.

It appears from these experiments, that the upas antiar, when inserted into a wound, produces death (as infusion of tobacco does when injected into the intestines) by rendering the heart insensible to the stimulus of the blood, and stopping the circulation. The heart beats feebly and irregularly before either the functions of the mind or the respiration appear to be affected. Respiration is performed even after the circulation has ceased; and the left side of the heart is found after death to contain scarlet blood, which never can be the case where the cause of death is the cessation of the functions of the brain or lungs. The convulsions which occur when the circulation has

nearly ceased, probably arise from the diminution of the supply of blood to the brain, resembling those which take place in a person who is dying from hæmorrhage.

There remains an interesting subject of enquiry, "through what medium do poisons influence the brain when applied to wounds?" That poisons applied in this manner do not produce their effects precisely in the same way as poisons taken internally, is rendered probable by this circumstance; that some poisons, which are very powerful when applied to wounds even in small quantities, are either altogether inefficient when taken internally, or require to be given in very large quantities, in order to produce their effect, and *vice versa*.

A poison applied to a wounded surface may be supposed to act on the brain in one of three ways.

1. By means of the nerves, like poisons taken internally.

2. By passing into the circulation through the absorbent vessels.

3. By passing directly into the circulation through the divided veins.

Exp. 25.—In order to ascertain whether the woorara acts through the medium of the nerves, I exposed the axilla of a rabbit, and divided the spinal nerves supplying the upper extremity, just before they unite to form the axillary plexus. The operation was performed with the greatest care. I not only divided every nervous filament, however small, which I could detect, but every portion of cellular membrane in the axilla, so that the artery and vein were left entirely insulated. I then made two wounds in the fore-arm, and inserted into them some of the woorara formed into a paste. Fourteen minutes after the poison was applied, the hind legs became paralytic, and in ten minutes more he died, with symptoms precisely similar to those which took place in the former experiments, and the heart continued to act after apparent death. On dissection, the nerves of the upper extremity were particularly examined, but not the smallest filament could be found undivided.

I made the following experiment, to ascertain whether the woorara passes into the circulation through the absorbent vessels.

Exp. 26.—I tied a ligature round the thoracic duct of a dog, just before it perforates the angle of the left subclavian, and jugular veins. I then made two wounds in the left hind leg, and introduced some of the woorara in powder into them. In less than a quarter of an hour he became affected with the usual symptoms, and died in a few minutes afterwards.

After death, I dissected the thoracic duct with great care. I found it to have been perfectly secured by the ligature. It was very much distended with chyle; and about two inches below its termination its coats had given way, and chyle was extravasated into the cellular membrane. The lymphatic vessels in the left axilla were distended in a very remarkable degree; and on dividing them, not less than a drachm of lymph issued from the divided ends.

Since neither the division of the nerves nor the obstruction of the thoracic duct interfere in the slightest degree with the effects of the woorara, there is presumptive evidence that it acts on the brain by entering the circulation through the divided veins. I endeavoured to ascertain, by experiment, whether this is really the case.

To apply ligatures to the large vessels of a limb

POISON.

only would evidently lead to no satisfactory conclusion, since the anastomosing vessels might still carry on the circulation. The only way which I could devise of performing the experiment was to include all the vessels, small as well as large, in a ligature.

Exp. 27.—In order to make the experiment more satisfactorily, I exposed the sciatic nerve of a rabbit in the upper and posterior part of the thigh, and passed under it a tape half an inch wide. I then made a wound in the leg, and having introduced into it some of the woorara mixed with water, I tied the tape moderately tight on the fore-part of the thigh. Thus I interrupted the communication between the wounds and the other parts of the body, by means of the vessels, while that by means of the nerve still remained. After the ligature was tightened, I applied the woorara a second time, in another part of the leg. The rabbit was not at all affected, and at the end of an hour I removed the ligature. Being engaged in some other pursuit, I did not watch the animal so closely as I should otherwise have done; but twenty minutes after the ligature was removed, I found him lying on one side motionless and insensible, evidently under the influence of the poison; but the symptoms were less violent than in most instances, and after lying in this state he recovered, and the limb became perfectly warm, and he regained the power of using it.

Exp. 28.—I repeated the last experiment with this difference, that after having applied the poison, I made the ligature as tight as I could draw it. I removed the ligature at the end of an hour and twenty minutes, but the animal was not at all affected either before or after the removal of the ligature, and on the following day he had recovered the use of the limb.

Exp. 29.—I repeated the experiment a third time, drawing the ligature very tight. At the end of forty-five minutes the animal continued perfectly well, and the ligature was removed. I watched him for three quarters of an hour afterwards, but there were no symptoms of his being affected by the poison. On the following day the rabbit died; but this I attribute to the injury done to the limb and sciatic nerve by the ligature, as there was the appearance of inflammation in the parts in the neighbourhood of the ligature.

These three experiments were made with the greatest care. From the mode in which the poison was applied, from the quantity employed, and from my prior experience, I should have entertained not the smallest doubt of the poison taking effect in every instance in less than twenty minutes, if no ligature had been applied. In two of the three, the quantity of woorara was more than had been used in any former experiments.

I have not judged it necessary to make any more experiments, with the ligature on the limb, because the numerous experiments of the Abbé Fontana on the ticunas, coincide in their results with those which have just been detailed, and fully establish the efficacy of the ligature in preventing the action of the poison. It is not to be wondered at, that the ligature should sometimes fail in its effects, since these must evidently depend on the degree in which the circulation is obstructed, and on the length of time during which the obstruction is continued.

There can be little doubt that the woorara affects the brain, by passing into the circulation through the divided vessels. It is probable that it does not produce its effects until it enters the substance

of the brain, along with the blood, in which it is dissolved; nor will the experiments of the Abbé Fontana, in which he found the ticunas produce almost instant death when injected into the jugular vein of a rabbit, be found to militate against this conclusion, when we consider how short is the distance, which, in so small an animal, the blood has to pass from the jugular vein to the carotid artery, and the great rapidity of the circulation; since in a rabbit under the influence of terror, during such an experiment, the heart cannot be supposed to act so seldom as three times in a second.

I have made no experiments to ascertain through what medium other poisons when applied to wounds affect the vital organs, but from analogy we may suppose that they enter the circulation through the divided blood-vessels.

The facts already related led me to conclude that alcohol, the essential oil of almonds, the juice of aconite, the oil of tobacco, and the woorara, occasion death simply by destroying the functions of the brain. The following experiment appears fully to establish the truth of this conclusion.

Exp. 30.—The temperature of the room being 58° of Fahrenheit's thermometer, I made two wounds in the side of a rabbit, and applied to them some of the woorara in the form of paste. In seven minutes after the application, the hind legs were paralysed, and in fifteen minutes respiration had ceased, and he was apparently dead. Two minutes afterwards the heart was still beating, and a tube was introduced through an opening into the trachea, by means of which the lungs were inflated. The artificial respiration was made regularly about thirty-six times in a minute.

At first, the heart contracted one hundred times in a minute.

At the end of forty minutes, the pulse had risen to one hundred and twenty in a minute.

At the end of an hour, it had risen to one hundred and forty in a minute.

At the end of an hour and twenty-three minutes, the pulse had fallen to a hundred, and the artificial respiration was discontinued.

At the commencement of the experiment, the ball of a thermometer being placed in the rectum, the quicksilver rose to one hundred degrees; at the close of the experiment it had fallen to eighty and a half.

During the continuance of the artificial respiration, the blood in the femoral artery was of a florid red, and that in the femoral vein of a dark colour, as usual.

It has been observed by M. Bichat, that the immediate cause of death, when it takes place suddenly, must be the cessation of the functions of the heart, the brain, or the lungs. This observation may be extended to death under all circumstances. The stomach, the liver, the kidneys, and many other organs, are necessary to life, but their constant action is not necessary; and the cessation of their functions cannot therefore be the immediate cause of death. As in this case the action of the heart had never ceased; as the circulation of the blood was kept up by artificial respiration for more than an hour and twenty minutes after the poison had produced its full effects; and as during this time the usual changes in the colour of the blood took place in the lungs; it is evident that the functions of the heart and lungs were unimpaired: but that those of the brain had ceased, is proved by the animal having continued in a state of complete insensibility; and by this circumstance,

that animal heat, to the generation of which I have formerly shown the influence of the brain to be necessary, was not generated.

Having learned that the circulation might be kept up by artificial respiration for a considerable time after the woorara had produced its full effects, it occurred to me that in an animal under the influence of this or of any other poison that acts in a similar manner, by continuing the artificial respiration for a sufficient length of time after natural respiration had ceased, the brain might recover from the impression which the poison had produced, and the animal might be restored to life. In the last experiment, the animal gave no sign of returning sensibility; but it is to be observed, 1. That the quantity of the poison employed was very large. 2. That there was a great loss of animal heat, in consequence of the temperature of the room being much below the natural temperature of the animal, which could not therefore be considered under such favourable circumstances as to recovery, as if it had been kept in a higher temperature. 3. That the circulation was still vigorous when I left off inflating the lungs, and therefore it cannot be known what would have been the result, if the artificial respiration had been longer continued.

Exp. 31.—A wound was made in the side of a rabbit, and one drop of the essential oil of almonds was inserted into it, and immediately the animal was placed in a temperature of 90°. In two minutes he was under the influence of the poison. The usual symptoms took place, and in three minutes more respiration had ceased, and he lay apparently dead, but the heart was still felt beating through the ribs. A tube was then introduced into one of the nostrils, and the lungs were inflated about thirty-five times in a minute. Six minutes after the commencement of artificial respiration, he moved his head and legs, and made an effort to breathe. He then was seized with convulsions, and again lay motionless, but continued to make occasional efforts to breathe. Sixteen minutes after its commencement, the artificial respiration was discontinued. He now breathed spontaneously seventy times in a minute, and moved his head and extremities. After this, he occasionally rose, and attempted to walk. In the intervals he continued in a dozing state; but from this he gradually recovered. In less than two hours he appeared perfectly well, and he continued well on the following day.

The inflating the lungs has been frequently recommended in cases of suffocation, where the cause of death is the cessation of the functions of the lungs: as far as I know, it has not been before proposed in those cases, in which the cause of death is the cessation of the functions of the brain. It is probable, that this method of treatment might be employed with advantage for the recovery of persons labouring under the effects of opium, and many other poisons.

III. GENERAL CONCLUSIONS.

The experiments which have been detailed lead to the following conclusions.

1. Alcohol, the essential oil of almonds, the juice of aconite, the empyreumatic oil of tobacco, and the woorara, act as poisons by simply destroying the functions of the brain; universal death taking place, because respiration is under the influence of the brain, and ceases when its functions are destroyed.

2. The infusion of tobacco when injected into the intestine, and the upas antiar when applied

to a wound, have the power of rendering the heart insensible to the stimulus of the blood, thus stopping the circulation; in other words, they occasion syncope.

3. There is reason to believe that the poisons, which in these experiments were applied internally, produce their effects through the medium of the nerves without being absorbed into the circulation.

4. When the woorara is applied to a wound, it produces its effects on the brain, by entering the circulation through the divided blood-vessels; and, from analogy, we may conclude that other poisons, when applied to wounds, operate in a similar manner.

5. When an animal is apparently dead from the influence of a poison, which acts by simply destroying the functions of the brain, it may, in some instances at least, be made to recover, if respiration is artificially produced, and continued for a certain length of time."

POISON-ASH, in botany. See **AMYRIS** and **RHUS**.

POISON-NUT, in botany. See **STRYCHNOS**.

POISON-OAK, in botany. See **RHUS**.

POISON-TREE, in botany. See **RHUS**.

To POISON. v. a. (from the noun.) 1. To infect with poison (*Roscommon*). 2. To attack, injure, or kill by poison given (*Macca-bees*). 3. To corrupt; to taint (*Shakspeare*).

POISONER. s. (from *poison*.) 1. One who poisons (*Dryden*). 2. A corrupter (*South*).

POISONOUS. a. (from *poison*.) Venomous; having the qualities of poison (*Cheyne*).

POISONOUSLY. ad. Venomously (*Sou.*).

POISONOUSNESS. s. (from *poisonous*.) The quality of being poisonous; venomousness.

POISSON (Raymond), son of a mathematician at Paris, was patronized by the duke of Crequi; but quitted the profession of a courtier for the stage. He was afterwards noticed by Lewis XIV. and died at Paris, 1690. He wrote the *Baron de la Crasse*—*The Good Soldier*, comedies of one act—*Lubin*—*The Fool of Quality*, &c.

POISSON (Paul), son of the preceding, was eminent also as a comedian. He died at St. Germain-en-Laye, 1735, aged 77. His son Philip was likewise a comedian of celebrity, who died at Paris, 1743, aged 60. He was author of six comedies, 2 vols. 12mo.

POISSONNIER (Peter Isaac), a physician of Dijon, one of the first who read chemical lectures at Paris. He was sent by the court, at the request of Elizabeth, empress of Russia, who wished for the advice of an eminent physician, and on his return he was made first physician to the army, &c. and obtained a pension of 12,000 livres. The revolution sent him with all his family into confinement; but he was restored to liberty after the fall of Robespierre, and died 1797, aged 79. He wrote treatises on the means of rendering sea water potable—on the fevers of St. Domingo—on the diseases of seamen, 2 vols. 8vo.—abridgment of anatomy, 2 vols. 12mo.

POISSY, a town of France, in the department of Seine and Oise, seated near the forest of St. Germain, 15 miles N.W. of Paris.

POITIERS, a town of France, capital of

the department of Vienne, and a bishop's see. Its population is not in proportion to its extent; for it includes a number of gardens and fields within its circuit. It has several Roman antiquities, particularly an amphitheatre, partly demolished; and a triumphal arch, which serves as a gate to the great street. Here, in 1356, Edward the black prince gained a victory over the French, taking prisoners king John and his son Philip, whom he brought to England. The principal manufactures are stockings, woollen caps, gloves, and combs. It is seated on a hill, on the river Clain, 52 miles S.W. of Tours, and 120 N. by E. of Bourdeaux. Lon. 0. 21 E. Lat. 46. 35 N.

POITOU, a late province of France, bounded on the N. by Bretagne, Anjou, and Touraine, E. by Touraine, Berry, and Marche, S. by Angoumoise, Saintonge, and Aunis, and W. by the Bay of Biscay. It is fertile in corn and wine, and feeds a great number of cattle, particularly mules. It now forms the three departments of Vendée, Vienne, and Two Sevres.

POITREL. *s.* (*poictrel*, French.) 1. Armour for the breast of a horse (*Skinner*). 2. A graving tool (*Ainsworth*).

POIZE. *s.* (*poids*, French.) 1. Weight; force of any thing tending to the centre (*Spenser*). 2. Balance; equipoize; equilibrium (*Bentley*). 3. A regulating power (*Dryden*).

To POIZE. *v. a.* (*peser*, French.) 1. To balance; to hold or place in equiponderance (*Sidney*). 2. To load with weight (*Dryden*). 3. To be equiponderant to (*Shakspeare*). 4. To weigh (*South*). 5. To oppress with weight (*Shakspeare*).

POKE. *s.* (*pocca*, Saxon; *poche*, French.) A pocket; a small bag (*Drayton*).

To POKE. *v. a.* (*poka*, Swedish.) To feel in the dark; to search any thing with a long instrument (*Brown*).

POKER. *s.* (from *poke*.) The iron bar with which men stir the fire (*Swift*).

As many casualties occur from negligence, or imprudence, in leaving pokers in the fire, we shall state the following expedient, by which they may in future be prevented. It consists simply in welding or soldering a small cross of iron (projecting about an inch and a half each way), immediately above the square part of the poker called the bit. By this contrivance, the instrument cannot be thrust into the fire farther than such bit; a circumstance of some advantage, where fire-irons are highly polished. Besides, if the burning coals should yield, or any other accident happen, so as to cause the poker to slide out, it will probably be arrested on the edge of the fender. And though it should fall on the hearth or carpet, neither of these will sustain any material injury; as the heated part, or bit, will be elevated several inches above the floor.

POKING-STICK. *s.* An instrument anciently made use of to adjust the plaits of the ruffs which were then worn (*Shakspeare*).

POLA, a strong seaport of Istria, and a

bishop's see. Here are large remains of a Roman amphitheatre and a triumphal arch. It is seated on a mountain, near a bay of the gulf of Venice, 38 miles S. of Capo d'Istria. Lon. 14. 9 E. Lat. 45. 13 N.

POLACRE, a ship with three masts, usually navigated in the Levant and other parts of the Mediterranean. These vessels are generally furnished with square sails upon the main-mast, and lateen sails upon the fore-mast and mizen-mast. Some of them, however, carry square sails upon all the three masts, particularly those of Provence in France. Each of their masts is commonly formed of one piece, so that they have neither top-mast nor top-gallant-mast; neither have they any horses to their yards, because the men stand upon the top-sail-yard to loose or furl the top-gallant-sail, and on the lower-yard to reef, to loose, or furl, the top-sail, whose yard is lowered sufficiently down for that purpose.

POLAEDRASTYLA, in natural history, is the name of a genus of crystals, derived from the Greek *πολυς*, many, *εδρα*, sides, the primitive particle of *a*, not, and *στυλος*, a column; and means a crystal with many planes, and without a column.

The bodies of this genus are crystals of two octangular pyramids, with the bases joined, the whole body consisting of sixteen planes. Of this genus there are only two species known: 1. A brown kind with short pyramids, found in great plenty in Virginia on the sides of hills; and, 2. A colourless one, with longer pyramids. This has yet been found only in one place, which is the great mine at Gossalaer, in Saxony.

POLAND, a country of Europe, bounded on the N. by Prussia, Courland, Livonia, and Russia, W. by the Baltic, Brandenburg, and Silesia, S. by Hungary and Moldavia, and E. by Russia and the territories wrested by that power from the Turks. It is divided into four principal parts, Great Poland, Little Poland, Red Russia, and Lithuania; each of which is subdivided into palatinates, or provinces. Poland has now no political existence as a nation, being divided among the neighbouring states. The government was monarchical and aristocratical; all the acts of state being in the name of the king and republic of Poland. The king was the only elective sovereign in Europe; being chosen by a general diet summoned by the archbishop of Gnesna, as chief of the republic during the interregnum. This circumstance proved the source of great calamities; for, on the demise of every sovereign, the country was generally involved in a war, between contending factions, respectively supported by foreign powers. In 1772, a partition of this country, projected by the king of Prussia, was effected by that monarch, in conjunction with the empress of Russia and the emperor of Germany. By this partition, one-third of the country was wrested from the republic, the diet being compelled by a foreign force to make and to ratify this important cession. The three petitioning powers, moreover, forcibly effected a great

change in the constitution. In 1791, however, the king and the nation in concurrence almost unanimously, and without any foreign intervention, established another constitution. By this the evils of an elective monarchy were avoided, the throne being declared hereditary in the house of Saxony. The rights and privileges of all orders in the republic (the king, the nobles, the citizens, and the peasants) were alike equitably consulted; and it seemed to be formed agreeably to the universal wish of the nation. A few of the nobility, however, discontented at the generous sacrifice of some of their privileges, repaired to the court of Russia; and their representations concurring with the ambitious views of the empress, she sent an army into Poland, under pretext of being guarantee of the constitution of 1772. Her interference was too powerful to be resisted; and this new constitution was overthrown. But the principal object for which the Russian army entered Poland was not yet attained. The empress had planned, in conjunction with the king of Prussia, a second partition of this country, which took place in 1793. Such multiplied oppressions at last roused the spirit of the nation. General Kosciuszko appeared in 1794 at the head of a Polish army, to assert the independency of his country, and to recover the provinces wrested from it. He was successful at first against the king of Prussia; but was defeated, and taken prisoner in the sequel by the Russians, who soon after took the capital, Warsaw. The king formally resigned his crown at Grodno, in 1795, and was afterwards removed to Petersburg, where he remained a kind of state prisoner, till his death in 1798. The whole of the country was divided among the three partitioning powers. Austria had Little Poland, and the greatest part of Red Russia and Podolia, which is now called the kingdom of Galicia; Prussia had Great Poland, Polish Prussia, a small part of Lithuania, and Polachia; and Russia had Samogitia, the remainder of Lithuania, Volhinia, and Podolia. The towns of Poland are for the most part built with wood; and the villages consist of mean cottages, or huts. The country is so fertile in corn in many places that it supplies Sweden and Holland with large quantities, and it has extensive pastures. Peat, ochre, chalk, belemnites, agate, chalcidony, cornelians, onyxes, jasper, rock-crystals, amethysts, garnets, topazes, sapphires, and even rubies and diamonds are found in Poland; also talc, spar, lapis calaminaris, coal, iron, lead, and quicksilver. Here is much leather, fur, hemp, flax, saltpetre, alum, manna, honey, and wax; and there are mines of salt, of a great depth, out of which is dug rocksalt. Horses are numerous, very strong, swift, and beautiful; and horned cattle are bred in such numbers, that above 80,000 are driven every year out of the country. The principal rivers are the Dnieper, Vistula, Bug, Niemen, Dniester, and Bog.

POLAR. *a. (polaire, French; from pole.)* Found near the pole; lying near the pole; issuing from the pole (*Prior*).

POLAR STONE, in helminthology. See **ECHINUS**.

POLARITY, the quality of a thing considered as having poles, or a tendency to turn itself into one certain posture; but chiefly used in speaking of the magnet. See **MAGNETISM**.

POLARY. *a. (polaris, Lat.)* Tending to the pole; having a direction toward the poles (*Brown*).

POLE. *s. (pole, Saxon)* 1. A long staff (*Bacon*). 2. A tall piece of timber erected (*Shakspeare*). 3. A measure of length containing five yards and a half (*Spenser*). 4. An instrument of measuring (*Bacon*).

POLE, in astronomy, one of the extremities of the axis, on which the sphere revolves. These two points, each ninety degrees distant from the equinoctial or equator, are by way of eminence called the poles of the world; and the extremities of the axis of the artificial globes, corresponding to these points in the heavens, are termed the poles thereof. See **GLOBE**.

POLE, in geography, one of the points on which the terraqueous globe turns: each of them being 90 degrees distant from the equator, and, in consequence of their situation, the inclination of the earth's axis, and its parallelism during the annual motion of our globe round the sun, having only one day and one night throughout the year.

It is remarkable, that though the north in Hebrew, Greek, Latin, and French, derives its name from gloom, obscurity, and darkness, the poles enjoy more light than any other part of the world. The ancients believed the north to be covered with thick darkness; Strabo tells us, that Homer, by the word *σέρος*, which properly signifies obscurity or darkness, meant the north; and thus Tibullus, speaking of the north, says, *Illic et densa tellus absconditur umbra*. The Arabians call the northern ocean the dark sea; the Latins gave the name of Aquilo to the north wind, because *aquilus* signifies black; and the French call it *la bise*, from *bis*, black. According to the ancients, the Cimmerians lived in darkness, because they were placed near the north. But all this is mere prejudice; for there are no places in the world that enjoy light longer than the arctic and antarctic poles; and this is accounted for by considering the nature of twilight. In the torrid zone, and under the line, night immediately follows the setting of the sun, without any sensible twilight; whereas the twilight begins and continues increasing in proportion as places are distant from the equator or approach the pole. To this long twilight we must add the aurora borealis, which appears in the northern regions, Greenland, &c. in clear nights, at the beginning of the new moon, casting a light equal to that of full moon. (See Gassendi in the Life of Peyresc, book iii. and La Perere in his Account of Greenland.) There is also long moonlight at the poles during winter. (See **ASTRONOMY**.) But though there is really more light in the polar regions than elsewhere; yet owing to the

obliquity with which the rays of the sun fall upon them, and the great length of winter night, the cold is so intense, that those parts of the globe that lie near the poles have never been fully explored, though the attempt has been repeatedly made by the most celebrated navigators.

POLE, in spherics, a point equally distant from every part of the circumference of a great circle of the sphere, as the centre is a plane figure; or it is a point of ninety degrees distant from the plane of a circle, and in a line, called the axis, passing perpendicularly through the centre. The zenith and nadir are the poles of the horizon; and the poles of the equator are the same with those of the sphere.

POLES OF THE ECLIPTIC, are two points on the surface of the sphere, $23^{\circ} 30'$ distant from the poles of the world, and 90° distant from every part of the ecliptic.

POLES, in magnetics, are two points of a loadstone, corresponding to the poles of the world; the one pointing to the north, the other to the south. See **MAGNETISM**.

POLE, or **POLAR STAR**, is a star of the second magnitude, the last in the tail of ursa minor. Its longitude Mr. Flamsteed makes $24^{\circ} 14' 41''$; its latitude, $66^{\circ} 4' 11''$. The nearness of this star to the pole, whence it happens that it never sets, renders it of vast service in navigation, &c. for determining the meridian line, the latitude, &c.

POLE (Reginald), a cardinal and kinsman to Henry VII. was bred at Corpus Christi college, Oxford, and made dean of Exeter. According to Camden, he was born in 1500, at Stoverton castle, in Worcestershire, and was instructed in the Carthusian monastery at Shene, near Richmond, in Surry. At twelve he became a student at Magdalen college, Oxford. His royal relation conferred several favours on him, designing to raise him to the highest dignities in the church; and after he had taken the suitable degrees, allowed him a large pension to enable him to travel into Italy. Henry the Eighth's dispute with the holy see occasioned Pole to stay out of England, and to write a piece called *Pro unitate Ecclesiastica*, for which and refusing to return when ordered, his pension was taken away, and himself attainted. The pope and emperor compensated the loss of his church preferments; the former had made him cardinal in 1536, and sent him as nuncio both to France and Flanders. Under Mary he returned to England in 1554, and was made archbishop of Canterbury. He died at Lambeth palace in 1558, sixteen hours after the death of the queen. Though zealously attached to all the superstitions of his church, and to the pretensions of the papacy, he was a man of amiable manners, mild disposition, great learning, and a patron of men of letters.

To POLE. *v. a.* (from the noun.) To furnish with poles (*Mortimer*).

POLEAXE. *s.* (*pole* and *axe*.) An axe fixed to a long pole (*Howell*).

POLE-CAT, a species of weasel, partaking in some degree of the figure and propensities of

the martin and the ferret: it is smaller than the first, and considerably larger than the second; is an inhabitant of the bushy coverts in the neighbourhood of lonely farm-houses; to the poultry, eggs, and dove-houses of which they are constant and destructive enemies: The effluvia, or rather stench, arising from their bodies is so truly offensive, that it has long since laid the foundation of the well-known proverbial expression of "stinking like a pole-cat." See **MUSTELA**.

PÖLEDAVVY. *s.* A sort of coarse cloth.

POLEMICAL. **POLE'MIC**. *a.* (*πολεμικος*.) Controversial; disputative (*South*).

POLEMIC. *s.* Disputant; controvertist (*Pope*).

POLEMONIUM. Greek valerian. Jacob's ladder. Calyx five-parted; stamens standing on five valves closing the bottom of the tube; stigma three-cleft; capsule three-celled, superior. Five species; one of our own mountains, the rest natives of the Cape, or of America. The two following are cultivated:

1. *P. cœruleum*. Common polemonium, or Greek valerian. Leaves pinnate; flowers erect; calyx longer than the tube of the corol; corol blue, between bell and wheel-shaped. Found wild on our mountains. There is a variety with woolly calyxes.

2. *P. reptans*. Creeping polemonium. Leaves pinnate, with seven leaflets; flowers light-blue, terminal, nodding. A native of Virginia. Both may be increased by seeds, or parting the roots.

POLEMSCOPE, in optics, a kind of reflecting perspective glass invented by Hevelius, who commends it as useful in sieges, &c. for discovering what the enemy is doing, while the spectator lies hid behind an obstacle.

POLENBERG (Cornelius), a Dutch painter, born at Utrecht in 1586. His best pieces are of the cabinet size, as he could not rise to the execution of large figures. Being invited by Charles I. he came over to England, and though greatly encouraged, he chose to return to his native country, where he died in 1660.

POLERON. See **POOLORON**.

POLESIA, a name given to the palatinate of Brzescia, in Lithuania.

POLESINO-DI-ROVIGO, a province of Italy, in the republic of Venice; bounded on the N. by the Paduan, on the S. by the Ferrarese, on the E. by the Dogado, and on the W. by the Veronese. It is 42 miles long and 17 broad, and is fertile in corn and pastures. Rovigo is the capital.

POLETÆ were ten magistrates of Athens, who, with three that had the management of money allowed for public shows, were empowered to let out the tribute-money and other public revenues, and to sell confiscated estates; all which bargains were ratified by their president, or in his name. They were by their office also bound to convict such as had not paid the tribute called *μεσιςιον*, and sell them in the market by auction. The market where these wretches were sold was called *πωλησιον τι μεσιςιον*.

POLICANDRO, an island in the Archi-

pelago, one of the Cyclades, 20 miles in circumference. Here are a few villages, a castle, and a harbour; but it consists in general of barren rocks and mountains. It lies between Milo and Paros. Lon. 25. 31 E. Lat. 36. 32 N.

POLICASTRO, a decayed town of Naples, in Principato Citeriore, with a bishop's see. It is seated on a gulf of the same name, 68 miles S.E. of Naples. Lon. 15. 40 E. Lat. 40. 15 N.

POLICE. *s.* (French.) The regulation and government of a city or country, so far as regards the inhabitants.

POLICED. *a.* (from *police*.) Regulated; formed into a regular course of administration (*Bacon*).

POLICY. *s.* (πολιτια; *politia*, Latin.) 1. The art of government, chiefly with respect to foreign powers. 2. Art; prudence; management of affairs; stratagem (*Shakspeare*). 3. (*poliça*, Spanish.) A warrant for money in the public funds; a ticket.

POLICY OF INSURANCE, or ASSURANCE OF SHIPS, is a contract or convention whereby a person takes upon himself the risks of a sea-voyage, obliging himself to make good the losses and damages that may befall the vessel, its equipage, tackle, victualling, lading, &c. either from tempests, shipwrecks, pirates, fire, war, reprisals, in part or in whole; in consideration of a certain sum of seven, eight, or ten per cent. more or less according to the risk run; which sum is paid down to the assurer by the assured upon his signing the policy. See **INSURANCE**.

POLIDORO DA CARAVAGGIO, an Italian painter, so called from the name of a village in the duchy of Milan, in which he was born in 1495. He was a day-labourer at the Vatican, and prepared stucco for the painters, but having solicited them to teach him the rules of designing, he made such a rapid improvement that he became superior to any in the Roman school, at least in chiaro scuro. Few of the public buildings of Rome are without some of his pieces. He was most basely assassinated in 1543, by his valet, for the sake of his money.

POLIGNAC (Melchior de), a cardinal of France, born of an ancient family at Puy in 1662. His professor instructed him in the system of Aristotle, but he embraced the new doctrines of Des Cartes. He was sent by Louis XIV. as ambassador extraordinary to Poland, where, after the death of Sobieski, he formed a project of obtaining the succession for the prince of Conti. He was plenipotentiary during the congress at Utrecht, at which time Clement XI. created him a cardinal; Louis XV. chose him for his minister at Rome, where he resided till 1732. He died in 1741, leaving behind him a Latin poem in MS. called *Anti-Lucretius*, seu de Deo et Natura, a work suggested by a conversation between the author and Mr. Bayle in Holland, and printed in 1749.

POLIGNANO, a populous town of Naples, in Terra di Bari, with a bishop's see.

It is seated on a craggy rock, near the sea, 16 miles E. of Bari. Lon. 17. 24 E. Lat. 41. 25 N.

POLIGNI, a town of France, in the department of Jura, seated on a rivulet, 32 miles S.W. of Besançon. Lon. 5. 55 E. Lat. 46. 50 N.

POLINA, an ancient town of Albania, with a Greek archbishop's see. It was formerly a considerable place, but is now almost in ruins, and is 12 miles S. of Durazzo. Lon. 19. 20 E. Lat. 41. 42 N.

POLINGHERA, a town of Piedmont, situated on the Po, 13 miles S. of Turin. Lon. 7. 45 E. Lat. 44. 52 N.

POLIOSIS. (from πολιος, white.) Greyhead-
edness.

To POLISH. *v. a.* (*polio*, Lat. *polir*, Fr.) 1. To smooth; to brighten by attrition; to gloss (*Granville*). 2. To make elegant of manners (*Milton*).

To POLISH. *v. n.* To answer to the act of polishing; to receive a gloss (*Bacon*).

POLISH. *s.* (*poli*, *polissure*, French.) 1. Artificial gloss; brightness given by attrition (*Newton*). 2. Elegance of manners (*Addison*).

POLISH GAME, or POLISH DRAUGHTS. From the original, or common game of draughts, which is played upon a table containing 64 squares, and with 24 men, half white, and half black, this game differs in being played upon a table containing 100 squares, and with 40 men; and also in the increased powers it gives to the men and to the kings. In the original game a man moves, and can take forward only, and a king moves from square to square, and takes only the adversary's piece or pieces near him: in the new game, a man, in addition, takes backwards, and a king moves to any square in the line, and takes the adversary's pieces near, or far from him; all which is according to certain rules which we shall explain and exemplify from Mr. Pohlman's abridgment and translation of M. Manoury's highly esteemed French treatise upon this game; this able and accurate translator having allowed us the use of his book for the present purpose.

The origin of the Polish game of draughts does not appear to have been very decidedly ascertained; but it is supposed by M. Manoury to have commenced at Paris, in the year 1720 or 1721; and is by him attributed to two players, who were extremely skilled in the original game; one of them a French officer, and the other a Polish nobleman; whence the title of the new game may be ascribed to French courtesy, especially as it was not known in Poland for many years subsequently. The circumstance is thus related:—

“A French officer of rank, who then belonged to the regent's establishment, was frequently in the habit of playing the original game of draughts, at his apartments in the palace royal, with a Polish nobleman. One day as they were playing together, there appeared in their game a particular situation, which gave rise to an observation from the officer; he pointed out to the nobleman a fine stroke which might be made, if the laws of the game allowed the men to take backwards, like the kings. The Polish nobleman, after an attentive examination, coincided with his friend; but observed, in his turn, how much finer a stroke might

POLISH GAME.

be made if the draught board, instead of eight lines, had ten, and instead of four black and white squares on each line, it had five; which he immediately demonstrated by sketching upon a piece of paper a table suitable to the purpose. A few days afterwards the nobleman having caused a draught board to be made according to the above plan, as also forty draught men, black and white, returned with the same to his friend, and shewed him a plan he had drawn up as to the movements, and the regulations under which he proposed to establish the new game. And several meetings having been devoted to the examination and arrangement of the whole scheme, the result was the present game, which for awhile was confined to some of their mutual friends, and after some time became generally known under the title of the Polish game of draughts."

The death, in the West Indies, of a celebrated player at this game, of the name of Laclef, who was thoroughly acquainted with every thing that appertained to it, from its commencement, is adverted to by M. Manoury, as the cause which prevented the above narrative from being more complete. But for this circumstance, and the loss of his curious and scientific notes, the history, it is added, would have been perfect, and the game much better illustrated. At present M. Manoury's treatise is considered as the constitution of the Polish game, in the same manner as the work published by M. Pierre Mallet, French royal engineer, and professor of mathematics, in 1668, is that of the original game of draughts.

It is related by M. Manoury, that among the earliest players who were seen to play publicly at the Polish game, was a descendant of the celebrated traveller, Tavernier of Geneva, who played at the coffee-house, Café du Commerce, Place Dauphine, in 1727. About the same period this game began to be played also at the Hotel de Soissons, at the Café de l'Opera, Rue St. Honoré, Quai de l'Ecole, and at some other public places at Paris, while the old game gradually disappeared.

From its greater variety, the Polish game of draughts has long been, and continues to be played in preference to the old game, throughout France, and also in most other parts of the continent. As a game in which chance has no concern, it stands next to chess, and is readily embraced by persons who find the old game of draughts too limited, and the game of chess demanding too much study.

Of great players at the Polish game of draughts, M. Manoury instances the before-mentioned Laclef as a wonderful proficient; for though less distinguished for brilliancy of strokes than Marchand, another player of celebrity, he was more shrewd and acute in seasonably exchanging man for man, gaining advantage of situation and move, and straitening, perplexing, and out-manceuvring his adversary. M. Manoury, who kept a coffee-house which was frequented by skilful players, enraptured as he appears to have been with the game, was hardly inferior to either. The celebrated Philidor was partial to the game, and a good player at it; but it is said he could not stand against players of this rank; he therefore the more willingly devoted all his attention to chess.

To explain the mode in which the Polish game of draughts is played, we shall suppose the reader to have before him a square board or piece of paper, divided into 100 square spaces by means of ten parallel lines at equal distances in one direction, intersecting ten parallel lines at equal

distances in the other; these square spaces being painted alternately black and white as in common draughts: the upper line beginning with a black and closing with a white space, and every white space being numbered in succession, 1, 2, 3, 4, 5, for the first line, 6, 7, 8, 9, 10 for the second, and so on in succession to the last space in the tenth line which will have the number of 50: the first number or 1 being the first white space on the left hand of the uppermost line, and the last number or 50 being the last white space on the lowermost.

This being premised and provided for, the rules he is then to attend to are as follows, the cases being all drawn up in reference to the different squares numbered as now directed.

1. The table, or draught board containing 100 squares, 50 of which are white, and 50 black, is placed with an upper white corner towards the right hand; 20 white men and 20 black men are then placed on the white squares in opposite directions, which white squares are those numbered 1 to 20, and 31 to 50.

2. Each player plays alternately.

3. A man moves obliquely forward one square at a time, viz. from one white square to another white square; and having one or more pieces to take, he moves over two, four, six, or more squares, according to the number of pieces that are in a situation to be taken, and he may, in such case, move backwards.

4. A piece is in a situation to be taken if it stand immediately close to an adversary's man, provided there be an empty square next to the piece; in which case the adversary's man takes the piece, after placing his own man upon the empty square.

5. In like manner, if there be several pieces in such a situation, having respectively between each a vacant square, the adversary's man takes over all of them, and places himself on the last vacant square.

6. But he is not to take off any of the captive pieces until he has rested upon the last square, as far as he can go.

7. Neither can a man nor a king, in the execution of a stroke, move more than once over any of the captured pieces.

8. If by oversight or otherwise, any of the captured pieces be not taken off, but be left on the board, there is not only no redress for your not having taken off as many as you ought, but the capturing piece itself becomes forfeited, or, as it is commonly called, huffed, at the option, however, of the adversary. The act of huffing is not reckoned as a move.

9. You may decline huffing an adversary's piece, and compel him to take; and you may delay doing either.

10. If several of the adversary's pieces happen to be in situations to be taken by one or more of your pieces, it is necessary that you do take in the direction which secures most captives, taking preferably a king to a man. The adversary has the option to compel you to do this, or subject you to forfeit the man or king with which you should have taken.

11. When a man is arrived on any of the five squares in the lines which confer the right of being crowned, another of his own colour is placed upon him, and the compound piece is then called a king.

12. The lines which confer this right contain the squares numbered 1, 2, 3, 4, 5, and those

POLISH GAME

numbered 46, 47, 48, 49, 50; so that if the white men be placed on and play from the squares 31 to 50, they go to king on 1, 2, 3, 4, 5; and the black men consequently on 46, 47, 48, 49, 50.

13. If in the course of taking his adversaries, a man happens only to pass on one or more of the squares in these lines, without dwelling thereon, he is not therefore to be crowned, as this is lawful only in the event of the stroke terminating, or leaving him upon or in possession of one of these squares.

14. A king is not confined to move from square to square, but may move from one end of an oblique line to another, if the passage be free; that is, if there be none of his own colour in the way, nor of the adversaries, provided such adversaries are not in a situation to be taken. And the king having adversaries to take, may at once traverse over several squares, provided those squares are empty; or over squares occupied by the adversary's pieces, if those pieces are in a situation to be taken; so that a king often turns to the right and to the left, and makes almost the whole range of the board.

15. When, towards the conclusion of the game, two equal players happen to be left, the one with three kings, and the other with one king only on the board; if the single king be upon the centre diagonal line, and there be no immediate stroke in view, the game, after one or two moves, should be relinquished, and considered as a drawn game (as courtesy, in this case, requires that the player who has the three kings should not avail himself of the 20 moves described in next article).

16. But if the single king do not occupy the said centre diagonal line, as there are, in consequence, several schemes whereby the three kings may succeed in entrapping him; it is usual to grant for this purpose to the player who has the three kings, to play on till twenty moves shall have been respectively played; when, if he do not so succeed, the game is pronounced a drawn game.

17. When, towards the end of a game, it happens that only a king, against a king and two men, or two kings and one man, are remaining on the board, the player having the solitary king, may compel the adversary to have his man or men crowned on the spot, in order to lose no time in beginning to count the aforesaid twenty moves.

18. If at any time you make a false move, it depends upon the adversary whether it shall be recalled.

19. If you touch a piece, unless for the sake of arranging the pieces, the adversary may compel you to play it if it can be played.

EXAMPLES EXPLANATORY OF SOME OF THE FOREGOING RULES.

I. Situations explanatory of rules 3, 4, 5, 6, 8.

White, 29, 31, 38, 39, 43, 48.

Black, 11, 12, 14, 22, 32, 15.

According to the 3d rule, the white man 38, moves over several squares in taking the black men, 32, 22, 12, and 11, moving backwards in taking No. 11.

According to 4th and 5th rules, the white man 38, takes the black men 32, 22, 12, and 11, because there is between each an empty square, and places himself upon the square 16, as being the last empty square.

According to rule 6th, the player who has the white men does not take off the black men, until his man is placed and rested on the square 16, and

he does not begin to place his man 38 on square 16, and then take off the black man 32, nor continue to place his man on the square 18, and then take off the black man 22, and so on.

According to rule 8th, supposing the player who has the white, after having placed his man on the square 16, happens to take off only some of the black men, leaving, for instance, on the board, the black man 12, or even also the black man 32, he cannot, without the consent of the other player, take the men so left; and if the other player do not consent, not only must these two men remain on the board, but the player of the black men has a right to forfeit by taking off the board the white man 38, for not taking off as many as he ought; and it is to be observed, that one player can always force, if he pleases, the other to play correctly.

II. Explanatory of rule 7.

White, 27, 32, 33, 37, men—43, a king.

Black, 3, 4, 9, 19, men—10, 13, kings.

The white man 27 moves to 22. The black king 13, who has four pieces to take, is obliged to place himself on the square 28, because he is stopped by the white man 32, which cannot be taken off till the king has so placed himself. So that the white man 32, who is, in consequence, immediately behind the black king 13, now placed on 28, takes him, and also two pieces, and goes to king on square 5.

III. Explanatory of rule 10.

White, 31, 35, 38, 42, 43, 48.

Black, 5, 14, 20, 21, 22, 23, 30, 32.

Here there are several black men in a situation to be taken; but the white man 38, is obliged, and may be compelled to take the black men 32, 22, and 23. But if the player of the white should happen to take only two men, either with the said man 38, or with 35; the player of the black may avail himself of the oversight, and take off the board as a forfeited piece, the said white man 38.

IV. Explanatory of rule 9.

White, 36, 37, 40, 49, 50.

Black, 6, 7, 12, 27, 35.

In this situation the player of the black happening to overlook that his man 35, ought to take the white man 40, pushes his man 12 on 17. The adversary, finding it more advantageous not to make forfeiture of the black man 35, for not taking, advances his man 37 on the square 31. The player of the black now seeing his danger, wishes to advance his man 17 on 22, but is prevented by the player of the white, who now compels the black man 35, to take the white man 40.

V. Explanatory of rule 10.

White, 31, 35, 38, 39, 43, 48, 49.

Black, 3, 5, 9, 20, 22, 30, men—32, a king.

The white having here to take, in one direction, a king and a man, and in the other two men, are to take in the former direction, as being the stronger. If the white were to take in the latter direction, the other player might make forfeiture of the man 38; or, if it suited him better, compel the white to take as he ought to do, the black king 32, and man 22.

VI. Explanatory of rule 13.

White, 34, 42, 43.

Black, 30.

It is seen that the black man 30, in taking the white men 34 and 43, arrives on the square 48, one of the five in the line which confer the right of being crowned to the black men; but here the

POLISH GAME.

black man cannot be crowned, as he does not remain on the square 48, but is obliged to pass on to take the white man 42, in consequence of which the stroke terminates, not on 48, but on 37. And if the black man were to stop on 48, taking only the adversary's men 34 and 43, he would be forfeited.

VII. *Explanatory of rule 16.*

White, 13, 25, 41, kings.

Black, 26, a king.

In this situation there had been 19 moves played by each player. The white continue and play the 20th move, by playing the king 13 on the square 8; the black king then takes the king 13, and places himself upon the square 4; here the 20 moves respectively made by each player are completed, and the white are in consequence not at liberty to move the king 41 on 14, whereby they otherwise would win the game.

Of the odds given at the game.—It is rare to find, even among first-rate players, any two exactly equal in their play; between them there is always some shade of difference, which again daily varies according to their disposition, and particular turn existing when they sit down to play. When in one of the players there is a decided superiority, the game is to be equalized by the odds which are given to the other player. If there be but a trifling difference between two players, the odds to be given by the superior to the inferior player, usually is to allow him to reckon every other game that he may succeed to draw, as a game won. Or, he may play upon perfect equality one game, and the next game the superior player may give a man, thereby playing with 19 men against 20. The difference being greater, the superior gives up to the inferior in every game a man. And if still greater, besides giving up a man, allows a drawn game to reckon as a game won. Lastly, there being still greater disparity, the odds are extended to two men: beyond this there is no proportion or amusement to either party.

Of the drawn game.—Between equal players either at this or the original game, if they play correctly, there are games neither won nor lost, and which are therefore denominated drawn games; a drawn game arises out of that advanced stage of this game in which each player has but one, two, or three pieces left, and so situated that one player cannot prevail over the other so as to win the game, and which is therefore relinquished, withdrawn, or a drawn game. Neither at the common game at draughts, nor at chess, does there appear to be practised any fixed time to determine when a game is to be considered as drawn. Such a regulation does not appear necessary, as applicable to liberal and discerning players, because they know when to leave off; but as it is desirable to include all sorts of players, this is provided for in the rules of the present game, whereby tedious players are prevented from unnecessarily prolonging a game. To those who are acquainted with the common game only, and to those who are beginners at this, it will appear strange that when three kings against one king are the only pieces remaining on the board, the game must necessarily be a drawn game; that is, if the single king be left on the board, in a fair, open situation, not in danger, and provided no faults are made in moving him about, it shall not be possible for the three kings to capture him, or to win the game. This may be considered as an imperfection of the game, but it could not be done away without at the same time depriving the game of innumerable beauties:

against such an objection, it should further be recollected that the rights of the individual are proportionably greater than at the common game, as no adversary's king or man can, in the Polish game, pass immediately behind him with impunity, in consequence of his being allowed to take both backwards and forwards. As many tolerable players and most beginners are not aware of the schemes whereby the solitary king is frequently captured by the other three, the following situations are given.

VIII. White, 46, a king.

Black, 13, 26, 27, kings.

This is the only kind of situation in which the three kings have any chance of capturing the single king, in possession of the centre diagonal line.

If the white king whose turn it is to play were to go to the end of the diagonal line, or be placed upon the squares 10 or 14, he would be lost, because the black would give two and take him; but it is very easy to avoid this or a like stroke, by placing the king in that direction of the line from which the intended exchange cannot be made; for instance, in the present situation, the white king has four squares to make choice of, and where he will be in safety, viz. 41, 37, 28, and 23. So easy is it therefore for a king who has the command of the centre diagonal line of the board to avoid being taken by the three kings, that after one or two moves the game should be given up as a drawn game. But if the three kings are in possession, or have the command of the centre diagonal line, the game should not by them be so readily discontinued, it being very possible that before the 20 moves allowed by rule 16 are expired, the single king may fall into one or other of the snares contained in the seven following situations.

IX. White, 46, 37, 27, kings.

Black, 11, a king.

The white king 27 is placed on the square 22. The black king then takes the two white kings, and is immediately retaken. The like stroke may be performed in other directions of the board.

Of the seven situations the present one, as most easily perceived, is the least resorted to for the capture of the single king; it being hardly to be expected that when the white kings are so placed, viz. 46, 37, 27, the black king should place himself upon such a square as No. 11.

X. White, 19, 27, 37, kings.

Black, 11, a king.

The white king 27 is placed on the square 22, and the black king must take two kings, and loses the game, whether he places himself upon either of the extremities of the centre diagonal line or not: if he does not, he is immediately retaken, and if he does, the remaining white king places himself upon the opposite extremity, whereby the black king cannot afterwards move without being taken. It happens sometimes that in taking the two kings, the black king, for the purpose of deception, is placed upon the last square but one of the extremity of the line; when the player of the white, in his anxiety, imagining the black king to be upon the last square, withdraws the white king to the other extremity of the line, and who consequently becomes forfeited for not taking, and the black wins.

XI. White, 18, 26, 28, kings.

Black, 20, a king.

The white king 18 is moved on the square 9.

POLISH GAME.

The black takes him, placing himself on the square 3. The white king 28 is then placed on 17; is taken by the black king, who is retaken by the remaining white king.

XII. White, 10, 36, 37, kings.

Black, 29, a king.

The white king 37 is placed on the square 42. The black king takes him. The white king 10 is then placed on the square 15, and the black king is locked up, or cannot move without being taken.

XIII. White, 32, 37, 41, kings.

Black, 15, a king.

The white king 41 is carried to square 47. The black retreats to square 4. The white king 32 moves on 38. The black is now lost wherever he goes; he can only go on the square 9, 13, 18, 22, or 36; if he place himself on either of the four first squares, the white king 37 is advanced on the diagonal line next to the black king, who must then take two, and be retaken by the remaining white king. And if the black king is placed on the square 36, the white 38 advances on the square 15; and as the black can play only on the diagonal line 36 and 4, the white king 37 is played on 31, which the black takes returning on the square 36. The white king then moves from 15 to 4; whereby the black king is shut up, or cannot move without being taken.

XIV. White, 1, 23, 49, kings.

Black, 17, a king.

The white king 49 moves on 44. The black takes. The white king 1 moves on square 6. The black goes on 45. The white king 6 returns on square 1, and the black must take and be retaken. Or, instead of this, the white king 23 might be placed on square 1, whereby the black king is shut up, or cannot move without being taken.

XV. White 9, 28, 35, kings.

Black, 21, a king.

The white king 9 moves on the square 25, and the black is lost wherever he goes. If he move on 26 or 12, the white king 35 moves on square 8, the black must take, placing himself on square 3. The white king 26 then moves on 14, to be taken by the black, who is afterwards retaken by the other king. If the black king move on 38, 27, or 16, the white king 25 is brought upon the square 43. The black must take, placing himself upon 49. The white king 28 then places himself on 44, to be taken by the black king, who is immediately taken.

XVI. White, 7, 35, 37, kings.

Black, 43, a king.

The white king 37 is moved on the square 48, and the black is lost wherever he goes. If the black king goes to the end of the line 49 to 16, (the white king is to be left on the square 7 to be taken) the white king 48 is moved on any square in the line 48 to 26, or on the square 30. And when the black king shall have taken the white king 7, the before-mentioned white king is given to be taken by the black king, who is immediately retaken by the remaining white king. Or, if the black king should not go to the end of the line 49 to 16, then the white king 48 must be placed on 43, to be taken by the black. Afterwards the white king 7 is placed on the square 16, by which means the black is shut up, or cannot move without being taken.

VOL. IX.

XVII. White 20, 24, 35, kings.

Black, 15, a man—46, a king.

In this situation the white win, in consequence of the black having neglected to sacrifice the black man. The black is to play, and cannot play any where without losing. If the black king move upon the square 5, the white king 20 is moved on square 14. The black must take two and be retaken. Or, if the black king move on any of the other squares in the line, the white king 24 moves on the square 30. The black then takes, and the white king takes the black man and his king. It is therefore to be observed, that when you are left with a king and a man against three kings, it is best to sacrifice the man as soon as you have the opportunity, the keeping of him being frequently the occasion of your losing a game (as in the above instance) which otherwise could only be a drawn game.

In the two following situations of a single king, against a king and three men, the game becomes a drawn game:

XVIII. White, a king in the centre diagonal line 5 to 46.

Black, 36, 31, 26, men—and a king any where.

In consequence of the white king having the command of the centre diagonal line, it is not possible for the black men to move on to king; and in their present situation, it is also impossible for them to make any stroke. This is, in consequence, decidedly a drawn game.

XIX. White, a king on the diagonal line 6 to 50.

Black, 16, 21, 26, men—a king any where except on the above line.

Here the black go to king on the line 1, 2, 3, 4, 5.

This is a drawn game, for the same reason, provided the white king be conveyed on the squares 50 and 6, when the black king goes on the squares 45 and 1.

Situations for compelling a single king to quit the centre diagonal line, in order to the opening of a passage to king for your men:

XX. White, 20, 24, 35, men—a king on 15 or 6.

XXI. 20, 24, 35, men—a king on 45.

XXII. 15, 24, 35, men—a king on 25.

XXIII. 15, 20, 24, 35, men.

And other similar situations, in consequence of which the black king must immediately quit the centre diagonal line, or be taken.

Four kings against one king must win; and the game is won immediately, if they be placed as follows:

XXIV. White, 36, 37, 46, 47, kings.

Black, a king any where.

The black king cannot escape. If he be placed on 26, then move the white king 36 on the square 31. The black must remove, and the white give two for one. If he be placed on 4 or 15, then move the white king 37 on 10, to be taken, and then place a white king opposite, either on 4 or 15, as the case may require.

Four kings against two kings must be a drawn game, unless placed in such a situation as the following:

XXV. White 3, 4, 6, 47, kings.

Black, 5, 36, kings.

The white king 3 is moved on square 17, and

L L

POLISH GAME.

the black lose. If the black king 5 move on square 46, then the white king is moved on 41.

The black king takes two kings and is retaken by the white king 6, who then is to place himself on 22, thereby obliging the other black king to take and be retaken. Or, if the black king 6 moves on any other square than 46, or the other king move, the loss is still more obvious.

Five kings occupying or having the command of the centre diagonal line, immediately prevail against two kings, who cannot escape in any situation:

XXVI. White, 27, 36, 38, 46, 47, kings.

Black, 1, 50, kings.

The white king 46 is moved either on 28 or 23; whereby the black has two to take; and the white king by whom he is retaken, places himself so as to force the other black king to take two more, and then be retaken.

Situation in which five kings readily win the game, against two kings who occupy the centre diagonal line:

XXVII. White, 3, 4, 34, 36, 45, kings.

Black, 5, 46, kings.

The black to play.

1st. If the black king 46 plays on square 37, 32, or 28, the white king 4 moves on 14. The black king then takes the two white kings, and is, as well as the other black king, retaken by the white king 45.

2d. Or, if the black king 46 be played on 19, the white king moves on 14, and is taken by the black, who is retaken by the white king 4. The black must then move on square 14, 19, 28, 32, 37, 41, or 46. On whichever he moves, the white king 36 is carried on the square 22, 13, or 9; compelling the black to quit the centre line. The player of the white may then, if necessary, gain possession of the squares 36, 37, 46, and 47, as is pointed out in situation No. 24, to take the remaining black king.

3d. Or, if the black king 5 be moved on 19, the stroke of two for two is visible.

4th. Or, if the black king 5 be moved on 28 or 32, the white king 36 goes on 41, and is taken by the black king 46. The white king 4 is then placed on 10 and taken. The white king 3 is then moved on 14, and the black take two, and are immediately after both retaken.

5th. Or, if the black king 5 be moved on 37, then the white king 4 is moved on 31, and taken by the black. The white king 36 is then placed on 41, and the black king 46 takes two, is retaken by the white king 45, who in doing so is placed on 12, to be taken by the other black king, who is again retaken by the white king 3.

Some very curious strokes, denominated, in the French Treatise, chap. viii. Coup de Repos, Lunettes, &c.

The Coup de Repos consists in this: whilst one player has several successive times to take, the other, in the intervals, moves unmolested his man into a situation to be immediately after ready to act against the enemy. This stroke occurs in the four following instances.

I. White, 23, 29, 30, 31, 34, 35, 36, 48.

Black, 5, 7, 8, 9, 10, 12, 13, 18, 22, 25, 26.

White.
From 30 to 24
48 — 42
23 — 19
29 — 23
35 — 4
4 — 15

Black.
From 26 to 37
37 — 48
48 — 30
18 — 20
13 — 24
The rest is obvious.

II. White, 26, 27, 33, 36, 37, 38, 39, 42, 43, 46, 47, 49.

Black, 2, 4, 6, 7, 8, 9, 16, 17, 18, 19, 23, 30.

White.	Black.
From 27 to 21	From 16 to 27
36 — 31	27 — 36
37 — 31	36 — 27
33 — 28	23 — 32
39 — 34	30 — 37
47 — 41	32 — 43
41 — 1	43 — 48
46 — 41	48 — 25
49 — 43	25 — 48
41 — 37	48 — 31
26 — 37	Lost.

III. White, 15, 21, 31, 32, 34, 35, 37, 42, 43, 45.

Black, 7, 12, 13, 14, 17, 19, 23, 25, 26, 44.

White.	Black.
From 43 to 39	From 44 to 33
32 — 28	23 — 41
15 — 10	26 — 48
10 — 4	48 — 30
4 — 3	17 — 26
35 — 13	12 — 17
3 — 21	26 — 17
13 — 8	17 — 22
8 — 2	7 — 12
2 — 11	22 — 27
11 — 28	The rest is seen.

IV. White, 6, a king—26, 30, 33, 34, 39, 43, 48, men.

Black, 3, 4, 5, 9, 10, 15, 17, 19, 20, 22, 25, 32, 37, men.

White.	Black.
From 48 to 42	From 3 to 48
34 — 28	22 — 44
6 — 41	48 — 39
34 — 43	25 — 34
41 — 50	Lost, if the white play correctly.

Examples of men placed in exposed situations, for the purpose of enticing the adversary to attack them; in consequence of which, similar strokes to the two undermentioned frequently occur.

I. White, 26, 27, 29, 30, 33, 34, 35, 38, 40, 42, 45.

Black, 7, 8, 12, 13, 14, 15, 18, 19, 20, 22, 23, 25.

The capture of the white man behind whom the black man 22 is placed need not be lost to the white, inasmuch as he might exchange one for one. But he, perceiving the error of the black, plays as follows:

White.	Black.
From 26 to 21	From 22 to 31
21 — 17	12 — 21
33 — 28	23 — 43
42 — 38	43 — 32
29 — 24	20 — 29
34 — 3	25 — 34
3 — 43	Lost.

POLISH GAME.

II. White, 25, 27, 28, 32, 35, 36, 37, 38, 42, 43, 45, 48, 50.

Black, 6, 7, 8, 9, 10, 12, 13, 15, 16, 18, 19, 21, 23, 26, 29.

Here the white gives two for two, whereby a man remains exposed, behind which the black immediately places a man, anxious to secure him, but this proves a sad delusion.

White.	Black.
From 27 to 22	From 18 to 27
37 — 31	26 — 37
42 — 22	12 — 18
35 — 30	18 — 27
28 — 22	27 — 18
32 — 28	23 — 32
38 — 27	21 — 32
30 — 24	29 — 20
25 — 5	Lost.

Two examples on lunettes, or two or more pieces, between which there is an empty square, and behind there are other empty squares in the line they are placed on.

III. White, 28, 34, 37, 39, 40, 48.

Black, 12, 13, 14, 16, 24, 25, 27.

Here the black plays, and goes incautiously into the lunette; the white then plays from 34, to 30. The black is compelled to take four with his man 24, who then rests on 22, when the white retakes five with the man 37, and the white afterwards gets to king without any difficulty.

IV. White, 24, 25, 30, 33, 36, 43, 48, 50.

Black, 7, 13, 14, 17, 19, 26, 29, 37.

White.	Black.
From 48 to 42	From 37 to 28
24 — 2	Lose.

The following situations afford strokes for capturing one or more kings, who are apparently not in danger.

I. White, 27, 28, 29, 33, 35, 36, 37, 39, 46, 48, 49, men.

Black, 2, a king—3, 8, 12, 15, 16, 18, 19, 25, 26, men.

White.	Black.
From 37 to 31	From 26 to 37
46 — 41	37 — 46
39 — 34	46 — 23
27 — 22	18 — 27
29 — 7	2 — 30
35 — 2	Must lose.

II. White, 30, 31, 32, 34, 35, 36, 43, 45, 48, 49, men.

Black, 11, a king—I, 4, 5, 6, 8, 10, 15, 20, men.

White.	Black.
From 49 to 44	From 11 to 50
43 — 39	50 — 26
48 — 42	26 — 48
30 — 25	48 — 30
25 — 14	10 — 19
35 — 2	Have lost.

III. White, 28, 29, 32, 33, 37, 43, men.

Black, 9, 10, 46, kings—30, a man.

White.	Black.
From 29 to 24	From 30 to 19
28 — 22	Takes 9 — 28

Where he must remain, being stopped by the white 32, over whom he cannot again pass. (See rules 6 and 7).

32 — 5
Shut up.

IV. White, 19, 25, 26, 35, 36, 39, 42, 44, 45, 47, 50, men.

Black, 3, 12, 22, 27, kings—4, 5, 10, 15, men.

This situation and subsequent stroke, M. Mounoury does not vouch for as having actually occurred at play; he candidly supposes the same to have been composed: but it evidently must have been done by a good player, and shews that this game is susceptible of great ingenuity.

White.	Black.
From 19 to 13	From 22 to 9
39 — 34	12 — 49
36 — 31	27 — 36
26 — 21	3 — 48
47 — 41	36 — 47
50 — 44	49 — 40
45 — 34	48 — 30
35 — 24	47 — 20
25 — 3	Can no longer play.

Different situations in which brilliant and well-calculated strokes have occurred.

I. White, 17, 22, 23, 27, 31, 33, 36, 37, 38, 40, 44, 50.

Black, 1, 5, 6, 7, 8, 9, 10, 13, 20, 25, 26, 30

This situation occurred at a game played with the celebrated player, Marchand, who had the white men, and played as follows:

White.	Black.
From 23 to 19	From 13 to 24
33 — 29	24 — 42
37 — 48	26 — 37
17 — 11	6 — 28
36 — 31	37 — 26
27 — 21	26 — 17
40 — 34	30 — 39
44 — 24	Lost.

II. White, 26, 27, 28, 29, 31, 32, 33, 35, 36, 37, 38, 39, 40, 42, 43, 45, 49.

Black, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 18, 19, 22.

White.	Black.
From 29 to 23	From 18 to 29
33 — 24	22 — 44
35 — 30	44 — 35
27 — 22	17 — 28
32 — 5	Lose.

III. White, 25, 26, 27, 28, 30, 31, 32, 33, 35, 36, 37, 40, 41, 45, 48.

Black, 6, 7, 8, 9, 11, 13, 14, 15, 16, 17, 18, 19, 21, 23, 24.

This is a very fine, and well-calculated stroke.

White.	Black.
From 23 to 20	From 14 to 34
40 — 20	15 — 24
35 — 30	24 — 35
45 — 40	35 — 44
33 — 29	23 — 34
28 — 22	17 — 28
32 — 1	21 — 32
1 — 27	Lost.

IV. White, 27, 28, 32, 33, 35, 36, 38, 39, 40, 42, 43, 44, 45, 48.

Black, 3, 6, 7, 8, 9, 12, 13, 14, 16, 17, 18, 19, 23, 24, 26.

White.	Black.
From 39 to 30	From 32 to 49
30 — 35	Lost every where.

Our limits will not allow us to select a greater number of curious situations. Those who are desirous of pursuing them farther must consult Mr. Polhman's work, which extends them to upwards of a hundred.

POLISHABLE. *a.* (from *polish*.) Capable of being polished.

POLISHER, or BURNISHER, among mechanics, an instrument for polishing and burnishing things proper to take a polish. The gilders use an iron-polisher to prepare their metals before gilding, and the blood-stone to give them the bright polish after gilding. The polishers, among cutlers, are a kind of wooden wheels made of walnut-tree, about an inch thick, and of a diameter at pleasure, which are turned round by a great wheel; upon these they smooth and polish their work with emery and putty. The polishers for glass consist of two pieces of wood; the one flat, covered with old hat: the other long and half-round, fastened on the former, whose edge it exceeds on both sides by some inches, which serves the workmen to take hold of, and to work backwards and forwards by. The polishers used by spectacle-makers are pieces of wood a foot long, seven or eight inches broad, and an inch and a half thick; covered with old beaver hat, whereon they polish the shell and horn frames their spectacle-glasses are to be set in.

POLISHING, in general, the operation of

giving a gloss or lustre to certain substances, as metals, glass, marble, &c.

The operation of polishing optic-glasses, after being perfectly ground, is one of the most difficult points of the whole process. Before the polishing is begun, it is proper to stretch an even well-wrought piece of linen over the tool, dusting upon it some very fine tripoli. Then taking the glass in your hand, run it round forty or fifty times upon the tool, to take off the roughness of the glass about the border of it. This cloth is then to be removed, and the glass to be polished upon the naked tool, with a compound powder made of four parts tripoli mixed with one of fine blue vitriol; six or eight grains of which mixture are sufficient for a glass five inches broad. This powder must be wetted with eight or ten drops of clear vinegar, in the middle of the tool; being first mixed and softened thoroughly with a very fine small mullet. Then with a nice brush, having spread this mixture thinly and equably upon the tool, take some very fine tripoli, and strew it thinly and equably upon the tool so prepared, after which, take the glass to be polished, wiped very clean, and apply it on the tool, and move it gently twice or thrice in a straight line backwards and forwards; then take it off, and observe whether the marks of the tripoli, sticking to the glass, are equably spread over the whole surface; if not, it is a sign that either the tool or glass is too warm, in which case you must wait awhile and try again, till you find the glass takes the tripoli every where alike. Then you may begin to polish boldly, there being no danger of spoiling the figure of the glass, which in the other case would infallibly happen. This is Mr. Huygens's method; but it ought to be observed, that almost every operator has a peculiar one of his own, and of which some of them make a mighty secret.

Sir Isaac Newton nowhere expressly describes his method of polishing optical glasses; but his method of polishing reflecting metals he thus describes in his Optics. He had two round copper plates, each six inches in diameter, the one convex, the other concave, ground very true to one another. On the convex one he ground the object-metal; or concave which was to be polished, till it had taken the figure of the convex, and was ready for a polish. He then pitched over the convex very thinly, by dropping melted pitch upon it, and warming it to keep the pitch soft, whilst he ground it with the concave copper wetted, to make it spread evenly all over the convex, till it was no thicker than a groat-piece; and after the convex was cold he ground it again, to give it as true a figure as possible. He then ground it with very fine putty, till it made no noise; and then upon the pitch he ground the object-metal with a brisk motion for two or three minutes; when laying fresh putty upon the pitch, he ground it again till it had done making a noise, and afterwards ground the object-metal upon the pitch as before; and this operation he repeated till the metal was perfectly polished.

For other ingenious methods of grinding and polishing lenses and specula, see Brewster's edition of Ferguson's Lectures, vol. ii. p. 452—461.

POLITE. *a.* (*politus*, Latin.) 1. Glossy; smooth (*Newton*). 2. Elegant of manners (*Pope*).

POLITELY. *ad.* (from *polite*.) With elegance of manners; genteelly.

POLITENESS. *s.* (*politesse*, Fr.) Elegance of manners; gentility; good breeding (*Swift*).

POLITIANO (Angelo), an ingenious Italian, born 1454, at Monte Pulciano, in Tuscany. He learnt Greek under Andronicus of Thessalonica, and studied philosophy under Ficinus and Argyropylus. He was noticed by the Medicean family, and was for some time preceptor to Lorenzo's children, and afterwards professor of Greek and Latin at Florence. He was the intimate friend of the learned men of the times, and died 1494, as some say, from great grief for the misfortunes of the Medicean family, who had been expelled from their country. As a poet his lines on the tournament of Julian de Medicis are much admired. He wrote besides the history of the Pazzi conspiracy—miscellanea—some other poems, and a Latin translation of Herodian, so elegant and so spirited, that it is doubted which is the more valuable, the original or the version—a treatise on anger, &c. His works altogether were printed in 1550, 3 vols. 8vo. and 1553, folio.

POLITICAL. *a.* (*πολιτικός*.) 1. Relating to politics; relating to the administration of public affairs; civil (*Rogers*). 2. Cunning; skilful: usually in this latter sense, written *politic*.

POLITICAL ARITHMETIC, is the art of reasoning by figures upon matters relating to government, such as the revenues, number of people, extent and value of land, taxes, trade, &c. in any nation. These calculations are generally made with a view to ascertain the comparative strength, prosperity, &c. of any two or more nations.

POLITICAL ECONOMY, is the science in which the wealth of nations is considered. Its object is to ascertain, in the first place, wherein wealth consists, and then to explain the causes of its production, and the principles on which it is distributed through the different orders of society. It likewise endeavours to point out the tendency which any political regulations may have to favour or to injure the productions or most advantageous distribution of wealth. Such is its peculiar object, and consequently though writers on political economy may frequently treat on the more important topics of national security, freedom and happiness, these are then passing the strict limits of their science.

Political economy, in some of its branches, has engaged the attention of speculative men in all ages; but it is only in very recent times that the truths it exhibits have been collected, arranged, and demonstrated with such precision, as to entitle it to the name and dignity of a science.

The writers on political economy may be arranged in two great classes; the former composed of those who regard commerce, and the latter of those who regard agriculture as the principal source of national wealth. Almost all the older writers belong to the former class. The most considerable English writers of this class are Dr. d'Avenant and sir John Stewart, and their principles are interwoven in the elaborate History of Commerce, by Anderson. The decisions of the English legislature have usually been guided by the principles of these writers.

The commercial system of political economy is very perspicuously explained, and very ably examined in the fourth book of Smith on the Wealth of Nations.

The agricultural system is of comparatively recent origin. It was first brought into vogue by Mons. Quesnai, a celebrated French physician. His ideas were adopted and diffused by several very able writers, and are thought to be most clearly explained in L'Ordre Naturel de Sociétés Politiques, by Mercier de la Rivière. The writings of Quesnai have been published, with remarks and illustrations in a work entitled Physiocratie, by Dupont de Nemours. The followers of Quesnai are styled the economists. There is no English writer of celebrity by whom these principles have been adopted in their whole extent; but they are stated, and in some degree controverted, in the last chapter of the fourth book of Smith.

By far the greatest work on political economy is the treatise on the Wealth of Nations, by Adam Smith. The acuteness of later writers may have discovered some inconsiderable errors in the reasonings; may have shewn that some portions of it are not so completely finished as the rest, and that some well grounded objections may be urged against parts of its arrangement; but the most able judges unanimously regard it as a work at once original, accurate, and profound; as just in its principles, and perspicuous in its illustrations.

A striking and very important difference between the old and new systems of political economy consists in the former calling upon all occasions for the regulation and controul of laws, and regarding the legislature as best qualified to estimate the value of any particular branches of trade, or modes of conducting business; while by the latter the merchant is supposed to be the best judge of the most eligible method of conducting his own affairs. The former is a system of restrictions and encouragements in which little is left to the choice and sagacity of individuals; in the latter it is supposed that national wealth, which is the aggregate of individual wealth, will increase most rapidly, where, while private property is rendered sacred by the laws, talent and enterprise are under the least possible restraint.

POLITICALLY. *ad.* 1. With relation to public administration. 2. Artfully; politically.

POLITICASTER. *s.* A petty ignorant pretender to politics (*L'Estrange*).

POLITICIAN. *s.* (*politicien*, French.) 1. One versed in the arts of government; one skilled in politics (*Dryden*). 2. A man of artifice; one of deep contrivance (*Milton*).

POLITIC. *a.* (*πολιτικός*.) 1. Political; civil (*Temple*). 2. Prudent; versed in affairs (*Shakspeare*). 3. Artful; cunning (*Bacon*).

POLITICLY. *ad.* Artfully; cunningly (*Shakspeare*).

POLITICS. *s.* (*politique*, Fr. *πολιτική*.) The science of government; the art or practice of administering public affairs (*Addison*).

POLITURE. *s.* (*politure*, Fr.) The gloss given by the act of polishing.

POLITY. *s.* (*πολιτεία*.) A form of government; civil constitution (*Hooker*).

POLIUM. (*πολιον*, from *πολιος*, white; so called from its white capillaments.) Poley.

POLITO, or **POLIZZI**, a town of Sicily, in Val di Demona, at the foot of the mountain Madonia, 30 miles S.E. of Palermo. Lon. 13. 53 E. Lat. 38. 4 N.

POLITZ, a town of Upper Saxony, in Anterior Pomerania, near the Frisch Haff, celebrated for its hops. It is eight miles N. of Stetin.

POLL. *s.* (*polle*, *pol*, Dutch, the top.) 1. The head (*Shakspeare*). 2. A catalogue or list of persons; a register of heads or persons (*Shakspeare*). 3. A fish called generally a chub, or chevin.

To POLL. *v. n.* (from the noun.) 1. To lop the tops of trees (*Bacon*). 2. In this sense is used *polled* sheep (*Mortimer*). 3. To pull off hair from the head; to clip short; to shear (*Ezekiel*). 4. To mow; to crop (*Shakspeare*). 5. To plunder; to strip; to pill (*Bacon*). 6. To take a list or register of persons. 7. To enter one's name in a list or register (*Dryden*). 8. To insert into a number as a voter (*Tickel*).

POLL-EVIL, in farriery, a name given to an abscess formed near to the head of a horse, about the junction of the first vertebra of the neck. It commonly proceeds either from a blow or hurt received on the head, as by his accidentally striking it against the ceiling of a low stable. Mr. Denny advises, that whenever this is perceived, by a tumour forming about this part, the earliest and most active means should be employed to disperse it.

The most effectual remedy, he says, is that of anointing the inflamed parts with blistering liniment; for, by this simple treatment alone, an abscess may generally be prevented. Whenever the inflammation, however, has proceeded to suppuration, as soon as the matter can be distinctly felt, an opening must be made as near as possible to the inferior part of the abscess, to allow of a free discharge of its contents, and a seton be introduced through the whole extent of the cavity, which should be frequently moved, and washed with spirits of turpentine. The healing process may be assisted by daily injecting into the cavity of the abscess a lotion of muriated mercury with tincture of myrrh.

POLLACK, in ichthyology. See **GADUS**.
POLLARD. *s.* (from *poll*.) 1. A tree lop-

ged (*Bacon*). 2. A clipped coin (*Camden*).

3. The chub fish (*Ainsworth*).

POLLEN, in botany, farina, or prolific powder, like fine meal or flower, contained in the anther of flowers; and which, according to Linnæus, being moistened with a liquor peculiar to it, and lodged upon the stigma, bursts like a bladder, and explodes elastically a substance imperceptible to the naked eye; which he calls *fovilla*. Pollen, when exposed to the microscope, is found to put on a great variety of forms in the flowers of different plants. Thus in *helianthus* it is a prickly ball, like a burr. In *geranium* it is perforated. In *symplythum* it is twin or double. In *malva* it is a toothed wheel. In *viola* it is angular. In *narcissus* it is kidney-shaped. In *borage* it is like a roll of parchment.

POLLENGER. *s.* Brushwood.

POLLER. *s.* (from *poll.*) 1. Robber; pil-lager; plunderer (*Bacon*). 2. He who votes or polls.

POLLEX. The thumb, or great toe.

POLLIA, in botany, a genus of the class hexandria, order monogynia. Corol six-petalled, inferior, the three outer petals larger, three inner reflected; berry many-seeded. One species; an herbaceous plant of Java and Japan, with white flowers in a whorled corymb.

POLLICHIA, in botany, a genus of the class monandria, order monogynia. Calyx one-leaved, five-toothed; corol five-petalled; seed one; receptacle producing succulent scales sustaining the fruit. One species; a Cape plant with green flowers in sessile, opposite axillary clusters.

POLLIO. The most celebrated of this name is C. Asinius, a Roman consul, in the reign of Augustus, distinguished as much by his eloquence as by his military exploits. He defeated the Dalmatians, and favoured the cause of Antony against Augustus. He patronized with great liberality the poets Virgil and Horace, and was the first who raised a public library at Rome. He was with Julius Cæsar when he crossed the Rubicon, and was greatly esteemed by Augustus after the ruin of Antony. Pollio wrote some tragedies, orations, and an history, in 17 books, which are all lost, and nothing remains of his writings except a few letters to Cicero. He died in the 80th year of his age, A. D. 4. It is to him Virgil has inscribed his fourth eclogue.

To **POLLUTE**. *v. a.* (*polluo*, Lat.) 1. To make unclean, in a religious sense; to defile (*Shakspeare*). 2. To taint with guilt (*Milton*). 3. To corrupt by mixtures of ill (*Dryden*).

POLLUTEDNESS. *s.* (from *pollute*.) Defilement; the state of being polluted.

POLLUTER. *s.* (from *pollute*.) Defiler; corrupter (*Dryden*).

POLLUTION. *s.* (*pollutio*, Lat.) 1. The act of defiling (*Ayliffe*). 2. The state of being defiled; defilement.

POLLUX. See **CASTOR**.

POLLUX (Julius), a Greek writer, who flourished A. D. 186, in the reign of Commodus,

and died in the 58th year of his age. He taught rhetoric at Athens, and wrote an useful work called *Onomasticon*.

POLLUX, in astronomy, a fixed star of the second magnitude, in the constellation Gemini, or the twins. See **CASTOR** and **GEMINI**.

POLOTSK, a government of the Russian empire, formed of part of a palatinate of Lithuania, dismembered from Poland by the treaty of partition in 1772. Its products are chiefly grain, hemp, flax, and pasture; and the forests furnish great abundance of masts, planks, oak for ship-building, pitch, tar, &c. which are chiefly sent down the Dwina to Riga.

POLOTSK, a strong town of Russia, capital of a government of the same name, seated on the Dwina, at the mouth of the small river Polota, 50 miles S.W. of Vitepsk. Lon. 27. 50. E. Lat. 55. 43 N.

POLTEN (St.), a town of Lower Austria, seated on the Drasam, which falls into the Danube, near Holmburgh, eight miles from Vienne.

POLTROON, or **POLTRON**, a coward or dastard, wanting courage to perform any thing great or noble. The word is borrowed from the French, who, according to Salmasius, derive it a *pollice truncato*; because anciently those who would avoid going to the wars cut off their thumb. But Menage, with more probability, derives it from the Italian *paltron*, and that from *paltro*, a bed; because timorous, pusillanimous people take pleasure in lying a-bed. Others choose to derive the word from the Italian *paltro*, a colt; because of that creature's readiness to run away.

POLVERINE, the calcined ashes of a plant; of a similar nature with our pot-ashes or pearl-ashes. It is brought from the Levant and Syria; and in the glass-trade it is always to be preferred to any other ashes. The *barilla*, or pot-ashes of Spain, yield more pure salt than the pulverine of the Levant, but the glass made with it has always some blue tinge; that made with the pulverine is perfectly white, which ought always to be used for the finest crystal.

PO'LY. (*πολυς*.) A prefix often found in the composition of words derived from the Greek, and intimating multitude: as, *polygon*, a figure of many angles.

POLYACOUSTIC. *a.* (*πολυς* and *ακουω*.) That multiplies or magnifies sounds.

POLYADELPHIA. (*πολυς*, many, and *αδελφος*, a brother; several brotherhoods.) In botany, the name of the eighteenth class in the Linnæan system; comprehending those plants which bear herinaphrodite flowers, with three or more sets of united stamens.

POLYÆNUS, the name of many famous men recorded in ancient writers. Among them was Julius Polyænus, of whom we have some Greek epigrams extant in the first book of the *Anthologia*. The Polyænus whom it most concerns us to know about, is the author of the eight books of the *Stratagems of illustrious Commanders in War*. He was probably a Macedonian, and perhaps a soldier in the

early part of his life; but of this there is no certainty. He was undoubtedly a rhetorician and a pleader of causes; and appears, from the dedication of his work to the emperors Antoninus and Verus, to have lived towards the latter part of the second century. The *Stratagemata* were published in Greek by Isaac Casaubon, with notes, in 1589, 12mo; but no good edition of them appeared till that of Leyden, 1690, in 8vo. The title-page runs thus: Polyæni Stratagematum libri octo, Justo Vulteo interprete, Pancratius Maasvicius recensuit, Isaaci Casauboni nec non suas notas adiecit. This is indeed a very elegant edition, in which the notes of Casaubon and Maasvicius accompany each page.

POLYÆMIA. (from πολυς, much, and αἷμα, blood.) Plethora. Redundancy of blood.

POLYANDRIA. (πολυς and ἀνὴρ, a husband.) In botany, the name of the thirteenth class in the Linnæan system, comprehending those plants which bear hermaphrodite flowers with many stamens (from twenty to a thousand) growing single on the receptacle. The number of the stamens distinguishes this from the first eleven classes; their situation (on the receptacle) separates it from the twelfth class, icosandria: and their simplicity avoids all confusion with the sixteenth and eighteenth classes, monodelphia and polyadelphia.

POLYANTHEA, a collection of common-places in alphabetical order, for the use of orators, preachers, &c. The word is formed from the Greek πολυς, much, and ἄνθος, flower; and has much the same meaning with anthology or florilege. The first author of the polyanthea was Dominic Nanni de Mirabellio, whose labour has been improved on by Barth. Amantius, and Franc. Torsius; and since these, by Jos. Langius, under the title of *Polyanthea nova*, 1613.

POLYANTHES, in botany, a genus of the class hexandria, order monogynia. Corol funnel-form, incurvated, equal; filaments inserted in the throat of the corol; germ seated in the bottom of the corol. One species only, *P. tuberosa*, an herbaceous flowering perennial of Java and Ceylon.

There are varieties with a double flower; with striped leaves; and with a smaller flower. The last is frequent in the south of France, whence the roots have been often brought here early in the spring, before the market is supplied with the same sort from Italy.

This plant, however, is chiefly cultivated by the Genoese, from whom most other countries are supplied when the roots cannot be propagated without great trouble and labour. For about Genoa, in Sicily and Spain, the roots will multiply, when once planted, with little or no attention.

In cultivating this plant it should be observed that the blowing roots, imported for sale, are mostly furnished with offsets, which should be separated previously to planting. They should be preserved in dry sand and in a dry sheltered place during winter; and in the beginning of spring, as the month of March, may be planted

out either in a bed of light dry earth in the full ground, or, if wanted in a forward state, in a moderate hot-bed; care being taken to shelter them in cold-weather, either by a frame and lights, or mats on arched hoops; the air being freely enjoyed by them in mild weather, and giving them plenty of water in dry seasons, and through the whole period of flowering.

These plants are all highly ornamental, but especially the single and double sorts, among other tender potted plants. The dwarf and variegated sorts afford also a fine and agreeable intermixture.

POLYANTHUS, in botany. See **PRIMULA**.

POLYANTHUS NARCISSUS, in botany. See **NARCISSUS**.

POLYBIUS, a famous Greek historian, was born at Megalopolis, a city of Arcadia, 205 years before Christ; and was the son of Lycortas, chief of the republic of the Achæans. He was trained to arms under the celebrated Philopœmen, and is described by Plutarch as carrying the urn of that great but unfortunate general in his funeral procession. He rose to considerable honours in his own country, but was compelled to visit Rome with other principal Achæans, who were detained there as pledges for the submission of their state. From hence he became intimate with the second Scipio Africanus, and was present with him at the demolition of Carthage. He saw Corinth also plundered by Mummius, and thence passing through the cities of Achaia, reconciled them to Rome. He extended his travels into Egypt, France, and Spain, that he might avoid such geographical errors as he has censured in others.

It was in Rome that he composed his excellent history, for the sake of which his travels were undertaken. The history was divided into 40 books; but there only remain the five first with extracts of some parts of the others. It has had several editions in Greek and Latin; and there is an English translation by Mr. Hampton. He died at the age of 82.

POLYCARDIA, in botany, a genus of the class pentandria, order monogynia. Petals five, rounded; stigma lobed; capsule five-celled, five-valved; seeds arillate. One species only; a Madagascar shrub with alternate leaves; barren ones lanceolate, fertile ones inversely heart-shaped, wedge-shaped at the base; flowers three or four at the tip of the fertile leaves.

POLYCARP, one of the most ancient fathers of the Christian church, was born towards the end of the reign of Nero, probably at Smyrna; where he was educated at the expense of Calista, a noble matron distinguished by her piety and charity. He was unquestionably a disciple of St. John the Evangelist, and conversed familiarly with others of the apostles. When of a proper age, Bucolus ordained him a deacon and catechist of his church; and upon his death he succeeded him in the bishopric, to which he is said to have been consecrated by St. John, who also directed his Apocalypse, among others, to him; under the title of the

Angel of the Church of Smyrna. At length the controversy about the observation of Easter beginning to grow high between the eastern and western churches, he went to Rome to discourse with those who were of the opposite party. The see was then possessed by Anicetus, with whom he had many conferences, that were carried on in the most peaceable and amicable manner; and though neither of them could bring the other to embrace his opinion, they both retained their own sentiments without violating that charity which is the great law of their religion.

Whilst at Rome he particularly opposed the heresies of Marcion and Valentinus. His conduct on this occasion is related by Irenæus; who informs us, that when Polycarp passed Marcion in the street without speaking, Marcion said, "Polycarp, own us!" to which he replied with indignation, "I own thee to be the first born of Satan." Irenæus adds, that when any heretical doctrines were spoken in his presence, he would stop his ears and say, "Good God! to what times hast thou reserved me, that I should hear such things!" and immediately left the place. He was wont to tell, that St. John, going into a bath at Ephesus, and finding Cerinthus the heretic in it, immediately started back without bathing, crying out, "Let us run away, lest the bath should fall upon us while Cerinthus the enemy of truth is in it." Polycarp governed the church of Smyrna with apostolic purity, till he suffered martyrdom in the 7th year of Marcus Aurelius; the 7th of the kalends of May, A. C. 167. The amphitheatre on which he suffered was mostly remaining not many years ago; and his tomb, which is in a little chapel in the side of a mountain, on the south-east of this city, was solemnly visited by the Greeks on his festival day; and for the maintenance and repairing of it, travellers were wont to throw a few aspers into an earthen pot that stands there for the purpose. He wrote some homilies and epistles, which are now lost, except that to the Philippians, which is a truly pious and Christian piece, containing short and useful precepts and rules of life, which St. Jerome informs us was even in his time read in the public assemblies of the Asiatic churches. It is singularly useful in proving the authenticity of the books of the New Testament; for he has several passages and expressions from Matthew, Luke, the Acts, St. Paul's Epistles to the Philippians, Ephesians, Galatians, Corinthians, Romans, Thessalonians, Colossians, 1st Timothy, 1st Epistle of St. John, and 1st of Peter; and makes particular mention of St. Paul's Epistle to the Ephesians. Indeed his whole epistle consists of phrases and sentiments taken from the New Testament. (Jortin's Ecclesiastical Hist. vol. i. p. 68, &c.)

POLYCARPON. All-seed. In botany, a genus of the class triandria, order trigynia. Calyx five-leaved; petals five, ovate, very small; capsule one-celled, three-valved; seeds numerous. One species, *P. tetraphyllum*, found wild on our own coasts.

POLYCHREST, in pharmacy, a medicine that serves for many uses, or that cures many disorders.

POLYCNEMON, in botany, a genus of the class triandria, order monogynia. Calyx three-leaved; petals five, calyx-like; seed one, almost naked. Five species, natives of Siberia.

POLYCOTYLEDONOUS PLANTS. Plants which have more than two cotyledons or lobes to the seed; as pinus, cupressus, linum.

POLYCRATES, a tyrant of Samos, who made himself master not only of the neighbouring islands, but also of some cities on the coast of Asia. He was so universally respected, that Amasis, king of Egypt, made a treaty of alliance with him. The Egyptian monarch, however, advised him to chequer his enjoyments, by relinquishing some of his most favourite objects. Polycrates complied, and threw into the sea a seal, the most valuable of his jewels. The voluntary loss of the seal afflicted him for some time, but a few days after he received as a present a large fish, in whose belly the jewel was found. Some time after, Polycrates visited Magnesia, where he had been invited by Orctes, the governor, who shamefully put him to death, 522 years before Christ, merely because he wished to terminate the prosperity of Polycrates.

POLYDAMAS, a Trojan, son of Antenor, by Theano. He married Lycaste, a natural daughter of Priam, and was accused of having betrayed his country to the Greeks. 2. A son of Panthous, born the same night as Hector. He was inferior to none of the Trojans, except Hector. He was at last killed by Ajax. 3. A celebrated athlete, who imitated Hercules in whatever he did. It is said that he killed a lion with his fist, and that he could stop a chariot with his hand in its most rapid course.

POLYDAMNA, the wife of Thonis, king of Egypt. She gave Helen a certain powder, which had the wonderful power of driving away care.

POLYDECTES, a king of Sparta, of the family of the Proclidæ. He was son of Eunomus. 2. A king of the island of Seriphos. He received with great kindness Danae and her son Perseus, exposed on the sea by Acrisius. (See PERSEUS.) He educated Perseus; but when he became enamoured of Danae, he removed him from his kingdom. Some time after, Danae, having rejected his addresses, fled to the altar of Minerva for protection, and Dictys, the brother of Polydectes, armed himself in her defence. At this critical moment, Perseus arrived, and with Medusa's head, turned into stones Polydectes, with the associates of his guilt.

POLYDIPSIA. (πολυδιψια, from πολυς, much, and διψη, thirst). Excessive thirst. A genus of disease in the class locales, and order dysorexia of Cullen. It is mostly symptomatic of fever, dropsy, excessive discharges, or poisons.

POLYDORE VIRGIL, of Urbino, came to England in the suit of the papal legate. He

so pleased Henry VIII. by his learning that he gave him the archdeaconry of Wells, and prevailed upon him to employ his talents in an history of the country. He afterwards left England in consequence of the conduct of Wolsey, who had imprisoned him for one year, because his patron Corneto had solicited the see of York, and he retired to Italy, where he died 1555. His works are the history of England to the end of the seventh Henry's reign, dedicated to Henry VIII. a work written in elegant Latin, but not very accurate as an history—*de inventoribus rerum*, 12mo.—treatise on prodigies, fol.—correction on Gildas, &c.

POLYDORUS. The most remarkable of this name are the following:—1. A son of Alcamenes, king of Sparta, who put an end to the war which had been carried on during 20 years, between Messenia and his subjects. He was assassinated by a nobleman, called Polemarchus, and his son Eurycrates succeeded him 724 years before Christ. 2. A son of Priam by Hecuba. As he was young when Troy was besieged by the Greeks, his father entrusted him, with the greatest part of his treasures, to Polymnestor, king of Thrace, till his country was freed from invasion. No sooner was the death of Priam known than Polymnestor made himself master of the riches, and assassinated young Polydorus, and threw his body into the sea. (See *HECUBA*.) According to Virgil, the body of Polydorus was buried near the shore, and there grew on his grave a myrtle, whose boughs dropped blood, when Æneas, going to Italy, attempted to tear them from the tree. (See *POLYMNESTOR*.)

POLYEDRICAL. **POLYEDROUS.** *a.* (from *πολυεδρῆς*; *polyedre*, Fr.) Having many sides (*Boyle*, *Woodward*).

POLYEDRON, or **POLYHEDRON**, a solid or body having many sides or faces.

POLYGALA. Milk-wort. In botany, a genus of the class diadelphia, order octandria. Calyx five-leaved, two of them wing-shaped and coloured; legume inversely heart-shaped, two-celled, two-valved. Seventy-six species scattered over the globe, which may be thus subdivided into sections.

A. Flowers with a crest or pencil-like appendage.

B. Flowers not crested; shrubby.

C. Beardless, herbaceous, with the stem quite simple.

D. Bearded, herbaceous, with the stem branched.

The following are most entitled to notice.

1. *P. vulgaris*. Common milk-wort. Found in our pastures, the root similar in taste to *P. seneka*, but much weaker. The leaves are very bitter, and a handful of them infused in wine is said to be a safe and gentle purge.

2. *P. amara*. Bitter milk-wort. Indigenous to the south of Europe, with larger leaves than the preceding. In medicine it has been freely used in phthisis; but where other resources have failed this has not been more suc-

cessful; yet as a palliative it claims attention. Its virtues are balsamic, demulcent, corroborant.

3. *P. Senega*. Rattlesnake-root. A North American plant, with woody, branched, twisted root; stems simple, erect, slender, glabrous, reddish; leaves alternate; flowers white. This was formerly supposed to be an antidote against the bite of the rattlesnake; whence its specific name: it is now used for other medical purposes, for which see the article *SENEGA*.

The two following are cultivated in our gardens.

4. *P. myrtifolia*. Myrtle-leaved milk-wort: with shrubby stem, four or five feet high; leaves oblong, obtuse, glabrous; racemes terminal, few-flowered; flowers crested, large, white without, purple within; keel of the corol falcate. A native of the Cape.

5. *P. chamæbuxus*. Box-leaved milk-wort. Slender branching woody stalk, about a foot high; leaves oblong-lanceolate, acute; peduncles terminal, axillary, one or two-flowered; flowers beardless, white without, purplish intermixed with yellow within. A native of Austria.

P. myrtifolia is best propagated by seeds; *P. chamæbuxus*, by dividing its creeping roots.

POLYGAMA. (*πολυς* and *γάμος*, several marriages.) Polygamous plants. In botany. A polygamous plant is that which has hermaphrodite, and either male or female flowers, or both.

POLYGAMIA. In botany, the name of the twenty-third class in the Linnéan system; comprehending those plants which bear hermaphrodite flowers, accompanied with male or female flowers, or both; not inclosed within the same common calyx, but scattered either on the same plant, or on two, or on three distinct individuals. Whence the three orders of this class. 1. Monœcia. 2. Diœcia. 3. Tricœcia.

Some modern reformers have entirely discarded this class, and thus have simplified the Linnéan arrangement, and rendered it more easy to beginners; but they have at the same time wholly mutilated it, considered as a sexual system. - We may go on reforming till we reduce it to the simplicity of Rivinus's system; when it will acquire great facility, and at the same time become good for nothing.

This term *polygamia* or *polygamy*, as applied to a compound flower, in the orders of the class syngenesia, signifies that several distinct flowers (called florets) are included in one common calyx. These may be all hermaphrodite, as in the first order; or hermaphrodites with female flowers as in the second, third, and fourth.

POLYGAMIST. *s.* (from *polygamy*.) One that holds the lawfulness of more wives than one at a time.

POLYGAMY. *s.* (*polygamie*, Fr. *πολυγαμία*.) A plurality of wives or husbands, in the possession of one man or woman at the same time. Polygamy is so universally esteemed unlawful, and even unnatural, through Europe,

and in all Christian countries, that we have generally reasoned upon this conviction. Both religion and reason appear at first sight at least to condemn it; and with this view of the subject mankind in general rest satisfied: but some bolder geniuses have taken the opposite side of the question; have cast off the prejudices of education, and attempted to show that polygamy is not unlawful, but that it is just and necessary, and would be a public benefit.

One of the most specious writers on this side of the question was Mr. Madan, in his *Thelyphthora*. We shall neither detail his reasonings, nor enter into a laboured refutation of such notions; but simply quote the concluding remarks of the Monthly Reviewer of Madan's work. "In a word," says he, "when we reflect that the primitive institution of marriage limited it to one man and one woman; that this institution was adhered to by Noah and his sons, amidst the degeneracy of the age in which they lived, and in spite of the examples of polygamy which the accursed race of Cain had introduced; when we consider how very few (comparatively speaking) the examples of this practice were among the faithful; how much it brought its own punishment with it; and how dubious and equivocal those passages are in which it appears to have the sanction of divine approbation; when to these reflections we add another, respecting the limited views and temporary nature of the more ancient dispensations and institutions of religion—how often the imperfections and even vices of the patriarchs and people of God in old time are recorded, without any express notification of their criminality—how much is said to be commanded, which our reverence for the holiness of God and his law will only suffer us to suppose were, for wise ends, permitted—how frequently the messengers of God adapted themselves to the genius of the people to whom they were sent, and the circumstances of the times in which they lived:—above all, when we consider the purity, equity, and benevolence of the Christian law; the explicit declarations of our Lord, and his apostle St. Paul, respecting the institution of marriage, its design and limitation;—when we reflect, too, on the testimony of the most ancient fathers, who could not possibly be ignorant of the general and common practice of the apostolic church; and, finally, when to these considerations we add those which are founded on justice to the female sex, and all the regulations of domestic economy and national policy—we must wholly condemn the revival of polygamy; and thus bear our honest testimony against the leading design of this dangerous and ill-advised publication."

We would advise our readers to read the whole criticism on Madan's book in the Monthly Review, together with their account of the several answers to it. The reverend author of the *Thelyphthora* has here met with a most able antagonist, who traces him through all his deceitful windings, and exposes the futi-

lity and falsehood of his arguments with singular ability. See Monthly Review, vol. lxiii. p. 273, &c.; see also Paley's *Moral Philosophy*.

It has been disputed by the lawyers, whether polygamy be adultery. In the Roman law it is called *stuprum*, and punished as such, that is, in some cases, capitally. But a smaller punishment is more consistent with the Jewish law, wherein the prohibition of adultery is perpetual, but that of polygamy temporary only.

In Germany, Holland, and Spain, this offence is differently punished. By a constitution of Charles V. it was a capital crime. By the laws of ancient and modern Sweden it is punished with death. In Scotland it is punished as perjury.

In England it is enacted by statute 1 Jac. I. cap. 11: that if any person, being married, do afterwards marry again, the former husband or wife being alive, it is felony, but within the benefit of clergy. The first wife in this case shall not be admitted as an evidence against her husband, because she is the true wife; but the second may, for she is indeed no wife at all; and so *vice versa* of a second husband. This act makes an exception to five cases, in which such second marriage, though in the three first it is void, is, however, no felony. 1. Where either party hath been continually abroad for seven years, whether the party in England had notice of the other's being living or not. 2. Where either of the parties hath been absent from the other seven years within this kingdom, and the remaining party hath had no notice of the other's being alive within that time. 3. Where there is a divorce or separation *a mensa et thoro* by sentence in the ecclesiastical court. 4. Where the first marriage is declared absolutely void by any such sentence, and the parties loosed *a vinculo*. Or, 5. Where either of the parties was under the age of consent at the time of the first marriage; for in such case the first marriage was voidable by the disagreement of either party, which this second marriage very clearly amounts to. But if at the age of consent the parties had agreed to the marriage, which completes the contract, and is indeed the real marriage, and afterwards one of them should marry again, judge Blackstone apprehends that such second marriage would be within the reason and penalties of the act.

POLYGARS, are natives of Hindustan. They inhabit almost impenetrable woods, and are under the absolute direction of their own chieftains. In time of peace they are professionally robbers, but in times of war are the guardians of the country. The general name of these people is Polygar. Their original institution, for they live in distinct clans, is not very well understood. It probably took its rise from the municipal regulations relative to the destruction of tygers and other ferocious beasts. Certain tracts of woodland were indisputably allotted as rewards to those who

should slay a certain number of those animals; and those lands approximating, probably laid the foundation of the several confederacies of Polygars.

POLYGLOTT, Πολυγλωττος, thus called from πολυ, and γλωττα, tongue, language, among divines and critics, chiefly denotes a Bible printed in several languages.

This interesting subject cannot be treated with the fulness it merits, without drawing us beyond our assigned limits. We therefore beg leave to refer the critical reader to the valuable accounts in Dr. Adam Clarke's Bibliographical Dictionary, and in Dibdin's Introduction to the Classics.

POLYGNOTUS, a celebrated painter of Thasos, about 422 years before the Christian era. He adorned one of the public porticoes of Athens with his paintings, and particularly excelled in giving liveliness and expression to his pieces.

POLYGON, Πολυγωνος, formed from πολυς many, and γωνια, angle, in geometry, a multilateral figure, or a figure whose perimeter consists of more than four sides and angles. If the angles be all equal among themselves, the polygon is said to be a regular one; otherwise, it is irregular. Polygons also take particular names according to the number of their sides; thus a Polygon of

3 sides is called a trigon,

4 sides is called a tetragon,

5 sides is called a pentagon,

6 sides is called a hexagon, &c.

and a circle may be considered as a polygon of an infinite number of small sides, or as the limit of the polygons.

Polygons have various properties, as below:

1. Every polygon may be divided into as many triangles as it hath sides.

2. The angles of any polygon taken together, make twice as many right angles, wanting 4, as the figure hath sides. Thus, if the polygon has 5 sides; the double of that is 10, from which subtracting 4, leaves 6 right angles, or 540 degrees, which is the sum of the 5 angles of the pentagon. And this property, as well as the former, belongs to both regular and irregular polygons.

3. Every regular polygon may be either inscribed in a circle, or described about it. But not so of the irregular ones, except the triangle, and another particular case as in the following property.

An equilateral figure inscribed in a circle is always equiangular.—But an equiangular figure inscribed in a circle is not always equilateral, but only when the number of sides is odd. For if the sides be of an even number, then they may either be all equal, or else half of them may be equal, and the other half equal to each other, but different from the former half, the equals being placed alternately.

4. Every polygon, circumscribed about a circle, is equal to a right-angled triangle, of which one leg is the radius of the circle, and the other the perimeter or sum of all the sides

of the polygon. Or the polygon is equal to half the rectangle under its perimeter and the radius of its inscribed circle, or the perpendicular from its centre upon one side of the polygon.

Hence, the area of a circle being less than that of its circumscribing polygon, and greater than that of its inscribed polygon, the circle is the limit of the inscribed and circumscribed polygons: in like manner the circumference of the circle is the limit between the perimeters of the said polygons: consequently the circle is equal to a right-angled triangle, having one leg equal to the radius, and the other leg equal to the circumference; and therefore its area is found by multiplying half the circumference by half the diameter. In like manner, the area of any polygon is found by multiplying half its perimeter by the perpendicular admitted from the centre upon one side.

5. The following table exhibits the most remarkable particulars in all the polygons, up to the dodecagon of 12 sides, viz. the angle at the centre, the angle of the polygon, and the area of the polygon when each side is 1. See fig. 7. pl. 139.

No. of sides.	Name of polygon.	Ang. F. at cent.	Ang. C. of polyg.	Area
3	Trigon	120°	60°	0.4330127
4	Tetragon	90	90	1.0000000
5	Pentagon	72	108	1.7204774
6	Hexagon	60	120	2.5980762
7	Heptagon	51 $\frac{3}{4}$	128 $\frac{1}{2}$	3.6539124
8	Octagon	45	135	4.8284271
9	Nonagon	40	140	6.1818242
10	Decagon	36	144	7.6942088
11	Undecagon	32 $\frac{2}{11}$	147 $\frac{3}{11}$	9.3656399
12	Dodecagon	30	150	11.1961524

Problem concerning polygons. 1. On a regular polygon to circumscribe a circle, or to circumscribe a regular polygon upon a circle. Bisect two of the angles of the given polygon A and B by the right lines AF, BF; and on the point F, where they meet, with the radius AF, describe a circle which will circumscribe the polygon. Next to circumscribe a polygon, divide 360 by the number of sides required, to find $e F d$; which set off from the centre F, and draw the line de , on which construct the polygon as in the following problem. 2. On a given line to describe any given regular polygon. Find the angle of the polygon in the table, and in E set off an angle equal thereto; then drawing $EA = ED$, through the points E, A, D, describe a circle, and in this applying the given right line as often as you can, the polygon will be described. 3. To find the sum of all the angles in any given regular polygon. Multiply the number of sides by 180° ; from the product subtract 360° , and the remainder is the sum required: thus, in a pentagon, $180 \times 5 = 900$, and $900 - 360 = 540 =$ the sum of all the angles in a pentagon.

To find the area of any regular polygon.—Multiply the square of its side by the tabular area, found on the line of its name in the last column of the table, and the product will be the area. Thus, to find the area of the trigon, or equilateral triangle, whose side is 20. The square of 20 being 400, multiply the tabular area .4330127 by 400, as in the margin, and the product 173.2050800 will be the area.

$$\begin{array}{r} 0.4330127 \\ \times 400 \\ \hline 173.2050800 \end{array}$$

There are several curious algebraical theorems for inscribing polygons in circles, or finding the chord of any proposed part of the circumference, which is the same as angular sections. These kinds of sections, or parts and multiplies of arcs, were first treated of by Vieta, as shewn in the Introduction to Hutton's Log. pa. 9. and since pursued by several other mathematicians, in whose works they are usually to be found.

POLYGON, in fortification, denotes the figure or perimeter of a fortress, or fortified place. This is either exterior or interior.

Exterior polygon, is the perimeter or figure formed by lines connecting the points of the bastions to one another, quite round the work. And

Interior polygon, is the perimeter or figure formed by lines connecting the centres of the bastions, quite around.

POLYGONS (Line of), is a line on some sectors, containing the homologous sides of the first nine regular polygons inscribed in the same circle; viz, from an equilateral triangle to a dodecagon.

POLYGONAL NUMBERS, are the continual or successive sums of a rank of any arithmeticals beginning at 1, and regularly increasing; and therefore are the first order of figurate numbers: they are called Polygons, because the number of points in them may be arranged in the form of the several polygonal figures in geometry, as is illustrated under the article FIGURATE NUMBERS, which see.

The several sorts of polygonal numbers, viz. the triangles, squares, pentagons, hexagons, &c. are formed from the addition of the terms of the arithmetical series, having respectively their common difference 1, 2, 3, 4, &c.; viz. if the common difference of the arithmeticals be 1, the sums of their terms will form the triangles; if 2, the squares; if 3, the pentagons; if 4, the hexagons, &c. Thus:

- { Arith. progres. 1, 2, 3, 4, 5, 6, 7.
- { Triang. nos. 1, 3, 6, 10, 15, 21, 28.
- { Arith. progres. 1, 3, 5, 7, 9, 11, 13.
- { Square nos. 1, 4, 9, 16, 25, 36, 49.
- { Arith. progres. 1, 4, 7, 10, 13, 16, 19.
- { Pentag. nos. 1, 5, 12, 22, 35, 51, 70.
- { Arith. progres. 1, 5, 9, 13, 17, 21, 25.
- { Hexag. nos. 1, 6, 15, 28, 45, 66, 91.

The side of a polygonal number is the number of points in each side of the polygonal

figure when the points in the number are ranged in that form. And this is also the same as the number of terms of the arithmeticals that are added together in composing the polygonal number; or, in short, it is the number of the term from the beginning. So, in the 2d or squares,

the side of the first (1) is 1, that of the second (4) is 2, that of the third (9) is 3, that of the fourth (16) is 4, and so on. And

The angles, or numbers of angles, are the same as those of the figure from which the number takes its name. So the angles of the triangular numbers are 3, of the square ones 4, of the pentagonals 5, of the hexagonals 6, and so on. Hence, the angles are 2 more than the common difference of the arithmetical series from which any rank of polygons is formed: so the arithmetical series has for its common difference the number 1 or 2 or 3, &c. as follows, viz. 1 in the triangles, 2 in the squares, 3 in the pentagons, &c.; and, in general, if a be the number of angles in the polygon, then $a-2$ is d the common difference of the arithmetical series, or $d+2=a$ the number of angles.

PROB. 1.—To find any polygonal number proposed; having given its side n and angles a . The polygonal number being evidently the sum of the arithmetical progression whose number of terms is n and common difference $a-2$, and the sum of an arithmetical progression being equal to half the product of the extremes by the number of terms, the extremes being 1 and $1+d$. $(n-1) = 1 + (a-2) \cdot (n-1)$; therefore that number, or this sum, will be $\frac{n^2 d - n \cdot (d-2)}{2} = \frac{n^2 (a-2) - n \cdot (a-4)}{2}$, where

d is the common difference of the arithmeticals that form the polygonal number, and is always 2 less than the number of angles a .

Hence, for the several sorts of polygons, any particular number whose side is n , will be found from either of these two formulæ, by using for d its values 1, 2, 3, 4, &c.; which gives these following formulæ for the polygonal number in each sort, viz. the

$$\begin{aligned} \text{Triangular} &= \frac{n^2 + n}{2}, \\ \text{Square} &= \frac{2n^2 - 0n}{2} = n^2, \\ \text{Pentagonal} &= \frac{3n^2 - n}{2}, \\ \text{Hexagonal} &= \frac{4n^2 - 2n}{2}, \end{aligned}$$

$$\text{Heptagonal} - \frac{5n^2 - 3n}{2},$$

&c.

PROB. 2.—To find the sum of any number of polygonal numbers of any order.—Let the angles of the polygon be a , or the common difference of the arithmeticals that form the polygonals, d ; and n the number of terms in the polygonal series, whose sum is sought; then is

$$\left(\frac{n^2-1}{6}d + \frac{n+1}{2}\right)n \text{ or } \left(\frac{n^2-1}{6} \cdot a - 2 + \frac{n+1}{2}\right)n$$

the sum of the n terms sought.

Hence, substituting successively the numbers 1, 2, 3, 4, &c. for d , there is obtained the following particular cases, or formulæ, for the sums of n terms of the several ranks of polygonal numbers, viz. the sum of the

$$\text{Triangulars} - \frac{n^2 + 3n + 2}{6} n,$$

$$\text{Squares} - \frac{2n^2 + 3n + 1}{6} n,$$

$$\text{Pentagonals} - \frac{3n^2 + 3n + 0}{6} n,$$

$$\text{Hexagonals} - \frac{4n^2 + 3n - 1}{6} n,$$

$$\text{Heptagonals} - \frac{5n^2 + 3n - 2}{6} n,$$

(Hutton's Math. Dict.)

POLYGONOMETRY, the measure or doctrine of polygons. For a brief treatise on this subject, see the 3d vol. of Dr. Hutton's Course of Mathematics.

POLYGONOUS STEM, in botany, a many-angled stem. Having several (more than six) prominent longitudinal angles. Delin. Pl. But in Philos. Bot. it is a species of aneups. Multangular is explained in Delin. Pl. to be excavated longitudinally by several hollow angles. According to this explanation, therefore, the former term refers to the angles in cameo, the second to those in intaglio. But in Philos. Bot. the multangular stem is said to have several prominent angles.

POLYGONUM, in botany, a genus of the class octandria, order trigynia. Calyx five-parted, coloured, resembling a corol, permanent; corollæ; seed one, superior, angular, covered with the calyx; stamens and pistils irregular in number. Forty-two species, scattered over Europe, Asia, and America, of which ten are common to our own country. They may be thus subdivided into sections.

A. Stem shrubby; forming the atraphaxoides of many writers.

B. With a single spike; embracing the family of bistorts.

C. With bifid pistil, or stamens fewer than eight: the family of persicarias.

D. With undivided leaves and eight stamens. Proper polygonums.

E. With leaves somewhat heart-shaped: the tribe of helxine.

The following are chiefly entitled to notice.

1. *P. bistorta*. Bistort. Found wild in our pastures, and employed as a styptic in medicine. See **BISTORTA**.

2. *P. orientale*. Arsmath. Oriental persicary. Root tufted, fibrous; stem erect, jointed, hairy, eight or ten feet high; leaves alternate, ovate, often a foot long, and six inches broad in the middle; flowers in long, terminating spikes, pendulous; stamens five, six or seven. A native of India, flowering from July to October: easily raised from seeds; and supposed to arise from scattered seeds more readily than from those that are sown. This is the only cultivated species of the whole genus; but it has a dwarf variety that is also cultivated.

3. *P. aviculare*. Knot-grass. Found in the wastes of our own country, with leaves short, long, oblong, or linear, procumbent, herbaceous stem. It is used in some countries medicinally under the name of **CENTURNODIA**, which see.

4. *P. fagopyrum*. Buck-wheat. Brank. Found in our cultivated fields; rises with an upright, smooth, branchy stem, from about a foot to half a yard high; leaves heart-arrow-shaped; branches terminated by clusters of whitish flowers; seeds with even angles: an excellent food for pigeons and other poultry.

POLYGRAM. *s.* (πολυς αἰά γραμμα.) A figure consisting of a great number of lines.

POLYGRAPHY. *s.* (πολυς and γραφν.) The art of writing in several unusual manners of ciphers; as also deciphering the same.

POLYGYNY. (πολυς, and γυν, a wife.) The name of one of the orders in the fifth, sixth, twelfth, and thirteenth classes of the Linnæan system; comprehending those plants which have flowers with many pistils.

POLYHEDRON, or **POLYEDRON**, a body or solid contained by many rectilinear planes or sides.

When the sides of the polyhedron are regular polygons, all similar and equal, then the polyhedron becomes a regular body, and may be inscribed in a sphere; that is, a sphere may be described about it, so that its surface shall touch all the angles or corners of the solid. There are but five of these regular bodies, viz. the tetraedron, the hexaedron or cube, the octaedron, the dodecaedron, and the icosaedron. See **REGULAR BODY**, and each of those five bodies severally.

POLYHEDRON (Gnomonical), is a stone with several faces, on which are projected various kinds of dials. Of this sort, that in the Privy-garden, London, now gone to ruin, was esteemed the finest in the world.

POLYHYMNIA and **POLYMNIA**, one of the Muses, daughter of Jupiter and Mnemosyne. She presided over singing and rhetoric, and was deemed the inventress of harmony.

POLYLOGY. *s.* (πολυς and λογος.) Talkativeness.

POLYMATHY. *s.* (πολυς and μαθανω.)

The knowledge of many arts and sciences; also an acquaintance with many different subjects.

POLYMEDE, a daughter of Autolycus, who married *Æson*, by whom she had Jason. She survived her husband only a few days.

POLYMELA, one of Diana's companions, daughter of Phylas. She had a son by Mercury.

POLYMNESTOR, a king of the Thracian Chersonesus, who married *Hione*, the eldest of Priam's daughters. When the Greeks besieged Troy, Priam sent the greatest part of his treasures, together with Polydorus, the youngest of his sons, to Thrace, entrusted to the care of Polymnestor, who, when informed that Priam was dead, murdered his brother-in-law to become master of the treasures. At that time the Greeks were returning victorious from Troy, followed by all the captives, among whom was Hecuba, the mother of Polydorus. The fleet stopped on the coasts of Thrace, where one of the female captives discovered on the shore the body of Polydorus, whom Polymnestor had thrown into the sea. Hecuba and her captive associates, for this act of cruelty and perfidy, put out the eyes of the tyrant, and murdered his two children. (*Euripid. Virg. Ovid, &c.*) Hyginus relates the story in a different manner.

POLYMNIA, in botany, a genus of the class syngenesia, order polygamia necessaria. Receptacle chaffy; downless; calyx double, the outer four or five-leaved; inner ten-leaved, leaves concave. Three species; natives of America or Abyssinia.

POLY (Mountain). See **TEUCRIUM**.

POLYNEMUS. Polyneme. In zoology, a genus of the class pisces, order abdominalia. Head compressed, covered with scales; snout very obtuse and prominent; gill-membrane from five to seven-rayed; pectoral fins with distinct appendages. Four species; three inhabitants of America, one of the Pacific Ocean. They are chiefly distinguished from the genus *trigla*, in having the ventral fins placed on the abdomen, and in the appendages not being articulate. Their bodies are oblong, thick, and covered with scales; as is also the head, which slopes off into an obtuse snout. The jaws are of equal length when open; but when shut, the lower is longest; both are furnished with small, thick, and immoveable teeth. The tongue is narrow and smooth; but the palate is armed with a number of sharp tubercles. The eyes are of a middle size, placed at a great distance from each other, and covered with the common tegument of the head; before them appear the two large apertures of the nose.

The sides are compressed, and the abdomen carinated; each of the lateral lines are smooth, and bend in a direction parallel to the back. There are two dorsal fins; the first spinous, and placed about the fish's equilibrium; the second, which is larger, behind it. The pectoral fins are long and narrow; the ventral are

placed in the abdomen; the tail is large, broad, and bifurcated.

We shall offer a specimen or two:

1. *P. paradiseus*. Mango-fish. Appendages seven; tail forked. The colour is yellowish, resembling that of a ripe mango; whence its specific name. It is an inhabitant of the Indian and American seas; about twelve or fifteen inches long. At Calcutta its flesh is accounted delicate.

2. *P. plebeius*. Grey polyneme. Appendages five, the first extending beyond the tail, the others gradually shortening. Inhabits the Pacific Ocean, and has the general appearance of a mullet, but with the head very obtuse in front, the mouth seeming to be placed beneath. Each of these species appears to have varieties, which some writers have made distinct species.

Mr. Bruce, in the appendix to his travels, gives a drawing and an account of a fish, which he conceives should belong to this genus, and which is hence denominated *P. niloticus*. We have some doubts, however, whether this fish is properly arranged. The specimen this traveller saw taken in the Nile weighed thirty-two pounds; and he adds, that it often reaches the weight of seventy pounds, and inhabits the Nile as high up as Syene and the first cataract. The whole body is covered with scales of a brilliant silver colour, so as to resemble an assemblage of spangles; the nose has a shade of red at the end, which is the only variety of colour the fish exhibits.

POLYNICES, a son of *Cedipus*, king of Thebes, by *Jocasta*. He inherited his father's throne with his brother *Eteocles*, and it was mutually agreed between them, that they should reign each a year alternately. *Eteocles* first ascended the throne, but, when the year was expired, he refused to resign the crown to his brother. *Polynices*, upon this, fled to Argos, where he married *Argia*, the daughter of *Adrastus*, the king of the country, and levied a large army, at the head of which he marched against Thebes. The command of this army was divided among seven celebrated chiefs, who were to attack the seven gates of the city of Thebes. The battle was decided by a single combat between the two brothers, who each killed the other.

POLYPE, in helminthology. See **HYDRA**.

POLYPETALOUS COROL. In botany. A polypetalous corolla; or, a corol of many petals. Linnéus uses this term in opposition to a monopetalous corol; that is, consisting of one petal only. By former writers it was commonly put for a flower of more than six petals; and Linnéus uses the terms *monopetala*, *dipetala*, &c.

POLYPHEMUS, in fabulous history, king of all the Cyclops in Sicily, and son of *Nephtune* and *Thoosa*. He is represented as a monster of immense strength, and with one eye in the middle of the forehead. He fed upon human flesh, and kept his flocks on the

coasts of Sicily, when Ulysses, at his return from the Trojan war, was driven there. The Grecian prince, with twelve of his companions, visited the coast, and were seized by the Cyclops, who daily devoured two of them in his cave, in which they were confined. Ulysses would have shared the same fate had he not intoxicated the Cyclops, and put out his eye with a firebrand while asleep. Polyphemus, awaked by the sudden pain, stopped the entrance of his cave, but Ulysses made his escape by creeping between the legs of the rams of the Cyclops, which had been put up in the cave. Polyphemus became enamoured of Galatæa, but his addresses were disregarded, and the nymph shunned his presence. The Cyclops, when he saw Galatæa surrender herself to the pleasures of Acis, crushed his rival with a piece of a broken rock.

POLYPHONISM. *s.* (πολύς and φωνή.) Multiplicity of sound (*Derham*).

POLYPHYLLOUS, in botany, many-leaved. Applied to the calyx, perianth, involucre, and cirrus or tendril; in opposition to monophyllous, one-leaved. Here also Linnæus uses diphyllus, triphyllus, &c.

POLYPODIUM. Polypody. In botany, a genus of the class cryptogamia, order filices. Fructification in roundish, scattered dots, not marginal; involucreless. Seventy-six species, five indigenous. They may be thus subdivided into sections.

- A. Frond simple.
- B. Frond pinnatifid.
- C. Frond pinnate.
- D. Frond doubly pinnatifid or doubly pinnate.
- E. Frond more than decomposed.

The following are chiefly entitled to notice.

1. *P. vulgare*. Common polypody. Segments linear, oblong, obtuse, slightly serrate; not scaly. The leaves have a weak ungrateful smell, and a nauseous sweet taste, leaving a kind of roughness and slight acrimony in the mouth. They give out their smell and taste, together with a yellow colour, both to water and rectified spirit. The spirituous tincture is sweeter than the watery; but in inspissation its sweetness is in great part destroyed, or covered by the other matter; the spirituous extract, as Cartheuser observes, being to the taste only subadstringent and subacid, with very little sweetness, while the watery extract retains the full sweetness of the polypody. A native of our own country.

2. *P. quercanum*. Oak polypody. Futile; fronds pinnatifid, with lanceolate segments; barren ones sessile, ovate, sinuate. The root of this fern grows on the oak, whence its specific name; it was employed by the ancients as a purgative, and thought to be peculiarly useful in expelling bile and pituitous humours, therefore much used in maniacal and melancholic disorders; but, to act as a cathartic, the root must be exhibited in its recent state, and in a large dose. Another character in which it has been recommended, and for

which, from its sensible qualities, it seems to promise more advantage, is that of a demulcent or pectoral; thus, joined with liquorice, its good effects have been experienced in coughs and asthmatic affections. However, it is now rarely used in this country, nor have the French authors, Poissoner and Malouin, who have cited instances of its success in mania, been able to restore to it its ancient reputation in this calamitous disorder.

3. *P. filix mas*. Male polypody. Divisions pinnate; subdivisions oblong, obtuse, serrate at top; stalk scaly. Indigenous to our own country. It is often burnt for the sake of its alkaline ashes, which are bought by the soap-makers and glass manufacturers. The Norwegians are said to boil and eat it as asparagus, and to give it in the same state to their cattle as fodder. In medicine it has been long employed as a vermifuge under its specific name of *FILIX MAS*, which see.

POLYPOUS. *a.* (from *polypus*.) Having the nature of a polypus; having many feet or roots (*Arbutnot*).

POLYPREMIUM, in botany, a genus of the tetandria monogynia class and order. Natural order of Caryophyllei. Scrophulariæ, Jussieu. Essential character: calyx four-leaved; corolla four-cleft; wheel-shaped, with obcordate lobes; capsule compressed, emarginate, two-celled. There is but one species, viz. *P. procumbens*, a native of Carolina and Virginia.

POLYPUS. (πολύπους; from πολύς, many, and πούς, a foot, from its sending off many ramifications like legs.) This term is generally given to a sarcomatous substance that frequently arises in the nostrils, uterus, &c. from its having many attachments or roots. They vary from each other according to the different causes that produce them, and the alterations that happen in them. Sometimes a polypus is owing to a swelling of the pituitary membrane, which swelling may possess a greater or less space of the membrane, as also its cellular substance, and may affect either one or both nostrils. At other times it arises from an ulcer produced by a caries of some of the bones which form the internal surface of the nostrils. Polypuses are sometimes so soft, that upon the least touch they are lacerated, and bleed; at other times they are very compact, and even scirrhous. Some continue small a great while; others increase so fast as in a short time to push out at the nostrils, or extend backward towards the throat. Le Dran mentions, that he has known them fill up the space behind the uvula, and turning towards the mouth, have protruded the fleshy arch of the palate so far forwards as to make it parallel with the third dentes molares. There are others, which, though at first free from any malignant disposition, become afterwards carcinomatous, and even highly cancerous. Of whatever nature the polypus is, it intercepts the passage of the air through the nostril, and, when large, forces the septum narium into the other nostril,

so that the patient is unable to breathe, unless through the mouth. A large polypus pressing in like manner upon the spongy bones, gradually forces them down upon the maxillary bones, and thus compresses and stops up the orifice of the ductus lachrymalis; nor is it impossible for the sides of the canalis nasalis to be pressed together. In which case, the tears having no passage through the nose, the eye is kept constantly watering, and the sacculus lachrymalis not being able to discharge its contents, is sometimes so much dilated, as to form what is called a flat fistula.

The coagulable substance which is found in the cavities of the heart of those who are some time in *articulo mortis*, is improperly called a polypus.

POLYPUS, in zoology. See **HYDRA**.

POLYSARCIA. (*πολυσαρκία*, from *πυλός*, much, and *σάρξ*, flesh.) Troublesome corpulency or fatness. A genus of disease in the class cachexiæ and order intumescentiæ of Cullen.

POLYSCOPE, or **POLYHEDRON**, in optics, is a multiplying glass, being a glass or lens which represents a single object to the eye as if it were many. It consists of several plane surfaces, disposed into a convex form, through every one of which the object is seen.

POLYSPAST: *s.* (*polyspaste*, French.) A machine consisting of many pulleys.

POLYSPERMOUS CAPSULE or **BERRY**. A many-seeded capsule or berry, containing several seeds.

POLYSTACHYOUS CULM. A culm bearing several spikes. As in *scirpus lacustris*, *holoschœnus*, and *setaceus*.

POLYSTRATUS, a Macedonian soldier, who found Darius after he had been stabbed by Besus, and who gave him water to drink, and carried the last injunctions of the dying monarch to Alexander.

POLYSYLLABICAL. *a.* (from *polysyllable*.) Having many syllables; pertaining to a polysyllable.

POLYSYLLABLE. *s.* (*πολυς* and *συλλαβή*.) A word of many syllables (*Holder*).

POLYSYNDETON. *s.* (*πολυσυνδeton*.) A figure of rhetoric by which the copulative is often repeated: as, I came, and saw, and overcame.

POLYTRICHUM. Golden maidenhair. In botany, a genus of the class cryptogamia, order musci. Capsule oblong or quadrangular; fringe simple, of thirty-two or sixty-four short incurved teeth, connected at top by a flat membrane; veil hairy, often double. Twenty-six species, half indigenous. They may be thus subdivided:

A. Stemless or nearly so.

B. Stem simple.

C. More or less branched.

Of these *P. commune* is the only one we can notice: it is frequently found in our bogs with linear-lanceolate, acute, serrulate, spread leaves; capsule square, on a roundish receptacle. It grows in patches, and its stalks run

VOL. IX.

from three inches to a foot or even a yard high. In England it is sometimes employed to make brooms or brushes, and in Lapland to make their beds. The mode in which this bed is manufactured is curious. They cut an entire patch of turf large enough for this purpose, with the fern still growing upon it; this constitutes the bed, and the covering or counterpane is formed by another patch of turf equally covered with this fern, and this they throw over themselves by inverting it, so that they sleep soundly in the middle of the two layers of the fern.

POLYTHEISM. (from *πολυ*, much, and *θεος*, *deus*.) The doctrine or belief of a plurality of gods. See **GOD**, **IDOLATRY**, **JUPITER**, &c.

POLYTHEIST. *s.* (*πολυς* and *θεος*.) One that holds plurality of gods (*Duncomb*).

POLYXENA, a daughter of Priam and Hecuba, celebrated for her beauty. Achilles became enamoured of her, and their marriage would have been consummated, had not Hector, her brother, opposed it. Polyxena, it is said, accompanied her father when he went to the tent of Achilles to redeem the body of Hector. Some time after, Achilles came into the temple of Apollo to obtain a sight of the Trojan princess, but he was murdered there by Paris; and Polyxena was so afflicted at his death, that she sacrificed herself on his tomb. Some say that the princess, who was in the number of the captives, was dragged to her lover's tomb, and there immolated by Neoptolemus, the son of Achilles.

POLYXO, a native of Argos, who married Tlepolemus, son of Hercules. She followed him to Rhodes after the murder of his uncle Lycymnius, and when he departed for the Trojan war with the rest of the Greek princes, she became the sole mistress of the kingdom. After the Trojan war Helen fled from Peloponnesus to Rhodes, where Polyxo reigned. Polyxo detained her, and to punish her, as being the cause of a war in which Tlepolemus had perished, she ordered her to be hanged on a tree by her female servants, disguised in the habit of Furies. See **HELENA**.

POMACEÆ, in botany, the name of the thirty-seventh order in Linnæus's fragments, and of the thirty-sixth in his natural orders. Comprehending such plants as bear a pome, or fruit resembling the apple.

POMACEOUS. *a.* (from *pomum*, Latin.) Consisting of apples (*Philips*).

POMADE. *s.* (*pomade*, Fr. *pomado*, Ital.) A fragrant ointment.

POMANDER. *s.* (*pomme d'ambre*, Fr.) A sweet ball; a perfumed ball or powder (*Shakspeare*).

POMATUM. *s.* (Latin.) An ointment, scented to rub on the head.

To POME. *v. n.* (*pommer*, Fr.) To grow to a round head like an apple.

POME. (*pomum*.) In botany. Pericarpium factum e valve, capsulam continens. A pulpy pericarp, without valves, containing a

M M

capsule. It includes all the moist fruits which have the seeds lodged in a core; as, apple, pear, quince, &c.

POMEGRANATE. See **GRANATUM** and **PUNICA**.

POMERANIA, a duchy of Germany, in the circle of Upper Saxony; bounded on the N. by the Baltic, on the E. by Western Prussia and Poland, on the S. by Brandenburg, and on the W. by Mecklenburg. It is watered by several rivers, of which the Oder, Recknitz, Pene, Ucker, Rega, Persanet, Wipper, Ihna, Stolpen, and Lebo, are the most considerable. The air is pretty cold, but compensated by the fertility of the soil, which abounds in pastures and corn, of which a great deal is exported. It is a flat country, containing many lakes, woods, and forests, and has several good harbours, particularly Stetin and Stralsund. It is 250 miles long and 75 broad, and divided into Hither and Further Pomerania. The latter and part of Hither Pomerania belong to the king of Prussia; the remainder to the king of Sweden. Stetin is the capital of the Prussian part, and Stralsund of the Swedish.

POMERELIA, a district of Polish or Western Prussia, forcibly seized by the king of Prussia. Danzig is the capital.

POMESANIA, a large county of Western Prussia, which extends from E. to W. from the Passarge as far as the Vistula, between E. and W. Prussia. It is full of lakes and morasses.

POMETIA, in botany, a genus of the class monœcia, order hexandria. Calyx one-leaved, six-cleft; petals six. Male: filaments six, on the margin of the nectary. Female: berry globular, with a single seed in the centre. Two species; natives of New South Wales.

POMEY (Francis), a jesuit of Lyons, known by his *Panthœum Mysticum*, translated into English by Andrew Tooke, as his own performance. He wrote besides a French and Latin Dictionary, 4to.—*Flos Latinitatis*—*Libitina*, on the Funerals of the Ancients—*Novus Rhetoricæ Candidatus*; and died, 1673, aged 55.

POMFRET (John), an English poet, born about 1667, at Luton, Bedfordshire. He was educated at Cambridge, and obtained the living of Maldon, in Bedfordshire. In 1703 he came to London for a larger living, but found bishop Compton strongly prejudiced against him, for four lines in his poem called *Choice*, in which it was falsely said, that he preferred a mistress to a wife, and before the prelate's scruples could be removed, the unfortunate candidate caught the small-pox, and died of it, aged 35. In his *Cruelty and Lust*, he has introduced the character of Kirk with great effect and pathos. No poem, says Johnson, has been oftener perused than his *Choice*. He pleases many, and he who pleases must have merit.

POMIFEROUS. *a.* (*pomifer*, Latin.) A

term applied to plants which have the largest fruit, and are covered with a thick hard rind.

PO'MMEL. *s.* (*pomeau*, Fr.) 1. A round ball or knob (*Sidney*). 2. The knob that balances the blade of the sword (*Sidney*). 3. The protuberant part of a saddle before.

To Po'MMEL. *v. a.* (*pommeler*, Fr. *to va-riegate*.) To beat with any thing thick or bulky; to beat black and blue; to bruise; to punch.

POMMEREULLIA, in botany, a genus of the class triandria, order monogynia. Calyx turbinate, two-valved, three or four flowered; valves four-cleft, awned at the back; corol two-valved, awned. One species; a small Indian grass, with flowers like the shuttlecock.

POMONA, a nymph at Rome who was supposed to preside over gardens, and to be the goddess of all sorts of fruit-trees. She had a temple at Rome, and a regular priest called *Flamen Pomonalis*, who offered sacrifices to her divinity for the preservation of fruit. She was generally represented as sitting on a basket full of flowers and fruit, and holding a bough in one hand, and apples in the other. Many of the gods of the country endeavoured to gain her affection, but Vertumnus was the only one who prevailed upon her to marry him. This deity was unknown among the Greeks.

POMONA, the principal of the Orkney Islands. See **MAINLAND**.

POMP. *s.* (*pompa*, Latin.) 1. Splendour; pride (*Shakspeare*). 2. A procession of splendour and ostentation (*Addison*).

POMPADOUR (Jane Antoinette Poisson, marchioness of), the mistress of Louis XV. was daughter of a financier, and married D'Etiole. The licentious monarch first saw her while he was hunting in the forest of Senar, and from that time he made her his favourite, and raised her, in 1745, to the rank of a marchioness. She enjoyed great influence at court till her death, 1764, at the age of 44. The liberal manner with which she patronized literature has in some degree blunted the shafts of criticism against the infamy of her life. Her memoirs have been published, 2 vols. 8vo. and all her letters, 3 vols.

POMPEIA. The most remarkable of this name was a daughter of Pompey the Great, Julius Cæsar's third wife. She was accused of incontinence, because Clandius had introduced himself in women's clothes into the room where she was celebrating the mysteries of Cybele. Cæsar repudiated her upon this accusation.

POMPEIANUS. The most remarkable of this name is a Roman knight of Antioch, raised to offices of the greatest trust, under the emperor Aurelius, whose daughter, Lucilla, he married. He lived in great popularity at Rome, and retired from the court when Commodus succeeded to the imperial crown.

POMPEII, or **POMPEIUM**, a town of

Campania, partly demolished by an earthquake, A. D. 63, and afterwards rebuilt. Sixteen years after it was swallowed up by another earthquake, which accompanied one of the eruptions of mount Vesuvius. Herculaneum was destroyed at the same time.

POMPEIOPOLIS, a town of Cilicia, formerly called Soli.

POMPEIUS. Pompey. This name was common to many illustrious Romans, the most celebrated of whom is Cneus, surnamed Magnus, from the greatness of his exploits. He was son of Pompeius Strabo, and Lucilia. He early distinguished himself in the field, under his father, whose courage and military prudence he imitated. He began his career with great popularity, and in pleading at the bar he received unbounded applause. In the disturbances of Marius and Sylla, Pompey followed the interest of the latter; and in the 26th year of his age he conquered Sicily, and in forty days he regained that part of Africa which had forsaken the interest of Sylla. This rapid success astonished Sylla, who dreading the rising power of Pompey, recalled him to Rome. Pompey obeyed, and the dictator at his return saluted him with the appellation of *the Great*. Having obtained a triumph, though only a Roman knight, he now appeared not as a dependant, but as a rival of the dictator. After the death of Sylla, Pompey supported himself against the remains of the Marian faction, headed by Lepidus. He defeated them, put an end to the war of Sertorius in Spain, and obtained a second triumph, though still a private citizen, about 73 years before the Christian era. He was soon after made consul, and in that office he prosecuted the piratical war, and extirpated the maritime robbers who had almost destroyed the naval power of Rome in the Mediterranean. He was next appointed to the command of the Mithridatic war, in which, in a general engagement, the Romans so totally defeated the enemy, that Mithridates escaped with difficulty from the field of battle. Having conquered a vast tract of Asia, and, like a master of the world, disposed of kingdoms and provinces, Pompey at length returned to Italy with all the pomp of an eastern conqueror. The Romans dreaded his approach, but he banished their fears by disbanding his army. This modest behaviour gained him more real friends than the most unbounded power. For these signal services he was honoured with a triumph. To strengthen himself in his power, Pompey soon after united his interest with that of Cæsar and Crassus, who formed the first triumvirate. The agreement was completed by the marriage of Pompey with Julia the daughter of Cæsar, and the provinces of the republic were arbitrarily divided among the triumvirs. This confederacy, however, was soon broken by the sudden death of Julia, and the total defeat of Crassus in Syria. Pompey dreaded his father-in-law, and yet he affected to despise him; and by suffering anarchy to prevail in Rome, he convinced his fellow citizens of the necessity of

investing him with dictatorial power. But while the conqueror of Mithridates was a sovereign at Rome, the adherents of Cæsar were not silent. The breach henceforth widened between the two illustrious characters, and Cæsar at length passed the Rubicon, the boundary of his province, which act was, on his side, a declaration of war, and marched immediately to Rome. Pompey did not await his approach, but abandoned that city, and fled to Brundisium, with the consuls, and part of the senators. His cause was popular, and Cato, by embracing it, seemed to indicate, that he was the assertor of Roman independence. But Cæsar was now master of Rome, and in sixty days all Italy acknowledged his power. Having gained the western parts of the Roman empire to espouse his cause, Cæsar crossed Italy and arrived in Greece, where Pompey had retired, supported by all the power of the east, and the wishes of the republican Romans. At length the two hostile armies engaged in the plains of Pharsalia, in Thessaly. The whole was conducted against the advice and approbation of Pompey, and his usual good fortune deserted him. His cavalry soon gave way, and the general seeing a complete defeat ensue, retired to his camp, overwhelmed with grief, where he disguised himself, and fled to the sea coast, whence he passed to Egypt, to seek an asylum in the court of Ptolemy, who had the baseness to betray him. A boat was sent to fetch him on shore, and the Roman general having left his galley, after an affectionate parting with his wife Cornelia, was assassinated by Achilles and Septimius on the shore in the presence of Cornelia. He died B. C. 48, in the 58th or 59th year of his age. His head was cut off, and sent to Cæsar, who turned away from it with horror, and shed a flood of tears. Cæsar erected a monument on his remains. The character of Pompey is that of an intriguing and artful general, and the *oris proli* and *animo invêrecundo* of Sallust; is the most descriptive picture of his character. In his private character, however, he lived with great temperance and moderation. Pompey married four different times. His marriage with Julia, the daughter of Cæsar, was a step more of policy than affection. Yet Julia loved Pompey with great tenderness, and her death in child-bed was the signal of war between her husband and her father. He afterwards married Cornelia, the daughter of Metellus Scipio, a woman commended for her virtues, beauty, and accomplishments.—2. The two sons of Pompey the Great, called Cneius and Sextus, were masters of a powerful army, when the death of their father was known. They prepared to oppose the conqueror, but were defeated by Cæsar at the battle of Munda, and Cneius was left among the slain. Sextus fled to Sicily, where he for some time supported himself; but the murder of Cæsar giving rise to new events, he was at length defeated in a naval engagement by Octavius and Lepidus, and, of all his numerous fleet, consisting of 350, only 17 sail accompanied his flight to Asia.

Here for a moment he raised seditions, but Antony ordered him to be seized and put to death, about 35 years before the Christian era. Sextus vainly styled himself the son of Neptune and Lord of the Seas.

POMPHOLYX. (πομφολυξ, from πομφος, a bladder.) See **TUTIA**.

POMPIGNAN (John James le Franc, marquis of), a French writer, born at Montauban, 1709. He cultivated the muses, and his tragedy of Dido raised him to the rank of a poet, little inferior to Racine. He became member of the French academy 1760, and pronounced at his admission a discourse in favour of christianity, by proving that the man of religion and virtue is the only true philosopher, which drew upon him the ridicule of the profligate philosophers of the times; of Voltaire, Helvetius, and their associates. This drove him from Paris to his estate, where he spent the rest of his days employed in philosophy and religion, and died there of an apoplexy, 1784. His works consist of dramatic pieces—moral discourses—sacred odes—An imitation of the Georgics—voyage de Languedoc, &c.

POMPILIUS, a grammarian of Syria, who opened a school at Rome, and had Cicero and Cæsar among his pupils. See **NUMA**.

POMPILIA, a daughter of Numa Pompilius. She married Numa Martius, by whom she had Ancus Martius, the fourth king of Rome.

POMPONIA. The most remarkable of this name is the wife of Q. Cicero, sister to Pomponius Atticus. She punished with the greatest cruelty Philologus, the slave who had betrayed her husband to Antony, and she ordered him to cut his flesh by piece-meal, and afterwards to boil it and eat it in her presence.

POMPONIUS, a celebrated Roman, intimate with Cicero. He was surnamed Atticus, from his long residence at Athens. (See **ATTICUS**.) 2. A Roman who accused Manlius the dictator of cruelty. He triumphed over Sardinia, of which he was made governor. He escaped from Rome, and the tyranny of the triumvirs, by assuming the habit of a pretor, and by travelling with his servants disguised in the dress of lictors with their fasces. 3. Secundus, an officer in Germany in the age of Nero. He was honoured with a triumph for a victory over the barbarians of Germany. He wrote some poems greatly celebrated by the ancients for their beauty and elegance.—This name was common to many other illustrious Romans.

POMPONATIUS (Peter), an eminent Italian, born at Mantua, 1462. He taught philosophy at Padua and Bologna with the highest reputation. In his book *De Immortalitate Animæ*, he observes, that the immortality of the soul cannot be proved by philosophical reasons; he, however, thought it proper to add, that as an article of faith, he believed in it. This precaution did not save him, and he was persecuted as an atheist. He died in 1525.

POMPOUS. *a.* (pompeux, Fr.) Splendid; magnificent; grand (*Pope*).

POMPOUSLY. *ad.* (from *pompous*.) Magnificently; splendidly (*Dryden*).

POMPOUSNESS. *s.* (from *pompous*.) Magnificence; splendour; showiness; ostentatiousness (*Addison*).

POMUM ADAMI. (*pomum*, an apple; so called because it was thought to have originated in consequence of Adam having eaten the forbidden fruit.) The protuberance in the anterior part of the neck, formed by the fore part of the thyroid cartilage.

PONÆA, in botany, a genus of the class octandria, order tryginia. Calyx five-parted; corol four-petalled; capsule three-celled, three-winged; the cells one-seeded. One species, a Guiana tree, with abruptly pinnate leaves, and terminal racemes.

POND. *s.* (supposed to be the same with *pound*; *runðan*, Saxon, to be shut up.) A small pool or lake of water; a basin; water not running or emitting any stream (*Woodward*).

To **POND.** *v. a.* To ponder: obsolete.

POND (Fish). In making fish-ponds it is generally agreed that those grounds are best which are full of springs, and apt to be moorish, for while the springs will breed the stock well, the marshiness will preserve them from being stolen: and it has been observed, that ponds which receive the stale and dung of horses and other cattle breed the largest and fattest fishes.

Lebault, Dubravius, and others, however, advise us to make choice of such place for a pond as may be refreshed with a little rill, or with rain-water running or falling into it; by which fishes are more inclined both to breed, are refreshed and fed the better, and prove of a much sweeter and more pleasant taste.

Such pools, again, as are large and have most gravel, and shallows where they may sport themselves at liberty, afford fishes of the purest taste. And observe, that in all pools it is best to allow some retiring place; as hollow banks, or shelves, or roots of trees to keep the stock from danger; and, when they think fit, from the extreme heat of summer, or the extreme cold of winter. Yet if many trees be suffered to overhang your pond, the frequency and number of their leaves falling into the water will make the water nauseous to the fishes, and the taste of the fishes nauseous to the eater.

Tench and eel love mud; the carp loves a gravelly ground, and in the hot months to feed on grass. Cleanse your pond, if you intend either profit or pleasure, once every three or four years, and let it lie dry six or twelve months, as well to kill the water-weeds, as water lilies, candoeks, and bulrushes that breed there, as that grass may grow in the pond's bottom, which carp will eat greedily in all the hot months if the pond be clean. The letting your pond dry and sowing oats in the bottom is also a good plan, for the fishes feed the faster.

Lebault also advises, that if your ponds be not very large and roomy, you often feed your fishes by throwing into them chippings of bread, curds, grains, or the entrails of chickens or of any other fowl. He affirms that frogs and ducks do much harm, and devour both the spawn and the young fry of all fishes, especially of the carp.

Carp and tench thrive and breed best when no other fish is put with them into the same pond; for all other fishes devour their spawn, or at least the greatest part of it. When you store your pond, put into it two or three melters to one spawner, if it be a breeding-pond; but if a nurse-pond, or feeding-pond, in which they will not breed, then no care need to be taken, whether there be most male or female carp.

It is observed, that the best ponds to breed carps are those that are stony or sandy, and are warm, and free from wind, and that are not deep, but have willow trees and grass on their sides, over which the water does sometimes flow: and note, that carps do more usually breed in marle-pits, or pits that have clean clay bottoms, or in new ponds, or ponds that lie dry a winter season, than in old ponds, that be full of weeds.

The best way to make the pond head secure, is to drive in two or three rows of stakes about six feet long, at about four feet distance from each other, the whole length of the head, the first row of which is to be rammed, at least, four feet deep, that they may stand strong and sure. And if you happen to find the bottom false, especially if it consists of a running-sand, you may besides lay the foundation with quicklime, which upon slacking will make it as hard as a stone.

Then dig your pond, and cast the earth among the piles and stakes, and when they are well covered over, drive in another row or two over them, ramming in the earth in the void spaces, that it may lie close and keep in the water; and so you may continue stakes upon stakes, ramming in the earth till your pond head be of the height you designed it.

The inside of the dam must be very smooth and straight, that no current may have power over it.

If the pond carries six feet water, it is enough; but it must be eight feet deep, to receive the freshes and rains that should fall into it.

It would also be advantageous, as we have already observed, to have shoals on the sides, for the fishes to sun themselves on, and lay their spawn on; besides which you should allow them a few hollow banks, shelves, roots of trees, islands, &c. to serve as their retiring places. In a breeding pond never expect any large carp, for the greatness of the number of the spawn will overstock the pond, and a store-pond has always been accounted the best for large carp.

If you would make a breeding-pond become a store-pond, first determine what quantity of carp it will contain, and then put in either all melters, or all spawners, by which means in a

little time you may have carp that are both large and are exceeding fat; for by putting in but one sex you prevent the possibility of their increase; yet the roach will, notwithstanding, multiply abundantly.

In disposing of the principal waters, you must remember to reserve some for the head quarters of the fishes, from which you may take, or in which you may put, any ordinary quantity. You should also have stews, and other auxiliary waters, so that you may convey any part of the stock from one to the other, by which means you will never want, and need never abound; and will lose no time in the growth of the fish, but employ the water, as land is employed, to the best advantage.

The condition of the place must determine the quantity of the ground to be covered with water. For example: we may propose, perhaps, in all fifteen acres in three ponds; or eight acres in two, and less there should not be; and these ponds should be placed one above another, so that the point of the lower may almost reach the upper: which contrivance is no less beautiful than advantageous. The head, or bank, which by stopping the current is to raise the water, and so make a pond, must be built with clay and earth, taken out of the pan or hollow digged in the lowest ground above the bank; and this pan should be shaped as a half oval, the flat of which reaches the bank, and the longer diameter runs square from it.

TO PONDER. *v. a.* (*pondero*, Latin.) To weigh mentally; to consider; to attend (*Bacon*).

TO PONDER. *v. n.* To think; to muse; with *on*. Improper use (*Dryden*).

PONDERABLE. *a.* (from *pondero*, Lat.) Capable to be weighed; measurable by scales (*Brown*).

PONDERAL. *a.* (from *pondus*, Latin.) Estimated by weight; distinguished from numeral (*Arbuthnot*).

PONDERATION. *s.* (from *pondero*, Latin.) The act of weighing (*Arbuthnot*).

PONDERER. *s.* (from *ponder*.) He who ponds.

PONDEROSITY. *s.* (from *ponderous*.) Weight; gravity; heaviness (*Brown*).

PONDEROUS. *a.* (*ponderosus*, Latin.) 1. Heavy; weighty (*Bacon*). 2. Important; momentous (*Shaks*). 3. Forceful; strongly impulsive (*Dryden*).

PONDEROUS SPAR, in mineralogy. See **BARYTES**.

PONDEROUSLY. *ad.* (from *ponderous*.) With great weight.

PONDEROUSNESS. *s.* (from *ponderous*.) Heaviness; weight; gravity (*Boyle*).

PONDESTURIA, a town of Italy, in Monterrat, seated on the S. side of the Po, 33 miles E. of Turin. Lon. 8. 25 E. Lat. 45. 2 N.

PONDICHERRY, a town of Hindustan, on the coast of Coromandel, settled by the French in 1674. Previously to the war of 1756, it was, perhaps, the finest city in India.

It extended along the sea-coast above a mile, and was three quarters of a mile in breadth. It was well built, and, beside many public buildings, had a citadel, then the best of its kind in India. This city was taken by the English, in 1761, and immediately razed, in retaliation of M. Lally's conduct toward Fort St. David, in 1758. It was restored in 1763; taken by the English in 1778; restored in 1783; and again taken by the English in 1793. It is 100 miles S. of Madras. Lon. 80. 0 E. Lat. 11. 56 N.

PON'ENT. *a.* (*ponente*, Italian.) Western (Mong).

PONG-HOU, islands in the China Sea, which lie E. of the coast of Fokien, and form an archipelago between the part of Emouy and the island of Formosa. They are only sand banks or rocks; and not a shrub is to be seen upon them. The harbour in the principal island is good, and sheltered from every wind. A Chinese garrison is kept here, with one of the mandarins called literati, whose chief employment is to watch the trading vessels to and from China and Formosa. Lon. 121. 25 E. Lat. 23. 30 N.

PONGO, in mastiology. See **SIMIA**.

PONIARD. *s.* (*poignard*, Fr.) A dagger; a short stabbing weapon (*Dryden*).

To **PONIARD.** *v. a.* (*poignardier*, Fr.) To stab with a poniard.

PONK. *s.* A nocturnal spirit; a hag (*Spenser*).

PONS, a town of France, in the department of Lower Charente, famous in the time of the Huguenots. It has a mineral spring, and is seated on a hill, near the river Seigne, 10 miles S. of Saintes. Lon. 0. 30 W. Lat. 45. 36 N.

PONS (St.), a town of France, in the department of Herault. It was a bishop's see before the revolution, and is seated in a valley surrounded by mountains, in which are fine marble quarries. It is 24 miles N. of Narbonne. Lon. 2. 47 E. Lat. 43. 29 N.

PONS VAROLII. In anatomy. *Corpus annulare.* *Processus annularis.* Eminentia annularis. Varolius's bridge. An eminence of the medulla oblongata, first described by Varolius. It is formed by the two exterior crura of the cerebellum becoming flattened and passing over the crura of the cerebrum.

PONTÁ DELGADA, a seaport of St. Michael, one of the Azores. It is defended by a citadel; and contains about 8,000 inhabitants. Lon. 25. 40 W. Lat. 37. 45 N.

PONTAFELLA. See **PONTEFA**.

PONTAGE. *s.* (*ponts*, *pontis*, a bridge.) Duty paid for the reparation of bridges.

PONT-A-MOUSSON, a considerable town of France, in the department of Meurthe, with a university. There were lately several religious houses, and the premonstrantes had a magnificent church here. It is seated on the Moselle, which divides it into two parts, two miles N.W. of Nanci. Lon. 6. 16 E. Lat. 48. 43 N.

PONT-ARLIER, an ancient town of France,

in the department of Jura, seated on the river Doubs, near Mount Jura. It is a commodious passage into Swisserland, and is defended by a strong castle. Lon. 6. 26 E. Lat. 46. 55 N.

PONT-AUDEMER, a town of France, in the department of Eure, seated on the Rille, 13 miles E. of Honfleur, and 85 N.W. of Paris. Lon. 0. 35 E. Lat. 49. 21 N.

PONT-DE-CE, a town of France, in the department of Maine and Loire, seated on the Loire, three miles from Angers, and 178 S.W. of Paris. Lon. 0. 29 W. Lat. 47. 25 N.

PONT-DE-L'ARCHE, a town of France, in the department of Eure, with a castle. It is seated on the Seine, over which is a bridge, five miles N. of Louviers, and 62 N.W. of Paris. Lon. 1. 15 E. Lat. 49. 5 N.

PONT-DE-VAUX, a town of France, in the department of Ain, seated on the Ressousse, eight miles S. of Macon. Lon. 4. 55 E. Lat. 46. 28 N.

PONT-DE-VESLE, a town of France, in the department of Ain. It has a manufacture of stuffs called Augustines, and also of tapestry for the coverings of arm-chairs and sofas, of the same kind as those of Ambusson. It is seated on the Vesle, 12 miles W. of Bourg. Lon. 5. 4 E. Lat. 46. 16 N.

PONT-DU-GARD. See **GARD**.

PONTE-DE-LIMA, a town of Portugal, in Entre-Douero-e-Minho, with a palace. It is seated on the Lima, over which is a magnificent bridge, 13 miles N.W. of Braga, and 190 N. of Lisbon. Lon. 8. 44 W. Lat. 41. 51 N.

PONTE-STURA, a town of Italy, in Montferrat, seated at the confluence of the Stura and Po, three miles S.W. of Casal.

PONTERERIA, in botany, a genus of the class hexandria, order monogynia. Corol one-petal, six-cleft, two-lipped; stamens three, inserted three in the tip, and three in the tube of the corol; capsule three-celled. Six species; aquatics of the East or West Indies. See Nat. Hist. Pl. CXL.

PONTEFA, or **PONTAFELLA**, a town of Germany, in Carinthia, seated on the Fella, over which is a bridge that leads to the best passage over the Alps. It is 20 miles N.W. of Friuli. Lon. 13. 0 E. Lat. 46. 25 N.

PONTEFRAC, a borough in the W. riding of Yorkshire, with a market on Saturday. It is situate in a very rich soil, and noted for its large plantations of licorice. Its castle, now in ruins, has been the scene of various tragical events in the English history, particularly the murder of the unfortunate Richard II. It is governed by a mayor, sends two members to parliament, and is 22 miles S.W. of York, and 175 N.N.W. of London. Lon. 1. 18 W. Lat. 53. 42 N.

PONTELAND, a village in Northumberland, on the river Blythe, seven miles N. E. of Newcastle. It was a Roman station, called Pons Ælii; and here, in 1244, a peace was concluded between Henry III. and the king of Scotland.

P O N

PONTIANA, a river of Borneo, which enters the ocean by several mouths, at the west side of the island, under the equinoctial line, where the Dutch have a factory.

PONTICUM MARE, the sea of Pontus, generally called the Euxine.

PONTIFF. *s.* (*pontifex*, Latin.) 1. A priest; a high priest (*Bacon*). 2. The pope.

PONTIFICAL. *a.* (*pontificalis*, Latin.) 1. Belonging to a high priest. 2. Popish (*Baker*). 3. Splendid; magnificent (*Shakspeare*). 4. (from *pons* and *facio*.) Bridge-building.

PONTIFICAL. *s.* (*pontificale*, Latin.) A book containing rites and ceremonies ecclesiastical (*Stillingfleet*).

PONTIFICALLY. *ad.* (from *pontifical*.) In a pontifical manner.

PONTIFICATE. *s.* (*pontificatus*, Latin.) Papacy; popedom (*Addison*).

PONTIFICE. *s.* (*pons* and *facio*.) Bridge-work; edifice of a bridge (*Milton*).

PONTIFICIAN. *a.* (from *pontiff*.) Adhering to the pope; popish (*White*).

PONTIUS. The most celebrated of this name is—Herennus, a general of the Samnites, who surrounded the Roman army under the consuls T. Veturius and P. Posthumus. He made the Roman army pass under the yoke, but was afterwards conquered, and obliged in his turn to pass under it. Fabius Maximus defeated him, when he appeared again at the head of another army, and he was afterwards shamefully put to death by the Romans, after he had adorned the triumph of the conqueror.

PONTIVY, a town of France, in the department of Morbihan, with a linen manufacture; seated on the river Blavet, 25 miles N. of Vannes.

PONTLEVIS. *s.* A disorderly action of a horse in disobedience to his rider, in which he rears up several times running (*Bailey*).

PONTOISE, a town of France, in the department of Seine and Oise, with a castle. In 1435, the English took it by stratagem; and Charles VII. retook it by storm in 1442. The parliament of Paris was transferred to this place in 1652, 1720, and 1753. It is seated on an eminence, near the Oise, 27 miles N.W. of Paris. Lon. 2. 6 E. Lat. 49. 3 N.

PONTON, or **PONTOON**, in war, denotes a little floating bridge made of boats and planks. The ponton is a machine consisting of two vessels, at a little distance, joined by beams, with planks laid across for the passage of the cavalry, the cannon, infantry, &c. over a river, or an arm of the sea, &c. The late-invented ponton is of copper, furnished with an anchor, &c. to fix to it. To make a bridge, several of these are disposed two yards asunder, with beams across them; and over those are put boards or planks. They are also linked to each other, and fastened on each side the river by a rope run through a ring in each of their heads, and fixed to a tree or stake on either shore; the whole makes one firm uniform bridge, over which a train of artillery may pass.

P O O

PONTREMOLI, a town of Tuscany, with a strong castle; seated at the foot of the Apennines, on the river Magra, 55 miles N.N.W. of Pisa. Lon. 9. 40 E. Lat. 44. 25 N.

PONTUS, a kingdom of Asia Minor, bounded on the east by Colchis, west by the Halys, north by the Euxine sea, and south by Armenia. It was governed by kings, and was in its most flourishing state under Mithridates the Great: it at length became a Roman province, and under the emperors a regular governor was always appointed over it. 2. A part of Mysia in Europe on the borders of the Euxine sea, where Ovid was banished. 3. An ancient deity, father of Phorcys, Thanmas, Nereus, Eurybia and Ceto by Terra. He is the same as Oceanus. (*Apollod.*).

PONTUS EUXINUS. See **EUXINUS**.

PONTYPOOL, a town in Monmouthshire, with a market on Saturday, and a manufacture of japanned ware. It is seated between two hills, on the river Avon, 15 miles S.W. of Monmouth, and 149 W. by N. of London.

PONY. *s.* A small horse.

PONZA, a small island in the Mediterranean, near the coast of Naples, at the entrance of the gulf of Gaeta; containing a town, harbour, and considerable salt-works. Lon. 13. 10 E. Lat. 40. 53 N.

PONZONE, a town of Piedmont, in the duchy of Montferrat, 10 miles S. of Acqui, and 18 N. of Savona.

POOL. *s.* (*pul*, Saxon.) A lake of standing water (*Burnet*).

POOLE (Matthew), an English divine, born at York, in 1624, and educated at Oxford. He became rector of St. Michael le Quern, London, from whence he was ejected in 1662, for nonconformity. He wrote against popery, but his greatest works are his Annotations, and his Synopsis Criticorum, in 5 vols. folio, London, 1669. He died at Amsterdam in 1679.

POOLE, a borough and seaport in Dorsetshire, with a market on Monday and Thursday. It is a country of itself, governed by a mayor, and situate on a peninsula projecting into a capacious bay, which branches into many creeks, and forms several islands. The harbour admits vessels of moderate size only; but for them it is very secure. Poole rose into some consequence, when the ancient town of Wareham fell into decay. The principal branch of business here is the Newfoundland fishery. It has also a large importation of deals from Norway, a general commerce with America and various parts of Europe, and a fine coasting trade, particularly in corn and coal. Near the mouth of the harbour is an oyster bank, from which vast quantities are carried, to be fattened in the creeks of Essex and the Thames. Poole is 40 miles W.S.W. of Winchester, and 105 W. by S. of London, Lon. 1. 59 W. Lat. 50. 43 N.

POOLORON, or **POLERON**, one of the Banda islands, 100 miles S.E. of Amboyna. Lon. 130. 0 E. Lat. 4. 20 S.

POOLOWOY, one of the Banda islands,

on which the Dutch have a regular pentagon, called Fort Revenge.

POONA, a town of Hindustan, in Visapour, and the capital of the Western Mahratta empire. It is not large, and entirely defenceless; the chief seat of power being at Poorunder. It is 100 miles S.E. of Bombay. Lon. 73. 55 E. Lat. 18. 30 N.

POOP, the stern of a ship, or the highest, uppermost, and hinder part of the ship's hull.

POOR, *a.* (*pauvre*, French; *povre*, Spanish.)

1. Not rich; indigent; necessitous; oppressed with want (*Pope*). 2. Trifling; narrow; of little dignity, force, or value (*Bacon*). 3. Paltry; mean; contemptible (*Davies*). 4. Unimportant (*Swift*). 5. Unhappy; uneasy; pitiable (*Waller*). 6. Mean; depressed; low; dejected (*Bacon*). 7. (A word of tenderness.) Dear (*Prior*). 8. (A word of slight contempt.) Wretched (*Baker*). 9. Not good; not fit for any purpose (*Shakespeare*). 10. *The Poor*. Those who are in the lowest rank of the community; those who cannot subsist but by the charity of others (*Sprat*). 11. Barren; dry; as, a poor soil. 12. Lean; starved; emaciated (*Ben Jonson*). 13. Without spirit; flaccid.

POOR LAWS. Of the general outline of this most enormous and almost ineffectual burden on the people, much has been said in the excellent treatise of Mr. Colquhoun. The 43 of Elizabeth, c. 2, is the foundation of all that is good in the poor laws; making provision for finding work for the industrious and able; for compelling the idle and able to labour; and for affording relief to the diseased and impotent: and the 13, 14 Charles II. c. 12, is the foundation of all that is evil, by forming the system of settlements and removals; a system, establishing oppression, litigation, and expense, and which has been made more oppressive, and more productive of litigation and expense by every subsequent statute, till the statute of the 35th of his present majesty; which, by forbidding removals in case the pauper is not absolutely chargeable, has remedied more than half the evils occasioned by the former laws.

Overseers.—The churchwardens of every parish, with two, three, or four substantial householders, according to the size of the parish, to be nominated in Easter week, or within a month after, under the hands and seals of two or more neighbouring justices, and who shall be called overseers of the poor. 43 Elizabeth, c. 2, s. 1.

Where there are no churchwardens, the whole power is vested in the overseers, 17 George II. c. 38, s. 15.

Overseer dying, or becoming incapable of acting, two justices may appoint another. *Ibid.* s. 3. If any person shall find himself aggrieved by any act of the justices, Ap.* sessions, whose determination shall be final. *Ibid.* s. 6.

Where there is no nomination of overseers, P. 51. on every justice of the division. R. by distress from the sessions, to be levied by the churchwardens and overseers. 43 Elizabeth, c. 2, s. 10.

* In this article the following abbreviations will be used: P. denotes penalty; R. the mode of recovering it; A. the application; Ap. the appeal; J. 1 or 2, and W. 1 or 2, justices or witnesses.

Parish officers, with consent of two justices, shall set children to work, whose parents cannot maintain them, and all persons, married or single, who cannot maintain themselves, and have no regular trade or calling; and one justice may send persons to the house of correction who will not work; and the parish officers, not having an excuse, to be allowed by two justices, shall meet once in a month, at least, in the church on a Sunday after evening service, to consult. P. 20s. R. distress, and, in default, commitment till paid. J. 2. A. the poor. Ap. sessions. *Ibid.* s. 1, 2, 6, 11.

Overseers, within four days after the end of their year, shall account to two justices of all sums received and paid, and pay over what remains to their successors; who, in default, may levy it by distress, under warrant of two justices; who, in default of distress, may commit till paid. *Ibid.* s. 2, 4.

Every parish officer neglecting to obey the regulations of the above act, P. 40s. to 51. R. distress. J. 2. A. the poor. 17 George II. c. 38, s. 14.

Parish officer neglecting his duty, or disobeying the warrant of a justice, P. 40s. R. distress, and, in default, commitment not exceeding ten days. J. 2. A. the poor. Ap. sessions, giving ten days notice. 33 George III. c. 55, s. 1, 2.

Rate.—Parish officers shall raise by a rate on all the inhabitants, a stock of flax, &c. to set the poor to work, and sums for the relief of the old and lame who are not able to work, and for apprenticing poor children. Rate to be made by consent of two justices. 43 Elizabeth, c. 2, s. 1.

Parish officers shall cause notice to be given publicly in the church, of such consent of the justices, the next Sunday; and no rate shall be collected till such notice is given. 17 George II. c. 3, s. 1. They shall permit the inhabitants to inspect such rates at all reasonable hours, on payment of 1s.; and give copies on payment of 6d. for every twenty-four names. P. 20s. A. to the party aggrieved. *Ibid.* s. 2, 3.

Persons aggrieved by assessment, Ap. sessions, 17 George II. c. 38, s. 4.

Goods of persons refusing to pay, may be distrained in any part of the county; and of any other county, on oath made before a justice of such other county, which oath shall be certified in the warrant. Ap. to the sessions of the county where the assessment was made. *Ibid.* s. 7.

If two justices perceive that the inhabitants of any parish are not able to levy money sufficient for the relief of the poor, they shall assess any neighbouring parish within the hundred, in aid; and if the hundred shall not be of sufficient ability, then any parishes within the county. 43 Elizabeth, c. 2, s. 3.

Father, grandfather, mother, or grandmother, of persons wanting relief, shall maintain them; P. 20s. per month. R. distress, and, in default, commitment till paid. J. 2. A. the poor. *Ibid.* s. 2, 11.

Fathers leaving their wives and children, and mothers their children, chargeable to the parish, having ability to maintain them, the parish officers, where such are left, may, by warrant of two justices, seize so much of the goods and chattels, or receive so much of the annual rent as such justices shall appoint, to reimburse the parish; and such order to be confirmed by the sessions, 5 George I. c. 8, s. 1.

P O O R L A W S.

Parish officers, with consent of the lord of the manor, may, by order of two justices, erect cottages on waste lands, for the poor. 43 Elizabeth, c. 2. s. 5.

They may also, with consent of two justices, set up trades, &c. for the employment of the poor. 3 Charles II. c. 4, s. 22.

Relief.—Parish officers, with consent of the majority of the inhabitants, may contract with any person for the lodging, keeping, maintaining, and employing the poor; and persons refusing such relief are not entitled to any other. 9 George I. c. 7, s. 4.

The abominable oppression of this execrable law has, however, been removed by another humane statute of the present reign; for by 36 George III. c. 25, s. 1, 2, 3, it is enacted, that it shall be lawful for the parish officers, with the approbation of one justice in writing, to relieve any industrious person at his own habitation, under certain circumstances of temporary illness or distress; and one justice may order such relief for any time not exceeding one month, provided the cause be written on the back of the order, which the parish officers are bound to obey; and two justices may continue such order from time to time, each period in succession not being more than one month.

A justice, or a medical man, or clergyman, by warrant of a justice, may visit workhouses, and examine the state of them, and hear complaints, and certify to the sessions; and if there should be any infectious disorder, the visiting justice shall apply to another justice, or any other person visiting, to two justices; which two justices shall order such regulations as they deem necessary, till the next sessions. 30 George III. c. 49, s. 1, 2.

Names of persons receiving parish relief to be entered in a book. 3 William, c. 11, s. 11. And no other person to be relieved but by order of a justice. *Ibid.*

No relief to be ordered by a justice unless for a reasonable cause, proved on oath, and unless the pauper shall have first applied to a parish officer or a vestry, nor before the justice shall have summoned the parish officers. 9 George I. c. 7, s. 1.

The name of such person to be entered with the others; and no parish officer, except on sudden emergency, shall bring any charge on the parish for persons not so registered. P. 51. R. distress. J. 2. A. poor. *Ibid.* s. 2.

Persons receiving relief to be badged on the shoulder with a large Roman P, and the initial of the name of the parish. P. forfeiture of the relief, or commitment for not above twenty-one days. J. 1. And on every peace officer who shall relieve any person not so badged, 20s. R. distress. J. 1. A half to the informer, half to the poor. 8, 9 William, c. 3, s. 2.

Settlements.—The general heads on which settlements are founded are, birth, apprenticeship, service, serving offices, renting 10l. per annum, marriage, and estate.

1. **Birth.**—Children, *primâ facie*, whether bastard or legitimate, are settled where born: but with respect to bastards, if a woman goes collusively to be delivered in another parish, the child gains no settlement there.

Bastards born during an order of removal, or the suspension of it, belong to the mother's parish. 35 George III. c. 101, s. 6. And so of bastards born in vagrancy. 17 George II. c. 5, s. 25. And so if born in houses of industry in incorporated districts. 20 George III. c. 36. Or in friendly

societies. 33 George III. c. 54, s. 25. Or in lying-in hospitals. 13 George III. c. 82.

Legitimate children are settled as their parents, till old enough to gain a settlement of their own; the earliest period of which is seven years: at which age, by 5 Elizabeth, c. 5, s. 12, a child may be apprenticed to a person using the seas; and by 17 George II. c. 5, justices may bind the child of a vagrant of the same age; and any apprentice gains a settlement in a place where he has resided as such for forty days.

2. **Apprenticeship.**—The time required to gain a settlement has just been mentioned. The apprentice must be legally bound, except that the contract not being indented, which is fatal to the legality in every other case, is not in this. 31 George II. c. 11.

3. **Service.**—Unmarried person without children hired and serving for a year, gains a settlement, 3 William c. 11. But must continue a whole year in such service. 8, 9 William, c. 30. Serving a certificated member of a benefit society no settlement. 33 George III. c. 54, s. 24. Forty days residence in the place necessary, but they need not be all together. Where the last forty days are in different places, settlement where the servant slept the last night. General hiring deemed hiring for a year. Hiring for a year, with liberty to be absent at harvest, sheep-shearing, &c. gains no settlement; but to serve a month in the militia does. Hiring for one day short of a year no settlement. Serving for three hundred and sixty-five days, if leap-year, no settlement. Hiring at so much per week, conditionally to part at a month's warning, deemed a general hiring; and, as such, a hiring for a year.

4. **Serving Offices.**—Persons coming to inhabit a place, and executing any annual and public office for a year, settlement. 3 William, c. 11, s. 6.

5. **Renting 10l. per annum.**—This gains a settlement, if resided on forty days. 13, 14 Charles II.

6. **Marriage.**—As a general rule, the wife follows the husband's settlement; but if the husband has no settlement, or it is not known at his death, her own settlement is restored. And if the husband deserts his wife, her settlement remains.

7. **Estate.**—No person shall be removed from any estate while he remains on it. 9 George I. c. 7. But no person gains a settlement by any estate whose purchase was less than 30l. *Ibid.*

Persons who have no settlement, as foreigners, or whose settlement cannot be known, as deserted infants, must be kept by the parish where they happen to be.

Certificates.—This head is almost done away by the salutary law which will be noticed under.

Removals.—So much of 13, 14 Charles II. c. 12, as enables justices to remove persons likely to become chargeable, is repealed; and no person can now be removed till actually chargeable. 35 George III. c. 101, s. 1.

Justices may suspend removal of persons ill; either under a vagrant pass, or order of removal; expense attending the suspension to be paid by the parish officers of the place to which the pauper is to be removed; on refusal to pay within three days, R. distress and sale, with costs, not exceeding 40s. J. 1. If out of the jurisdiction, warrant of distress to be backed by a justice having jurisdiction. Ap. to the sessions, if charges and costs exceed 20l. *Ibid.* s. 2.

Every person convicted of larceny or felony, or deemed a rogue and vagabond, or disorderly per-

POOR'S RATE.

son, or who shall appear to two justices, on oath of one witness, to be a person of evil fame or a reputed thief, and shall not give a satisfactory account of himself and way of living; and every unmarried woman with child, shall be deemed actually chargeable, and be removed as such. *Ibid.* s. 6.

Persons refusing to go with an order of removal, or returning when removed, P. commitment as a vagabond. J. 1. 13, 14 Charles II. c. 12, s. 3.

Parish officer refusing to receive a person so sent, P. bound to the assizes or sessions, to answer the contempt. J. 1. *Ibid.*

If removed into another county or jurisdiction, and the parish officers refuse to receive, P. 5l. A. to the poor of the place from which the pauper is removed. R. distress, and, in default, commitment for forty days. J. 1. of the jurisdiction to which removed. W. 2. 3 William, c. 11, s. 10.

Appeal from orders of removal to the sessions of the county from which the pauper was removed. 8, 9 William, c. 30, s. 6. It must be to the sessions of the county, and not of any corporate town.—(*Brit. Ency.*)

POOR'S RATE, an assessment raised throughout England and Wales, for the temporary relief, or permanent maintenance, of all such persons, as from age, infirmity, or poverty, cannot themselves procure the means of subsistence. The first statute, or law made in England, which gives any particular directions concerning paupers, was 11 Henry VII. c. 2. it directs, "That every beggar, not able to work, shall resort to the hundred where he last dwelt, is best known, or was born; and shall there remain, upon pain of being set in the stocks, three days and three nights, with only bread and water, and then shall be put out of town." The insufficiency of this regulation soon became evident, and in 1531 an act was passed whereby the justices of every county were empowered to grant licences to poor, aged, and impotent persons, to beg within a certain precinct; but if they were found begging without licence, or beyond the limits specified, they were either to be whipped or set in the stocks. This however was a very inadequate mode of providing for the poor; and in 1536 an act was passed directing the governors and magistrates of counties, towns, and parishes, to provide for every aged, poor, and impotent person, who should have dwelt three years in any place, by means of the voluntary alms of charitable persons, which were to be collected for this purpose, in every parish. The act likewise directed, that sturdy vagabonds should be compelled to work, and that children from five to fourteen years of age, who lived in idleness, and were found begging, should be put to service.

Upon the destruction of the monasteries, from the charities of which the poor had derived their principal support, some further ineffectual attempts were made for their relief, by means of voluntary donations; but it was at length found necessary to stimulate public charity by a compulsory clause, in an act passed in 1563. This act directed, that if any parishioner shall obstinately refuse to pay reasonably towards the relief of the poor, or should discourage others, the justices of the peace, at their quarter-sessions, might tax him to a reasonable weekly sum, which if he refused to pay, they might commit him to prison. This may be considered as the origin of the poor's rate, which was rendered more general by an act passed in 1572, which directed that assessments should be made of the parishioners of every parish,

for the relief of the poor of the same parish; which was the first regular and effectual parochial assessment for the poor in England. In 1601, further regulations were adopted on this subject; it being enacted by 43 Elizabeth, c. 2. that every parish should be bound to provide for its own poor; and that overseers of the poor should be annually appointed, who, with the church-wardens, should raise, by a parish rate, competent sums for this purpose: the mode in which the assessment was directed to be made was, that the justices of the peace of every county or place corporate, or the major part of them, at the general sessions to be held after Easter following, and so yearly, as often as they should think fit, should rate every parish to such a weekly sum of money as they should think convenient; which sum, so taxed, was to be yearly assessed by an agreement of the parishioners within themselves, or in default thereof, by the churchwardens and petty constables, or by an order of the justices of the peace: and if any person refused or neglected to pay the portion of money so taxed, it might be levied by distress, and in default thereof, the person to be committed to prison till the money was paid. In this mode, or with very little variation, the poor's-rate has continued to be annually levied; but, as from the increase of population, the advanced price of all the necessaries of life, and other causes, the number of the poor has been greatly augmented, the sum raised for their support has progressively advanced to a very important magnitude.

According to an estimate, published by Dr. Davenant, of the sum raised by the poor's-rate in England and Wales, in the latter part of the reign of Charles II. it amounted to 665,362l. As the number of the poor increased, it not only became necessary to raise a greater sum for their maintenance, but new cases arose with respect to the claims of individuals to this kind of relief, in consequence of which various acts were passed for explaining and amending the laws for the relief of the poor. In 1735, the house of commons appointed a committee to consider of the existing laws relative to the maintenance and settlement of the poor, and what further provisions might be necessary for their better relief and employment. The committee came to several resolutions, which were agreed to by the house; the most important were, "that the laws in being, relating to the maintenance of the poor of this kingdom, are defective; and, notwithstanding they impose heavy burdens on parishes, yet the poor, in most of them, are ill taken care of;" and that it was very expedient, that the laws relating to the poor should be reduced into one act of parliament.

In 1776, a return was ordered to be made to parliament of the total expenditure on account of the poor, for one year, ending at Easter; pursuant to which, accounts were received from 14,113 parishes or places in England and Wales, from which it appeared, that the aggregate sum expended was 1,530,804l. 6s. 3d. and that there were then 1970 workhouses, capable of accommodating 89,775 persons. In 1786, a return was again ordered to be made of the average annual expenditure of the three preceding years, when accounts were obtained from 14,240 parishes or places, and the total was found to have increased in the short period of ten years to 2,004,238l. 5s. 11d. since which time a still greater increase has taken place.

In the year 1803, an act was passed for procuring returns relative to the expense and maintenance of the poor; from the answers and returns

POP

made pursuant thereto, the following particulars are derived.

Out of 14,611 parishes and places from which accounts were received, 3765 parishes maintain all, or part of, their poor in workhouses. The number of persons so maintained during the year, ending Easter 1803, was 85,468; and the expense, incurred therein, amounted to 1,016,445l. 15s. 3d. being at the rate of 12l. 3s. 6½d. for each person maintained in that manner.

The number of persons relieved out of workhouses was 956,248, besides 194,052, who were not parishioners. The expense, incurred in the relief of the poor not in workhouses, amounted to 3,061,446l. 16s./10½d. A large proportion of those, who were not parishioners, appear to have been vagrants, and it is probable that the relief given to this class of poor could not exceed two shillings each, amounting to 19,405l. 4s. This sum being deducted from the above 3,061,446l. 16s. 10½d. leaves 3,042,041l. 12s. 10½d. being at the rate of 3l. 3s. 7½d. for each parishioner relieved out of any workhouse.

The number of persons relieved in and out of workhouses was 1,039,716, and as the resident population of England and Wales, in the year 1801, appeared from the returns made under the population act to have been 8,872,980, the number of parishioners relieved from the poor's-rate appears to be twelve in a hundred of the resident population.

The expenditure, in suits of law, removal of paupers, and expenses of overseers and other officers, amounted to 190,072l. 17s. ½d. and the sum expended in purchasing materials for employing the poor to 47,523l. 11s. 4½d.

The poor of 293 parishes are stated in the returns to be farmed, or maintained under contract; and the poor of 764 parishes are maintained and employed under the regulations of special acts of parliament.

The total sum, raised by the poor's-rate, and other parochial rates within the year, ending Easter 1803, was 5,348,205l. 9s. 3¾d. The average rate in the pound was, in England 4s. 4½d. and in Wales 7s. 1½d. the average of England and Wales 4s. 5¼d. (*British Ency.*)

POORLY. *ad.* (from *poor*.) 1. Without wealth (*Sidney*). 2. Not prosperously; with little success (*Bacon*). 3. Meanly; without spirit (*Shakspeare*). 4. Without dignity (*Wotton*).

POORNESS. *s.* (from *poor*.) 1. Poverty; indigence; want (*Burnet*). 2. Meanness; lowness; want of dignity (*Addison*). 3. Sterility; barrenness (*Bacon*).

POORSPIRITED. *a.* (*poor* and *spirit*.) Mean; cowardly (*Dennis*).

POORSPIRITEDNESS. *s.* Meanness; cowardice (*South*).

POORUNDER, a fortress of Hindustan, in Visiapour, seated on a mountain, 18 miles E.S.E. of Pooná. It is the place of refuge for that capital in case of an invasion; and here the archives of government are kept.

POP. *s.* (*poppysma*, Lat.) A small smart quick sound. Formed from the sound (*Addison*).

To POP. *v. n.* (from the noun.) To move or enter with a quick, sudden, and unexpected motion (*Swift*).

POP

To POP. *v. a.* 1. To put out or in suddenly, silyly, or unexpectedly (*Shakspeare*). 2. To shift (*Locke*).

POPA MADRE, a town of Terra Firma, with a convent and chapel of the Virgin, to which the Spaniards in those parts go in pilgrimage, especially those who have been at sea. It is seated on a high mountain, 50 miles E. of Carthagená. Lon. 74. 32 W. Lat. 10. 15 N.

POPAYAN, a province of New Granada, in the W. part of that kingdom. A chain of barren mountains runs through the country from N. to S.; and the soil near the sea is flat, marshy, and often flooded by the rains.

POPAYAN, the capital of a province of that name in New Granada, and a bishop's see, with a university. The trade is considerable, and the inhabitants are estimated at 25,000. It stands in a large plain, 230 miles W.S.W. of St. Fe de Bogota, and 240 N.E. of Quito. Lon. 75. 55 W. Lat. 2. 35 N.

POPE, PAPA, FATHER, the sovereign pontiff, or supreme head of the Romish church. The appellation of pope was anciently given to all Christian bishops; but about the latter end of the eleventh century, in the pontificate of Gregory VII. it was usurped by the bishop of Rome, whose peculiar title it has ever since continued. The spiritual monarchy of Rome sprung up soon after the declension of the Roman empire. This sovereign is addressed under the term holiness, and in the council of the Lateran held under Innocent III. he was declared ordinary of ordinaries. The pope was an absolute monarch in his Italian dominions, and his power was very considerable; being able, in case of necessity, to put fifty thousand men into the field, besides his naval strength in galleys. The French revolution, which has reversed all order, and overthrown every government where its power extended, and substituted a barbarous and military tyranny in its place, has greatly impaired the splendour, dignity, and power of the pope; nor shall we be at all surprised to see the papal throne entirely reversed, and the territories added to some of the subordinate kingdoms lately erected by the usurper of France.

POPE (Alexander), an illustrious English poet, born 8th June, 1688, in the Strand, where his father was a hatter. He learned writing by imitating printed books, and at eight was placed under a priest named Taverner, under whom he learned Latin and Greek. At 12 he went to live with his parents at Binfield, in Windsor Forest, and first discovered his taste for poetry by reading Ogilby's Virgil and Sandys' Ovid; but the writings of Spenser, Waller, and Dryden, now became his favourite employment. He early tried his strength in poetry, and it is said that at the age of 10 he converted some of the stories of Homer into a play, which his schoolfellows acted with the assistance of his master's gardener, who undertook Ajax. His first regular composition was his Ode on Solitude; but his Pastorals, begun in 1704, introduced him soon as a promising

bard to the wits of the age, especially Wycherley and Walsh. In 1704, he wrote his first part of *Windsor Forest*, completed six years after, and inscribed to lord Lansdown. The *Essay on Criticism* appeared in 1708, and in this incomparable performance, though not yet 20 years old, he evinced all the genius and judgment of the most mature reflection. The fame of the essay was soon surpassed by the *Rape of the Lock*, in 1712. The poet chose for his subject the conduct of lord Petre in cutting off a lock of Mrs. Fermor's hair; and he had the happiness, by the delicate effusions of his muse, to effect a reconciliation between the offended parties. The *Temple of Fame* next appeared, and in 1713 he published proposals for a translation of Homer's *Iliad*. This was generously supported, and the poet received from subscribers 6000*l.* besides 1200*l.* from the bookseller Lintot for the copy. Thus raised to independence, Pope purchased a house at Twickenham, where he removed his father and mother, 1715. In 1717 he published a collection of his poems; but in his edition of Shakspeare, in 1721, he consulted his private emolument more than his fame. He attempted the *Odyssey* with Broome and Fenton, whose labours he rewarded with 500*l.* and he received the same subscription as before, but only 600*l.* from the bookseller. In 1725 he joined Swift and Arbuthnot in writing some miscellanies, and in 1727 he published his *Dunciad*, with notes by Swift, under the name of Scriblerus. This singular poem owed its origin to the illiberal remarks to which the poet had been exposed from the scriblers of the day. As a composition, the *Dunciad* is a work of great merit; and Cibber himself, the hero of the piece, declares that nothing was ever more perfect and finished in its kind. The principles, however, of the poet must be condemned: if it was justice to retort abuse on those who had offended him, it was the most profligate conduct to hang up to immortal ignominy men of genius, talents, and respectability, who instead of censuring him had been loud in his praise. Lord Bolingbroke in 1729 entreated him to turn his thoughts to moral subjects, and this produced his *Essay on Man*, a work of acknowledged merit, containing a system of ethics. In his ethic epistles, it is supposed that he reflected, in the character of Timon, on the duke of Chandos; and this propensity was unfortunately indulged in his satires, which he continued till 1739, and in which he censures, in the severest language, persons of the highest rank. In 1742, the poet gave to the world a fourth book of his *Dunciad*, and prepared a more perfect edition of his works; but death stopped his hand. His constitutional attack of the head-ach increased by a dropsy in the breast, baffled all relief, and he expired 30th May 1744, aged 56. He made, by his will, Miss Blount heiress to his property during her life, and he bequeathed all his works to his friend Warburton, who accordingly, in 1751, published a complete edition of the whole, in 9 vols. 8vo. A very

interesting essay on his writings and genius appeared in 1756, and in 1782 by Dr. Warton, and it was again reprinted with a new edition of his works in 1797. Though a catholic in religion, Pope was little more than a deist, as his *Essay on Man* fully justifies; yet in the latter part of his life he attended the English church. In his person he was little and somewhat crooked: he was capricious in his friendships; and though he was courted by men of rank and fashion, by lords Harcourt, Bolingbroke, and others, distinguished for opulence, as well as celebrity and wit, yet he never forgot the homage which should be paid to the man of poetical eminence. His manners, as lord Orrery has observed, were delicate, easy, and engaging; he treated his friends with a politeness that charmed, and a generosity that was much to his honour. Every guest was made happy within his doors; pleasure dwelt under his roof, and elegance presided at his table.

Dr. Johnson gives a view of the intellectual character of Pope, and draws a most exquisite parallel between Dryden and him. For particulars, however, we must refer our readers to Johnson's *Lives of the Poets*, vol. 4. *Life of Pope*.

POPE, or POPE JOAN, a game on playing cards somewhat similar to that of matrimony. It is played by a number of people, who generally use a board painted for this purpose, which may be purchased at most turners or toy shops.

The eight of diamonds must first be taken from the pack, and after settling the deal, shuffling, &c. the dealer dresses the board by putting fish, counters or other stakes one each to ace, king, queen, knave, and game; two to matrimony, two to intrigue, and six to the nine of diamonds, stiled pope. This dressing is in some companies at the individual expence of the dealer, though in others the players contribute two stakes a piece towards the same. The cards are next to be dealt round equally to every player, one turned up for trump, and about six or eight left in the stock to form stops: as for example, if the ten of spades is turned up, the nine consequently becomes a stop; the four kings and the seven of diamonds are always fixed stops, and the dealer is the only person permitted in the course of the game to refer occasionally to the stock for information what other cards are stops in that respective deal. If either ace, king, queen, or knave, happen to be the turned-up trump, the dealer takes whatever is deposited on that head; but when pope is turned up, the dealer is entitled both to that and the game, besides a stake for every card dealt to each player. Unless the game is determined by pope being turned up, the eldest hand begins by playing out as many cards as possible; first the stops, then pope if he have it, and afterwards the lowest card of his longest suit, particularly an ace, for that never can be led through; the other players are to follow when they can, in sequence of the same suit, till a stop occurs, and the party having the said stop, thereby becomes eldest

hand, and is to lead accordingly, and so on, until some person parts with all his cards, by which he wins the pool (game), and becomes entitled besides to a stake for every card not played by the others, except from any one holding pope, which excuses him from paying; but if pope has been played, then the party having held it is not excused. King and queen form what is denominated matrimony, queen and knave make intrigue, when in the same hand; but neither they, nor ace, king, queen, knave, or pope, entitle the holder to the stakes deposited thereon, unless played out, and no claim can be allowed after the board is dressed for the succeeding deal; but in all such cases the stakes are to remain for future determination.

This game only requires a little attention to recollect what stops have been made in the course of the same; as for instance, if a player begin by laying down the eight of clubs, then the seven in another hand forms a stop, whenever that suit is led from any lower card, or the holder when eldest may safely lay it down in order to clear his hand.

PO'PEDOM. *s.* (pope and dom.) Papacy; papal dignity (*Shakspeare*).

PO'PERY. *s.* (from *pope*.) The religion of the church of Rome (*Swift*).

The following summary, extracted chiefly from the decrees of the council of Trent, continued under Paul III. Julius III. and Pius IV. from the year 1545 to 1563, by successive sessions, and the creed of pope Pius IV. subjoined to it, and bearing date November 1564, may not be unacceptable to the reader. One of the fundamental tenets, strenuously maintained by popish writers, is the infallibility of the church of Rome; though they are not agreed whether this privilege belongs to the pope or a general council, or to both united; but they pretend that an infallible living judge is absolutely necessary to determine controversies, and to secure peace in the Christian church. However, Protestants allege, that the claim of infallibility in any church is not justified by the authority of scripture; much less does it pertain to the church of Rome; and that it is inconsistent with the nature of religion, and the personal obligations of its professors; and that it has proved ineffectual to the end for which it is supposed to be granted, since popes and councils have disagreed in matters of importance, and they have been incapable, with the advantage of this pretended infallibility, of maintaining union and peace.

Another essential article of the popish creed is the supremacy of the pope, or his sovereign power over the universal church. Further, the doctrine of the seven sacraments is a peculiar and distinguishing doctrine of the church of Rome: these are baptism, confirmation, the eucharist, penance, extreme unction, orders, and matrimony.

The council of Trent (sess. 7. can. 1.) pronounces an anathema on those who say, that the sacraments are more or fewer than seven, or that any one of the above number is not truly

and properly a sacrament. And yet it does not appear that they amounted to this number before the 12th century, when Hugo de St. Victore and Peter Lombard, about the year 1144, taught that there were seven sacraments. The council of Florence, held in 1438, was the first council that determined this number. These sacraments confer grace, according to the decree of the council of Trent (sess. 7. can. 8.) *ex opere operato*, by the mere administration of them: three of them, viz. baptism, confirmation, and orders, are said (can. 9.) to impress an indelible character, so that they cannot be repeated without sacrilege; and the efficacy of every sacrament depends on the intention of the priest by whom it is administered. (can. 11.) Pope Pius expressly enjoins, that all these sacraments should be administered according to the received and approved rites of the Catholic church. With regard to the eucharist in particular, we may here observe, that the church of Rome holds the doctrine of transubstantiation; the necessity of paying divine worship to Christ under the form of the consecrated bread, or host; the propitiatory sacrifice of the mass, according to their ideas of which Christ is truly and properly offered as a sacrifice as often as the priest says mass; it practises likewise solitary mass, in which the priest alone, who consecrates, communicates, and allows communion only in one kind, viz. the bread, to the laity. Sess. 14.

The doctrine of merits is another distinguishing tenet of popery; with regard to which the council of Trent has expressly decreed (sess. 6. can. 32.) that the good works of justified persons are truly meritorious; deserving not only an increase of grace, but eternal life, and an increase of glory; and it has anathematized all who deny this doctrine. Of this same kind is the doctrine of satisfactions; which supposes that penitents may truly satisfy, by the afflictions they endure under the dispensations of providence, or by voluntary penances to which they submit, for the temporal penalties of sin, to which they are subject, even after the remission of their eternal punishment. Sess. 6. can. 30. and sess. 14. can. 8. and 9. In this connection we may mention the popish distinction of venial and mortal sins; the greatest evils arising from the former are the temporary pains of purgatory; but no man, it is said, can obtain the pardon of the latter without confessing to a priest, and performing the penances which he imposes.

The council of Trent (sess. 14. can. 1.) has expressly decreed, that every one is accused who shall affirm that penance is not truly and properly a sacrament, instituted by Christ in the universal church, for reconciling those Christians to the divine majesty who have fallen into sin after baptism: and this sacrament, it is declared, consists of two parts, the matter and the form; the matter is the act of the penitent, including contrition, confession, and satisfaction; the form of it is the act of absolution on the part of the priest. Accordingly it is enjoined, that it is the duty of every

P O P E R Y.

man, who hath fallen after baptism, to confess his sins once a year, at least, to a priest: that this confession is to be secret; for public confession is neither commanded nor expedient: and that it must be exact and particular, including every kind and act of sin, with all the circumstances attending it. When the penitent has so done, the priest pronounces an absolution; which is not conditional or declarative only, but absolute and judicial. This secret, or auricular confession, was first decreed and established in the fourth council of Lateran, under Innocent III. in 1215. (cap. 21.) And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent; which ordains, that confession was instituted by Christ, that by the law of God it is necessary to salvation, and that it has been always practised in the Christian church. As for the penances imposed on the penitent by way of satisfaction, they have been commonly the repetition of certain forms of devotion, as pater-nosters, or avemarias, the payment of stipulated sums, pilgrimages, fasts, or various species of corporal discipline. But the most formidable penance, in the estimation of many who have belonged to the Romish communion, has been the temporary pains of purgatory. But under all the penalties which are inflicted or threatened in the Romish church, it has provided relief by its indulgences, and by its prayers or masses for the dead, performed professedly for relieving and rescuing the souls that are detained in purgatory.

Another article that has been long authoritatively enjoined and observed in the church of Rome, is the celibacy of her clergy. This was first enjoined at Rome by Gregory VII. about the year 1074, and established in England by Anselm archbishop of Canterbury about the year 1175; though his predecessor Lanfranc had imposed it upon the prebendaries and clergy that lived in towns. And though the council of Trent was repeatedly petitioned by several princes and states to abolish this restraint, the obligation of celibacy was rather established than relaxed by this council; for they decreed, that marriage contracted after a vow of continence is neither lawful nor valid; and thus deprived the church of the possibility of ever restoring marriage to the clergy. For, if marriage, after a vow, be in itself unlawful, the greatest authority upon earth cannot dispense with it, nor permit marriage to the clergy, who have already vowed continence.

To the doctrines and practices above recited may be further added the worship of images, of which protestants accuse the papists. But to this accusation the papist replies, that he keeps images by him to preserve in his mind the memory of the persons represented by them; as people are wont to preserve the memory of their deceased friends by keeping their pictures. He is taught (he says) to use them so as to cast his eyes upon the pictures or images, and thence to raise his heart to the things represented, and there to employ it in meditation,

love, and thanksgiving, desire of imitation, &c. as the object requires.

These pictures or images have this advantage, that they inform the mind by one glance of what in reading might require a whole chapter; there being no other difference between them, than that reading represents leisurely and by degrees; and a picture, all at once. Hence he finds a convenience in saying his prayers with some devout pictures before him, he being no sooner distracted, but the sight of these recalls his wandering thoughts to the right object; and as certainly brings something good into his mind, as an immodest picture disturbs his heart with filthy thoughts. And because he is sensible that these holy pictures and images represent and bring to his mind such objects as in his heart he loves, honours, and venerates; he cannot but upon that account love, honour, and respect the images themselves.

The council of Trent likewise decreed, that all bishops and pastors who have the cure of souls do diligently instruct their flocks, that it is good and profitable to desire the intercession of saints reigning with Christ in heaven. And this decree the papists endeavour to defend by the following observations. They confess that we have but one Mediator of redemption; but affirm that it is acceptable to God that we should have many mediators of intercession. Moses (say they) was such a mediator for the Israelites; Job for his three friends; Stephen for his persecutors. The Romans were thus desired by St. Paul to be his mediators; so were the Corinthians, so the Ephesians, *Ep. ad Rom. Cor. Eph.*; so almost every sick man desires the congregation to be his mediators, by remembering him in their prayers. And so the papist desires the blessed in heaven to be his mediators; that is, that they would pray to God for him. But between these living and dead mediators there is no similarity; the living mediator is present, and certainly hears the request of those who desire him to intercede for them; the dead mediator is as certainly absent, and cannot possibly hear the requests of all those who at the same instant may be begging him to intercede for them, unless he be possessed of the divine attribute of omnipresence; and he who gives that attribute to any creature is unquestionably guilty of idolatry. And as this decree is contrary to one of the first principles of natural religion, so does it receive no countenance from scripture, or any Christian writer of the three first centuries. Other practices peculiar to the papists are the religious honour and respect that they pay to sacred relics; by which they understand not only the bodies and parts of the bodies of the saints, but any of those things that appertained to them, and which they touched; and the celebration of divine service in an unknown tongue: to which purpose the council of Trent hath denounced an anathema on any one who shall say that mass ought to be celebrated only in the vulgar tongue; sess. 25. and sess. 22. can. 9. Though the council of Lateran under

Innocent III. in 1215, (can. 9.) had expressly decreed, that because in many parts within the same city and diocese there are many people of different manners and rites mixed together, but of one faith, the bishops of such cities or dioceses should provide fit men for celebrating divine offices, according to the diversity of tongues and rites, and for administering the sacraments.

We shall only add, that the church of Rome maintains, that unwritten traditions ought to be added to the holy Scriptures, in order to supply their defect, and to be regarded as of equal authority; that the books of the Apocrypha are canonical scripture; that the vulgar edition of the Bible is to be deemed authentic; and that the scriptures are to be received and interpreted according to that sense which the holy mother church, to whom it belongs to judge of the true sense, hath held, and doth hold, and according to the unanimous consent of the fathers.

Such are the principal and distinguishing doctrines of popery, most of which have received the sanction of the council of Trent, and that of the creed of pope Pius IV. which is received, professed; and sworn to by every one who enters into holy orders in the church of Rome; and at the close of this creed we are told that the faith contained in it is so absolutely and indispensably necessary, that no man could be saved without it.

POPESEYE. *s.* (*pope* and *eye*.) The gland surrounded with fat in the middle of the thigh.

POPGUN. *s.* (*pop* and *gun*.) A gun with which children play, that only makes a noise (*Cheyne*).

POPILIUS. This name was common to many eminent Romans, the most conspicuous of whom is Lænas, a Roman ambassador to Antiochus, king of Syria. He was commissioned to order the monarch to abstain from hostilities against Ptolemy, king of Egypt, who was an ally of Rome. Antiochus wished to evade him by his answers, but Popilius, with a stick which he had in his hand, made a circle round him on the sand, and bade him in the name of the Roman senate and people not to go beyond it before he spoke decisively. This boldness intimidated Antiochus; he withdrew his garrisons from Egypt, and no longer meditated a war against Ptolemy.

POPINJAY, in ornithology. See **PSITTACUS**.

POPINJAY, is used by Shakspeare, to denote a trifling fop.

POPISH. *a.* (from *pope*.) Taught by the pope; relating to popery (*Hooker*).

POPISHLY. *ad.* With tendency to popery; in a popish manner (*Pope*).

POPLAR. See **POPULUS**.

POPLES. In anatomy. The ham or joint of the knee.

POPLITEAL ARTERY. (from *poples*, the ham.) The continuation of the crural artery, through the hollow of the ham.

POPLITEUS. From *poples*, the ham.

POPPY (Red corn). See **PAPAYER ERATICUM**.

POPPY (White). See **PAPAYER ALBUM**.

POPULACE. *s.* (*populace*, Fr. from *populus*, Lat.) The vulgar; the multitude (*Swift*).

POPULACY. *s.* (*populace*, French.) The common people; the multitude (*Decay of Piety*).

POPULAR. *a.* (*populaire*, Fr. *popularis*, Lat.) 1. Vulgar; plebeian (*Milton*). 2. Suitable to the common people; familiar; not critical (*Hooker*). 3. Beloved by the people; pleasing to the people (*Clarendon*). 4. Studious of the favour of the people (*Addison*). 5. Prevailing or raging among the populace: as, a popular distemper.

POPULARITY. *s.* (*popularitas*, Latin.) 1. Graciousness among the people; state of being favoured by the people (*Dryden*). 2. Representation suited to vulgar conception; what affects the vulgar (*Bacon*).

POPULARLY. *ad.* (from *popular*.) 1. In a popular manner; so as to please the crowd (*Dryden*). 2. According to vulgar conception (*Brown*).

To POPULATE. *v. n.* (from *populus*, Lat.) To breed people (*Bacon*).

POPULATION. *s.* (from *populate*.) The state of a country with respect to numbers of people (*Bacon*).

As we are not satisfied with any of the theories which have been proposed on this interesting subject, we shall simply place here a few results; and leave our readers to theorize as they please.

The population of Great Britain was long a subject of great uncertainty, both with respect to the actual number of inhabitants, and their increase or diminution. But many of the doubts have been removed, by the act for ascertaining the population of Great Britain, passed on the last day of the year 1800: it directed a general enumeration of houses, families, and persons; and the proper officers of the several parishes and places were ordered to take the account, on the 10th of March, 1801, in England and Wales; and in Scotland as soon as possible after that day. This difference was necessary, because in the colder climate of Scotland it was not certain that all parts of the country would be easily accessible so early in the year. An abstract of the returns was laid before both houses of parliament; and the summary of the enumeration, though unavoidably defective in some points, may be stated generally, as follows:

POPULATION.

	HOUSES.			PERSONS.		
	Inhabited.	By how many families occupied.	Uninhabited.	Males.	Females.	Total.
England.....	1,472,873	1,787,520	53,965	3,987,935	4,343,499	8,331,434
Wales	108,053	118,333	3,511	257,178	284,368	541,546

The islands of Guernsey, Jersey, Alderney, and Sark, the Scilly Islands, and the Isle of Man, were not comprised in the enumeration; the total population of these islands has been usually estimated at about 80,000. The number of houses in Ireland has been nearly ascertained by the collection of a hearth-money tax, from whence it has been computed that the population of that part of the united kingdom somewhat exceeds four millions of persons. Therefore, with a very moderate allowance for those places from which no returns were received, and for omissions in others, the total population of the united kingdom of Great Britain and Ireland amounted to 15,100,000 persons.

At the beginning of the preceding century, Dr. Davenant published an account of the total number of houses in England and Wales, according to the hearth books of Lady Day 1690; this account was probably as correct as the above, and a comparison of them shows an increase from 1690 to 1801 of 261,708 houses, which at $5\frac{1}{2}$ persons to a house makes an increase of 1,465,563 persons. This appears to be the least increase that can have taken place, but it has certainly been greater on account of the number of soldiers and seamen far exceeding those employed in 1690.

A circumstance which caused considerable disagreement in the estimates, which previously to the enumeration, had been formed on this subject, was the want of sufficient accounts to determine the proportion of persons to a house. Dr. Davenant and Dr. Brakenridge reckoned six persons to a house; while Mr. G. King allowed rather more than $4\frac{1}{2}$ in London, $4\frac{1}{3}$ in the cities and market towns, and four in the villages. Dr. Price asserted that six persons to a house for London, and five to a house for all England, was too large an allowance; but the fact now appears to be, that in England and Wales the proportion is $5\frac{1}{2}$ persons to a house, and in Scotland $5\frac{1}{3}$.

The proportion of inhabitants to a house differs very considerably in some of the counties of England: the chief cause of this difference is the large towns, and particularly the sea-

ports which some of them contain, as in such places the inhabitants live more crowded together than in moderate sized inland towns. The difference in this respect between large towns and those of less extent will be shown with tolerable accuracy by the following statements.

Inhabitants.	Towns.	Persons to a House.
864,845 ..	London.....	$7\frac{1}{2}$
84,920 ..	Manchester	6 $\frac{1}{2}$
77,653 ..	Liverpool	6 $\frac{1}{2}$
63,645 ..	Bristol	6
43,194 ..	Plymouth	$9\frac{1}{2}$
32,200 ..	Bath	$7\frac{1}{2}$
32,166 ..	Portsmouth	6
29,516 ..	Hull	6 $\frac{1}{2}$
28,366 ..	Newcastle.....	9

The other towns in England containing upwards of twenty thousand inhabitants, are the following:

Inhabitants.	Towns.	Persons to a House.
73,670 ..	Birmingham.....	5
53,162 ..	Leeds.....	$4\frac{1}{2}$
36,832 ..	Norwich	$4\frac{1}{2}$
31,314 ..	Sheffield	$4\frac{1}{2}$
28,861 ..	Nottingham	$5\frac{1}{2}$

The latter are all manufacturing towns, the trade of which had for several years previously to the enumeration been in a very distressed situation, and had reduced the population much below its usual standard; a few years of peace will restore the inhabitants which these towns had lost, and reduce in some degree the population of the principal out-ports.

Proportion of persons to a house in towns of a moderate size.

Inhabitants.	Towns.	Persons to a House.
7,909 ..	Devizes	5
7,668 ..	Salisbury.....	$5\frac{1}{2}$
7,655 ..	Bury	$5\frac{1}{2}$
7,579 ..	Gloucester	$5\frac{1}{2}$
7,531 ..	Wellington.....	$5\frac{1}{2}$
7,398 ..	Lincoln	5
7,020 ..	Northampton.....	$5\frac{1}{2}$
6,828 ..	Hereford.....	5
6,730 ..	Newark	5
6,505 ..	Tiverton.....	$5\frac{1}{2}$
5,794 ..	Taunton	5

POPULATION.

Another enumeration was made in 1811, from the principal results of which, together with those of 1801, we are enabled to present the following comparative statement of the population of the several counties of Great Britain, in the years

1801 and 1811; showing the increase or diminution thereof: together with the present state of the returns called for by an act of the last session of parliament.

ENGLAND.

Remarks.—1. In order that the comparative statement of the population of the several counties in 1801 and 1811 might be made as perfect as the present state of the returns of 1811 permits, the few outstanding deficiencies have been supplied from the returns of 1801; and it is supposed that the uncertainty thence arising can scarcely amount to a thousand persons in any one of the few incomplete counties, excepting only in Monmouthshire. The apparent diminution in Banffshire chiefly arises from three parishes, being now returned wholly in neighbouring counties, which parishes in 1801 were

returned partly or wholly in Banffshire. 2. The number of males composing the army, navy, &c. includes the regular army, the artillery, and the British regular militia, all according to the latest returns to parliament; but the regiments of local militia, which were embodied for training and exercise on the 27th May, 1811, have been ascribed to their respective counties. With the navy are included the royal marines: and to all these are added the seamen employed in navigating registered vessels. 3. The larger abstracts, both of the enumeration and parish register returns, will be

presented to parliament when the respective returns shall have been completed; in furtherance of which purpose, letters and blank schedules have been dispatched to all the places where any deficiency is supposed to exist.

An attempt was made to ascertain the population of France, by command of the government, in the tenth year of the republic, but the account does not appear to have been very accurately taken. The total population of the 102 departments into which France was then divided was stated at 33,104,343 persons, over an extent of about 185,600 square miles. This account included thirteen departments incorporated with the north of France, four departments in the south, and some smaller acquisitions, comprehending in the whole 23,790 square miles, containing 5,114,419 inhabitants.

The following is a comparative view of the population of the principal sea ports and manufacturing towns of Great Britain, and of France.

POPULOSITY. *s.* (from *populous*.) Populousness; multitude of people (*Brown*).

POPULOUS. *a.* (*populosus*, Latin.) Full of people; numerous inhabited (*Milton*).

POPULOUSLY. *ad.* With much people.

POPULOUSNESS. *s.* (from *populous*.) The state of abounding with people (*Temple*).

POPULUS. Poplar. In botany, a genus of the class dioecia, order octandria. Calyx a lacinated scale of the ament; corol turbinate, oblique, entire.—Twelve species; natives of Europe and America; four of them of our own country. They are all cultivated for some purpose or other, and are as follow:

1. *P. alba*. White poplar. Found wild in our own woods; tall, straight, with a smooth whitish bark; leaves heart-roundish, lobed, toothed, white-downy underneath; aments ovate.

There are two varieties: the common white poplar; and the great white poplar, or abele.

2. *P. tremula*. Trembling poplar. Aspen. Found wild in our woods; its leaves trembling with every breath of wind, the plane of the long petioles being at right angles to that of their leaves, whence a peculiar freedom of motion.

3. *P. nigra*. Black poplar. Found in wa-

try places in our own country, and other parts of Europe. Its inner bark is used by the inhabitants of Kamschatka as a material for bread; and the downy cotton of its seeds has been sometimes employed for paper. The young buds, oculi, or rudiments of the leaves, which appear in the beginning of the spring, were formerly employed in an official ointment. At present they are almost entirely disregarded, though they should seem, from their sensible qualities, to be applicable to purposes of some importance. They have a yellow, unctuous, odorous, balsamic juice. The bark being lighter than cork serves to support fishing nets. The wood is not apt to splinter, and is hence occasionally used by turners; it also affords rafters, poles, and railing, and is employed for flooring in several counties.

4. *P. dilatata*. Lombardy poplar: approaching to the cypress in the compressed form of its growth. A native of Lombardy.

5. *P. balsamifera*. Tacamahac. This name is given to several other plants, and especially to the fagara octandra, and the calophyllum inophyllum. In truth, each of these yields a glutinous resin of a similar kind, which is sold under the name of gum-tacamahac in the shops; though the best is that obtained from *C. inophyllum*. See for the medical properties of this secretion the article **TACAMAHAC**. It is a native of America and Siberia.

6. *P. candicans*. Heart-leaved tacamahac poplar. This secretes also a resinous gum; and is a native of Canada.

7. *P. lavigata*. Smooth poplar. A native of North America: flowering in March and April.

8. *P. monilifera*. Canadian poplar. Indigenous to Canada: flowers in May.

9. *P. Græca*. Athenian poplar. Broad leaves; a native of the Archipelago: flowers in March and April.

10. *P. heterophylla*. Various-leaved poplar. Tree large; branches numerous; leaves broad. A native of Virginia and New York: flowers in April and May.

11. *P. angulata*. Carolina poplar. Covered with a light-green bark, like some sorts of willow, growing greyer as the tree advances in years. A large Carolina tree: flowering in March.

12. *P. canescens*. Hoary poplar; with large roundish leaves, hoary underneath. Found in watry places in our own country.

They may be all increased by cuttings, layers, or suckers. Most of the species may be usefully employed in dyeing; yielding to wool a good nut, fawn, nankeen, and similar grave colours, according to the quantity of wood employed and the length of time consumed in boiling.

PORA, an island in the Indian ocean, on the W. coast of Sumatra, 54 miles long, and from 9 to 12 broad. Lon. 98. 30 E. Lat. 1. 10 S.

PORANA, in botany, a genus of the class pentandria, order monogynia. Corol campanulate; calyx five-cleft, in fruit larger; style

semibifid, longer, permanent; stigma globular; pericarp two-valved. One species; a twining shrub of India.

PORCELAIN, a substance of a middle nature between pottery and glass, produced by an incipient fusion of the different earths that compose it, which are hereby rendered hard, sonorous, and semitransparent, and possess an imperfect conchoidal or vitreous fracture. See the article **POTTERY**.

PORCELAIN CLAY, in mineralogy. See **ARGILLA**.

PORCELAIN SHELL. See **CYPRÆA**.

PORCELLANITE, in mineralogy. See **JASPER**.

PORCH, in architecture, a kind of vestibule supported by columns; much used at the entrance of the ancient temples, halls, churches, &c. A porch, in the ancient architecture, was a vestibule, or a disposition of insulated columns usually crowned with a pediment, forming a covert place before the principal door of a temple or court of justice. Such was that before the door of St. Paul's, Covent-Garden, the work of Inigo Jones. When a porch had four columns in front, it was called a tetrastyle; when six, hexastyle; when eight, octostyle, &c.

PORCH, in Greek *γῶν*, a public portico in Athens, adorned with the pictures of Polygnottus and other eminent painters. It was in this portico that Zeno the philosopher taught; and hence his followers were called Stoics. See **STOICS** and **ZENO**.

PORCHESTER, a village in Hampshire, four miles N. of Portsmouth, at the upper end of the harbour, between Fareham and Portsea island. It has an ancient castle, which has served of late years for the reception of prisoners of war, and ordnance stores.

PORCIA, a sister of Cato, of Utica, greatly commended by Cicero. 2. A daughter of Cato, of Utica, who married Bibulus, and after his death, Brutus. She was remarkable for her prudence, philosophy, courage, and conjugal tenderness. So great was her firmness and constancy, that Brutus communicated to her the conspiracy which he and many other illustrious Romans had formed against J. Cæsar. Porcia wished them success, and dropped nothing which might affect the situation of the conspirators. When Brutus was dead she refused to survive him, and attempted to end her life as a daughter of Cato; and when she saw that every weapon was removed from her reach, she swallowed burning coals, and died about 48 years before the Christian era.

PORCO, a town of Peru, capital of a jurisdiction in the diocese of Plata. It has its name from a mountain, rich in silver, and its mine was the first worked by the Spaniards after the conquest. It is 25 miles W.S.W. of Potosi. Lon. 67. 20 W. Lat. 19, 40 S.

PORCUPINE, in mastiology. See **HYSTRIX**.

PORCUPINE MAN, the name by which one Edward Lambert, who had a distempered skin, went in London. We have the following ac-

count of him in the Philosophical Transactions for 1755, by Mr. Henry Baker, F. R. S. "He is now (says he) 40 years of age, and it is 24 years since he was first shown to the society. The skin of this man, except on his head and face, the palms of his hands, and the soles of his feet, is covered with excrescences that resemble an innumerable company of warts, of a brown colour and cylindrical figure; all rising to an equal height, which is about an inch, and growing as close as possible to each other at their bases; but so stiff and elastic as to make a rustling noise when the hand is drawn over them. These excrescences are annually shed, and renewed in some of the autumn or winter months. The new ones, which are of a paler colour, gradually rise up from beneath as the old ones fall off; and at this time it has been found necessary for him to lose a little blood, to prevent a slight sickness which he had been used to suffer before this precaution was taken. He has had the small pox, and he has been twice salivated, in hopes to get rid of this disagreeable covering; but though, just when the pustules of the small-pox had scaled off, and immediately after his salivations, his skin appeared white and smooth, yet the excrescences soon returned by a gradual increase, and his skin became as it was before. His health during his whole life has been remarkably good; but there is one particular of this case more extraordinary than all the rest: this man has had six children, and all of them had the same rugged covering as himself, which came on like his own about nine weeks after the birth. Of these children only one is now living, a pretty boy, who was shown with his father. It appears, therefore (as Mr. Baker remarks), that a race of people might be propagated by this man, as different from other men as an African is from an Englishman; and that if this should have happened in any former age, and the accidental original have been forgotten, there would be the same objections against their being derived from the same common stock with others: it must therefore be admitted possible, that the differences now subsisting between one part of mankind and another, may have been produced by some such accidental cause, long after the earth has been peopled by one common progenitor." See **HOMO** and **MAN**.

PORE. *s.* (*pore*, Fr. *poré*.) 1. Spiracle of the skin; passage of perspiration (*Bacon*). 2. Any narrow spiracle or passage (*Quincy*).

To PORE. *v. n.* To look with great intensesness and care; to examine with great attention.

POREBLIND. *a.* (*pore* and *blind*: commonly spoken and written *purbblind*.) Near-sighted; shortsighted (*Bacon*).

PORENTRU, a town of France, capital of the department of Mont Terrible. It lately belonged to Switzerland, and was the capital of the bishopric of Basel. It is seated on the Hallan, near Mount Jura, 24 miles W.S.W. of Basel. Lon. 7. 10 E. Lat. 47. 27 N.

PORI BILIARII, in anatomy, the biliary pores or ducts that receive the bile from the

P O R I S M.

penicilli of the liver, and convey it to the hepatic duct.

PORINESS. *s.* (from *pore*.) Fulness of pores (*Wiseman*).

PORISM, *porisma*, in geometry, has by some been defined a general theorem, or canon, deduced from a geometrical locus, and serving for the solution of other general and difficult problems. Proclus derives the word from the Greek *πορίστω*, I establish, and conclude from something already done and demonstrated: and accordingly he defines *porisma* a theorem drawn occasionally from some other theorem already proved: in which sense it agrees with what is otherwise called corollary.

Pappus says, a porism is that in which something was proposed to be investigated.

Others derive it from *πορος*, a passage, and make it of the nature of a lemma, or a proposition necessary for passing to another more important one.

But Dr. Simson, rejecting the erroneous accounts that have been given of a porism, defines it a proposition, either in the form of a problem or a theorem, in which it is proposed either to investigate or demonstrate.

Euclid wrote three books of porisms, being a curious collection of various things relating to the analysis of the more difficult and general problems. Those books however are lost; and nothing remains in the works of the ancient geometers concerning this subject besides what Pappus has preserved, in a very imperfect and obscure state, in his Mathematical Collections, viz. in the introduction to the 7th book.

Several attempts have been made to restore these writings in some degree, besides that which Pappus has left upon the subject. Thus, Fermat has given a few propositions of this kind; which are to be found in the collection of his works, in folio, 1679, pa. 116. The like was done by Bullialdus, in his *Exercitationes Geometricæ*, 4to. 1657. Dr. Robert Simson gave also a specimen, in two propositions, in the *Philos. Trans.* vol. 32, pa. 330; and besides left behind him a considerable treatise on the subject of porisms, which has been printed in an edition of his works, at the expense of the earl of Stanhope, in 4to. 1776.

The whole three books of Euclid were also restored by that ingenious mathematician Albert Girard, as appears by two notices that he gave, first in his *Trigonometry*, printed in French, at the Hague, in 1629, and also in his edition of the works of Stevinus, printed at Leyden in 1634, pa. 459; but whether his intention of publishing them was ever carried into execution I have not been able to learn.

A learned paper on the subject of porisms, by the very ingenious professor Playfair, has also been inserted in the 3d volume of the *Transactions of the Royal Society of Edinburgh*. As this paper contains a number of curious observations on the geometry of the ancients in general, as well as forms a complete treatise as it were on porism in particular, a pretty considerable abstract of it cannot but be deemed in this place very useful and important.

"The restoration of the ancient books of geometry (says the learned professor) would have been impossible without the coincidence of two circumstances, of which, though the one is purely accidental, the other is essentially connected with the nature of the mathematical sciences. The first of

these circumstances is the preservation of a short abstract of those books drawn up by Pappus Alexandrinus, together with a series of such lemmata as he judged useful to facilitate the study of them. The second is the necessary connection that takes place among the objects of every mathematical work, which, by excluding whatever is arbitrary, makes it possible to determine the whole course of an investigation when only a few points in it are known. From the union of these circumstances mathematics has enjoyed an advantage of which no other branch of knowledge can partake; and while the critic or the historian has only been able to lament the fate of those books of Livy and Tacitus which are lost, the geometer has had the high satisfaction to behold the works of Euclid and Apollonius reviving under his hands.

"The first restorers of the ancient books were not, however, aware of the full extent of the work which they had undertaken. They thought it sufficient to demonstrate the propositions which they knew from Pappus to have been contained in those books; but they did not follow the ancient method of investigation, and few of them appear to have had any idea of the elegant and simple analysis by which these propositions were originally discovered, and by which the Greek geometry was peculiarly distinguished.

"Among these few, Fermat and Halley are to be particularly remarked. The former, one of the greatest mathematicians of the last age, and a man in all respects of superior abilities, had very just notions of the geometrical analysis, and appears often abundantly skilful in the use of it; yet in his restoration of the *Loci Plani*, it is remarkable, that in the most difficult propositions he lays aside the analytical method, and contents himself with giving the synthetical demonstration. The latter, among the great number and variety of his literary occupations, found time for a most attentive study of the ancient mathematicians, and was an instance of, what experience shews to be much rarer than might be expected, a man equally well acquainted with the ancient and the modern geometry, and equally disposed to do justice to the merit of both. He restored the books of Apollonius, on the problem *De Sectione Spatii*, according to the true principles of the ancient analysis.

"These books, however, are but short, so that the first restoration of considerable extent that can be reckoned complete is that of the *Loci Plani* by Dr. Simson, published in 1749, which, if it differs at all from the work it is intended to replace, seems to do so only by its greater excellence. Thus much at least is certain, that the method of the ancient geometers does not appear to greater advantage in the most entire of their writings than in the restoration above mentioned; and that Dr. Simson has often sacrificed the elegance to which his own analysis would have led, in order to tread more exactly in what the lemmata of Pappus pointed out to him as the track which Apollonius had pursued.

"There was another subject, that of porisms, the most intricate and enigmatical of any thing in the ancient geometry, which was still reserved to exercise the genius of Dr. Simson, and to call forth that enthusiastic admiration of antiquity, and that unwearied perseverance in research, for which he was so peculiarly distinguished. A treatise in three books, which Euclid had composed on porisms, was lost, and all that remained

concerning them was an abstract of that treatise, inserted by Pappus Alexandrinus in his Mathematical Collections, in which, had it been entire, the geometers of later times would doubtless have found wherewithal to console themselves for the loss of the original work. But unfortunately, it has suffered so much from the injuries of time, that all that we can immediately learn from it is, that the ancients put a high value on the propositions which they called porisms, and regarded them as a very important part of their analysis. The porisms of Euclid are said to be, 'Collectio artificiosissima multarum rerum quæ spectant ad analysin difficiliorum et generalium problematum.' The curiosity, however, which is excited by this encomium is quickly disappointed; for when Pappus proceeds to explain what a porism is, he lays down two definitions of it, one of which is rejected by him as imperfect, while the other, which is stated as correct, is too vague and indefinite to convey any useful information.

"These defects might nevertheless have been supplied, if the enumeration which he next gives of Euclid's Propositions had been entire; but on account of the extreme brevity of his enunciations, and their reference to a diagram which is lost, and for the constructing of which no directions are given, they are all, except one, perfectly unintelligible. For these reasons, the fragment in question is so ob-scure, that even to the learning and penetration of Dr. Halley, it seemed impossible that it could ever be explained; and he therefore concluded, after giving the Greek text with all possible correctness, and adding the Latin translation, 'Hactenus porismatum descriptio nec mihi intellecta, nec lectori profutura. Neque aliter fieri potuit, tam ob defectum schematis cujus sit mentio, quam ob omnia quædam et transposita, vel aliter vitiata in propositionis generalis expositione, unde quid sibi velit Pappus haud mihi datum est conjicere. His adde dictio-nis modum nimis contractum, ac in re difficili, qualis hæc est, minime usurpandum.'

"It is true, however, that before this time, Fermat had attempted to explain the nature of porisms, and not altogether without success. Guiding his conjectures by the definition which Pappus censures as imperfect, because it defined porisms only 'ab accidente,' viz. 'porisma est quod deficit hypothesi a Theoremate Locali,' he formed to himself a tolerably just notion of these propositions, and illustrated his general description by examples that are in effect porisms. But he was able to proceed no farther; and he neither proved that his notion of a porism was the same with Euclid's, nor attempted to restore or explain any one of Euclid's propositions; much less did he suppose, that they were to be investigated by an analysis peculiar to themselves. And so imperfect indeed was this attempt, that the complete restoration of the porisms was necessary to prove, that Fermat had even approximated to the truth.

"All this did not, however, deter Dr. Simson from turning his thoughts to the same subject, which he appears to have done very early, and long before the publication of the *Loci Plani* in 1749.

"The account he gives of his progress, and of the obstacles he encountered, will be always interesting to mathematicians. 'Postquam vero apud Pappum legeram, Porismata Euclidis collectionem fuisse artificiosissimam multarum rerum, quæ spectant ad analysin difficiliorum et genera-

lium problematum, magno desiderio tenebar, aliquid de iis cognoscendi; quare sæpius et multis variisque viis tum Pappi propositionem generalem, mancā et imperfectā, tum primum lib. i.

'Porisma, quod solum ex omnibus in tribus libris integrum adhuc manet, intelligere et restituerē conabar; frustra tamen, nihil enim proficiebam. Cumque cogitationes de hac re multum mihi temporis consumperint, atque molestæ admodum evaserint, firmiter animum induxi hæc nunquam in posterum investigare; præsertim cum optimus geometra Halæius spem omnem de iis intelligendis abjecisset. Unde quoties menti occurrerant, toties eas arcebam. Postea tamen accidit, ut improvidum et propositi immemorem, invaserint, meque detinuerint donec tandem lux quædam effulserit, quæ spem mihi faciebat inveniendi saltem Pappi propositionem generalem, quam quidem multa investigatione tandem restitui. Hæc autem paulo post una cum Porismate primo lib. i. impressa est inter Transactiones Phil. anni 1723, num. 177.'

"The propositions mentioned, as inserted in the Philosophical Transactions for 1723, are all that Dr. Simson published on the subject of porisma during his life, though he continued his investigations concerning them, and succeeded in restoring a great number of Euclid's propositions, together with their analysis. The propositions thus restored form a part of that valuable edition of the posthumous works of this geometer which the mathematical world owes to the munificence of the late earl Stanhope.

"The subject of porisms is not, however, exhausted, nor is it yet placed in so clear a light as to need no farther illustration. It yet remains to enquire into the probable origin of these propositions, that is to say, into the steps by which the ancient geometers appear to have been led to the discovery of them.

"It remains also to point out the relations in which they stand to the other classes of geometrical truths; to consider the species of analysis, whether geometrical or algebraical, that belongs to them; and, if possible, to assign the reason why they have so long escaped the notice of modern mathematicians. It is to these points that the following observations are chiefly directed.

"I begin with describing the steps that appear to have led the ancient geometers to the discovery of porisms; and must here supply the want of express testimony by probable reasonings, such as are necessary, whenever we would trace remote discoveries to their sources, and which have more weight in mathematics than in any other of the sciences.

"It cannot be doubted, that it has been the solution of problems, which, in all states of the mathematical sciences, has led to the discovery of most geometrical truths. The first mathematical enquiries, in particular, must have occurred in the form of questions, where something was given, and something required to be done; and by the reasonings necessary to answer these questions, or to discover the relation between the things that were given, and those that were to be found, many truths were suggested, which came afterwards to be subjects of separate demonstration. The number of these was the greater, that the ancient geometers always undertook the solution of problems with a scrupulous and minute attention, which would scarcely suffer any of the collateral truths to escape their observation. We know,

PORISM.

from the examples which they have left us, that they never considered a problem as resolved, till they had distinguished all its varieties, and evolved separately, every different case that could occur, carefully remarking whatever change might arise in the construction, from any change that was supposed to take place among the magnitudes which were given.

"Now, as this cautious method of proceeding was not better calculated to avoid error, than to lay hold of every truth that was connected with the main object of enquiry, these geometers soon observed, that there were many problems which, in certain circumstances, would admit of no solution whatever, and that the general construction by which they were resolved would fail, in consequence of a particular relation being supposed among the quantities which were given.

"Such problems were then said to become impossible; and it was readily perceived, that this always happened, when one of the conditions prescribed was inconsistent with the rest, so that the supposition of their being united in the same subject, involved a contradiction. Thus, when it was required to divide a given line, so that the rectangle under its segment, should be equal to a given space, it was evident, that if this space was greater than the square of half the given line, the thing required could not possibly be done; the two conditions, the one defining the magnitude of the line, and the other that of the rectangle under its segments, being then inconsistent with one another. Hence an infinity of beautiful propositions concerning the maxima and the minima of quantities, or the limits of the possible relations which quantities may stand in to one another.

"Such cases as these would occur even in the solution of the simplest problems; but when geometers proceeded to the analysis of such as were more complicated, they must have remarked, that their constructions would sometimes fail, for a reason directly contrary to that which has now been assigned. Instances would be found where the lines that, by their intersection, were to determine the thing sought, instead of intersecting one another, as they did in general, or of not meeting at all, as in the above-mentioned case of impossibility, would coincide with one another entirely, and leave the question of consequence unresolved. But though this circumstance must have created considerable embarrassment to the geometers who first observed it, as being perhaps the only instance in which the language of their own science had yet appeared to them ambiguous or obscure, it would not probably be long till they found out the true interpretation to be put on it. After a little reflection, they would conclude, that since, in the general problem, the magnitude required was determined by the intersection of the two lines above mentioned, that is to say, by the points common to them both; so, in the case of their coincidence, as all their points must afford a solution; which solutions therefore must be infinite in number; and also, though infinite in number, they must all be related to one another, and to the things given, by certain laws, which the position of the two coinciding lines must necessarily determine.

"On enquiring farther into the peculiarity in the state of the data which had produced this unexpected result, it might likewise be remarked, that the whole proceeded from one of the condi-

tions of the problem involving another, or necessarily including it; so that they both together made in fact but one, and did not leave a sufficient number of independent conditions, to confine the problem to a single solution, or to any determinate number of solutions. It was not difficult afterwards to perceive, that these cases of problems formed very curious propositions, of an intermediate nature between problems and theorems, and that they admitted of being enunciated separately, in a manner peculiarly elegant and concise. It was to such propositions, so enunciated, that the ancient geometers gave the name of porisms.

"This deduction requires to be illustrated by examples." Mr. Playfair then gives several problems by way of illustration; one of which, which may here suffice to shew the method, is as follows:

"A triangle ABC being given, and also a point D, to draw through D a straight line DG, such, that, perpendiculars being drawn to it from the three angles of the triangle, viz. AE, BG, CF, the sum of the two perpendiculars on the same side of DG, shall be equal to the remaining perpendicular: or, that AE and BG together, may be equal to CF: pl. 139, fig. 8.

"Suppose it done: bisect AB in H, join CH, and draw HK perpendicular to DG.

"Because AB is bisected in H, the two perpendiculars AE and BG are together double of HK; and as they are also equal to CF by hypothesis, CF must be double of HK; and CL of LH. Now, CH is given in position, and magnitude; therefore the point L is given; and the point D being also given, the line DL is given in position, which was to be found.

"The construction was obvious. Bisect AB in H, join CH, and take HL equal to one third of CH; the straight line which joins the points D and L is the line required.

"Now, it is plain, that while the triangle ABC remains the same, the point L also remains the same, wherever the point D may be. The point D may therefore coincide with L; and when this happens, the position of the line to be drawn is left undetermined; that is to say, any line whatever drawn through L will satisfy the conditions of the problem. Here, therefore, we have another indefinite case of a problem, and of consequence another porism, which may be thus enunciated: 'A triangle being given in position, a point in it may be found, such, that any straight line whatever being drawn through that point, the perpendiculars drawn to this straight line from the two angles of the triangle which are on one side of it, will be together equal to the perpendicular that is drawn to the same line from the angle on the other side of it.

"This porism may be made much more general; for if, instead of the angles of a triangle, we suppose ever so many points to be given in a plane, a point may be found such, that any straight line being drawn through it, the sum of all the perpendiculars that fall on that line from the given points on one side of it, is equal to the sum of the perpendiculars that fall on it from all the points on the other side of it.

"Or still more generally, any number of points being given not in the same plane, a point may be found, through which if any plane be supposed to pass, the sum of all the perpendiculars which fall on that plane from the points on one side of it, is equal to the sum of all the perpendiculars that fall on the same plane from the points on the

PORISM.

other side of it. It is unnecessary to observe, that the point to be found in these propositions, is no other than the centre of gravity of the given points; and that therefore we have here an example of a porism very well known to the modern geometers, though not distinguished by them from other theorems."

After some examples of other porisms, and remarks upon them, the author then adds,

"From this account of the origin of porisms, it follows, that a porism may be defined, a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions."

"To this definition, the different characters which Pappus has given will apply without difficulty. The propositions described in it like those which he mentions, are, strictly speaking, neither theorems nor problems, but of an intermediate nature between both; for they neither simply enunciate a truth to be demonstrated, nor propose a question to be solved: but are affirmations of a truth, in which the determination of an unknown quantity is involved. In as far therefore as they assert, that a certain problem may become indeterminate, they are of the nature of theorems; and in as far as they seek to discover the conditions by which that is brought about, they are of the nature of problems."

"In the preceding definition also, and the instances from which it is deduced, we may trace that imperfect description of porisms which Pappus ascribes to the later geometers, viz. '*Porisma est quod deficit hypothesi a theoremate locali*.' Now, to understand this, it must be observed, that if we take the converse of one of the propositions called loci, and make the construction of the figure a part of the hypothesis, we have what was called by the ancients a local theorem. And again, if, in enunciating this theorem, that part of the hypothesis which contains the construction be suppressed, the proposition arising from thence will be a porism; for it will enunciate a truth, and will also require, to the full understanding and investigation of that truth, that something should be found, viz. the circumstance in the construction, supposed to be omitted."

"Thus when we say; if from two given points *E* and *D* (fig. 9), two lines *EF* and *FD* are inflected to a third point *F*, so as to be to one another in a given ratio, the point *F* is in the circumference of a circle given in position: we have a locus."

"But when conversely it is said; If a circle *ABC*, of which the centre is *O*, be given in position, as also a point *E*, and if *D* be taken in the line *EO*, so that the rectangle *EO. OD* be equal to the square of *AO*, the semidiameter of the circle; and if from *E* and *D*, the lines *EF* and *DF* be inflected to any point whatever in the circumference *BC*; the ratio of *EF* to *DF* will be a given ratio, and the same with that of *EA* to *AD*: we have a local theorem."

"And, lastly, when it is said; If a circle *ABC* be given in position, and also a point *E*, a point *D* may be found, such, that if the two lines *EF* and *FD* be inflected from *E* and *D* to any point whatever *F*, in the circumference, these lines shall have a given ratio to one another: the proposition becomes a porism."

"Here it is evident, that the local theorem is changed into a porism, by leaving out what relates to the determination of the point *D*, and of the given ratio. But though all propositions formed in this way, from the conversion of loci, be

porisms, yet all porisms are not formed from the conversion of loci. The first and second of the preceding, for instance, cannot by conversion be changed into loci; and therefore the definition which describes all porisms as being so convertible, is not sufficiently comprehensive. Fermat's idea of porisms, as has been already observed, was founded wholly on this definition, and therefore could not fail to be imperfect."

"It appears, therefore, that the definition of porisms given above agrees with Pappus's idea of these propositions, as far at least as can be collected from the imperfect fragments which contain his general description of them. It agrees also with Dr. Simson's definition, which is this: '*Porisma est propositio in qua proponitur demonstrare rem aliquam, vel plures datas esse, cui, vel quibus, ut et cuilibet ex rebus innumeris, non quidem datis, sed quæ ad eâ quæ data sunt eandem habent relationem, convenire ostendendum est affectionem quandam communem in propositione descriptam*.'"

"It cannot be denied, that there is a considerable degree of obscurity in this definition, notwithstanding of which it is certain, that every proposition to which it applies must contain a problematical part, viz. '*in qua proponitur demonstrare rem aliquam, vel plures datas esse*,' and also a theoretical part, which contains the property, or *communis affectio*, affirmed of certain things which have been previously described."

"It is also evident, that the subject of every such proposition is the relation between magnitudes of three different kinds; determinate magnitudes which are given; determinate magnitudes which are to be found; and indeterminate magnitudes which, though unlimited in number, are connected by the others by some common property. Now, these are exactly the conditions contained in the definitions that have been given here."

"To confirm the truth of this theory of the origin of porisms, or at least the justness of the notions founded on it, I must add a quotation from an essay on the same subject, by a member of this society, the extent and correctness of whose views make every coincidence with his opinions peculiarly flattering. In a paper read several years ago before the Philosophical Society, Professor Dugald Stewart defined a porism to be '*A proposition affirming the possibility of finding one or more of the conditions of an indeterminate theorem*.' Where, by an indeterminate theorem, as he had previously explained it, is meant one which expresses a relation between certain quantities that are indeterminate, both in magnitude and in number. The near agreement of this with the definition and explanations which have been given above, is too obvious to require to be pointed out; and I have only to observe, that it was not long after the publication of Simson's posthumous works, when, being both of us occupied in speculations concerning porisms, we were led separately to the conclusions which I have now stated."

For more on this subject, see Hutton's Mathematical Dictionary, article PORISM; also a very ingenious paper on Porisms by Henry Brougham, esq. in the Philosophical Transactions for 1798, or New Abridgment, vol. xviii. pa. 345—355.

PORISTIC METHOD. (ΠΟΡΙΣΤΙΚΗ.) In mathematics, is that which determines when, by what means, and how many different ways, a problem may be resolved,

PORK. *s.* (*porc*, Fr. *porcus*, Latin.) The flesh of swine killed for the purposes of food. If it have been pickled it is then called bacon.

PORKER. *s.* (from *pork*.) A hog; a pig (*Pope*).

PORKEATER. *s.* (*pork* and *eater*.) One who feeds on pork (*Shakspeare*).

PORKET. *s.* (from *pork*.) A young hog (*Dryden*).

PORKLING. *s.* (from *pork*.) A young pig (*Tusser*).

PORLOCK, a town in Somersetshire, with a market on Thursday, and a trade in coal and lime. It is seated on a bay of the Bristol channel, surrounded by hills, 14 miles N. by W. of Dulverton, and 170 W. of London.

POROSITY. *s.* (from *porous*.) Quality of having pores (*Bacon*).

POROUS. *a.* (*poreux*, French; from *pore*.) Having small spiracles or passages (*Milton*).

POROUSNESS. *s.* (from *porous*.) The quality of having pores; the porous part (*Digby*).

PORPHYRIUS, a famous Platonic philosopher, was born at Tyre in 233, in the reign of Alexander Severus. He was the disciple of Longinus, and became the ornament of his school at Athens; from thence he went to Rome, and attended Plotinus, with whom he lived six years. After Plotinus's death he taught philosophy at Rome with great applause, and became well skilled in polite literature, geography, astronomy, and music. He lived till the end of the third century, and died in the reign of Dioclesian. There are still extant his book on the Categories of Aristotle; a Treatise on Abstinence from Flesh; and several other pieces in Greek. He also composed a large treatise against the Christian religion, which is lost. That work was answered by Methodias, bishop of Tyre, and also by Eusebius, Apollinarius, St. Augustin, St. Jerome, St. Cyril, and Theodoret. The emperor Theodosius the Great caused Porphyry's book to be burned in 338. Those of his works that are still extant were printed at Cambridge in 1655, 8vo. with a Latin version.

"Porphyry," says Dr. Enfield, "was, it must be owned, a writer of deep erudition, and had his judgment and integrity bene equal to his learning, he would have deserved a distinguished place among the ancients. But neither the splendour of his diction, nor the variety of his reading, can atone for the credulity or the dishonesty which filled the narrative parts of his works with so many extravagant tales, or interest the judicious reader in the abstruse subtleties and mystical flights of his philosophical writings."

PORPHYRIUS. Porphyry. In mineralogy, a genus of the class earths, order aggregate. Consisting of distinct crystals of another genus imbedded in a compact hardened paste; massive, varying extremely in age, duration, hardness, and colour. This is a very extensive

tribe of earths, or rather of primitive rocks, and consists of not less than sixty-six different species, as enumerated by different mineralogists. They may be divided by the variety of substances constituting their base into the following sections.

A. Talcose: comprising three species; found in the valley Tellina, or in the Grisons; dullish green, sea-green, or silvery.

B. With a serpentine base: comprising eight species; as intermixed with quartz, garnets, mica, asbestos, iron, or feldspar. Found in the mountains of Tuscany, the Hercynian and Siberian mountains, in Hungary, Saxony, and the neighbourhood of Geneva, of various colours and hardness. Of these, one of the most useful is P. granitone, found in the mountains of Tuscany; green, with imbedded prisms of white feldspar; and sometimes a little silvery-green mica, frequently cut into mill-stones and grindstones.

C. With a base of amarus: comprising four species, as intermixed with feldspar, hornblend, mica, schorl, or garnets; all of which are found in the Swiss mountains.

D. With a calcareous base: comprising three species, as intermixed with quartz, mica, or schorl; found in Germany, Austria, or Tuscany.

E. With an argillaceous base. Seven species; as intermixed with feldspar, garnets, quartz, alumina, mica, schorl, asbestos, or chlorogranites, and often with many of these materials together. One of the most celebrated of these species is P. colarius, the clay porphyry of Thomson, the zechstein, coitenstein, mergelstein of the German oryctologists, composed of alumina and crystals of quartz, found on the banks of the Rhine, in Saxony, and various other places; with sometimes a few particles of feldspar mixed with it, which mouldering away, leaves it full of hollows.

F. With a basaltic base. Thirteen species; as imbedding trap, feldspar, schorl, quartz, hornblend, mica, wacke, calcareous spar, garnets or olivine, or various of these matters intermixed. Found in our own country, Sweden, Saxony, Bohemia, Fulda, and in the neighbourhood of Vesuvius. Of these, two species appear to have been employed by the sculptors of ancient Rome, and are now often met with among its ancient monuments: P. basalticus, consisting of basalt and feldspar, with sometimes a few particles of quartz and mica intermixed; and P. pedicularis, consisting of basalt and crystals of granatine schorl, with frequently a small mixture of hornblend, the crystals of schorl being sometimes so minute as scarcely to exceed the magnitude of the point of a needle. This division also may embrace P. anglia, turulite, or rowley-

rag, which nevertheless rather belongs to basaltes.

G. With the base of lava. Five species, as imbedding hornblend, granatine schorl, six-sided prisms of genuine schorl, mica or feldspar: Found chiefly around Vesuvius, but more or less in most volcanic countries, sometimes blending crystals of actinote, or garnet, with the other materials.

H. With the base of pitch. One species, P. piceus, pitchstone porphyry, imbedding feldspar and quartz. Found near Misena, in Saxony, forming entire mountains alternately with mountains of clay-porphry, in horizontal strata: colour black, green, brown, or red.

I. With a base of chert or hornstone. Eleven species, imbedding feldspar with a slaty or splintery texture, quartz, garnets, hornblend, mica, schorl, baryt, spar, or actinote. Found chiefly in Italy, Hungary, Bohemia, Saxony, Lusace, Switzerland, or the Tyrolese mountains. The two most worthy of notice are P. schistosus, and P. nothus; each consisting of hornstone and feldspar, the former with a slaty, the latter with a splintery texture: the first denominated horn-porphry, horn-schiefer, porphyrschiefer, found common in Bohemia, Lusace, and the bishopric of Fulda, rarely containing ores of metal; colour grey or black, and often marked with arborescent ramifications: in Italy approaching to a basalt, and melting in the fire to a yellowish glass, but not so easily as basalt; the chest of feldspar mixed in various proportions, to which is sometimes added hornblend, rarely garnets, mica, or spar, very rarely veins of marble.

The second is denominated hornstone-porphry; hornquartz-porphry; hornortiger trapp: it has sometimes a little hornblend, and sometimes a little jasper mixed with it. Found in various proportions of constituent parts and colours in the mountains of Lower Italy, Hungary, Bohemia, Saxony, Carinthia, the boundaries of the Lower Rhine, and Denmark.

K. With a base of jasper. Nine species, of which the chief is P. genuinus. Jasper porphyry. Found in Egypt, Arabia, Greece, Italy, south of France, Siberia, and most parts of Europe. Sometimes detached, sometimes forming rocks, mountains, or their principal parts; opaque, of a texture more commonly approaching to the conchoidal than the slaty, hard and admitting a fine polish, breaking into indeterminate fragments, easily melting in the fire; generally of a common form, rarely in prisms, and then always mixed with other bodies, as hornblend, mica, schorl, or quartz; infinitely varying in the colour, form, distribution, and mixture of its constituent parts; the feldspar generally white or reddish, immersed in jasper

in the form of dots, spots, stripes, or prisms, and sometimes moulder away and leaving cavities; the jasper red, brown, black, or green, rarely dull grey, or of two colours, as, black and green, red and orange. It was used by the ancients in the structure of columns, temples, and edifices of the highest orders.

Another species well worth noticing under this division is P. achates: agate; hard agate; jasper agate; striped jasper. Composed of jasper, quartz, rock-crystal, amethyst, chalcedony, cornelian and onyx, hornstone and flint, variously combined together; sometimes disposed in alternate, straight, rarely undulate bands, differing in colour: sometimes consisting of fragments angularly crustose; or with figures resembling landscapes; or in painted annulations of different colours; or with figures resembling moss; or resembling stellar dots.

Found in infinite varieties of proportion and distribution of parts, tinge of colours, hardness and lustre in Britain, Ceylon, and most parts of Europe, sometimes detached, sometimes imbedded in clay, rarely in veins or a stalactitical form, and is used for rings, ornaments, and decorations of nobler edifices.

PORPOISE, in mastiology. See DELPHINUS.

PORRA'CEOUS. *a.* (*porraceus*, Latin; *porrace*, French.) Greenish (*Wiseman*).

PORRE'CTION. *s.* (*porrectio*, Lat.) The act of reaching forth.

PO'RRET. *s.* (*porrum*, Latin.) A scallion.

PO'RRIDGE. *s.* (more properly *porrage*; *porrata*, low Latin, from *porrum*, a leek.) Food made by boiling meat in water; broth.

PO'RRIDGEPOT. *s.* (*porridge* and *pot*.) The pot in which meat is boiled for a family.

PORRIGO. (*porrigendo*, from its spreading abroad.) A disease very common among children, in which the skin of the hairy part of the head becomes dry and callous, and comes off like bran upon combing the head.

PO'RRINGER. *s.* (from *porridge*.) 1. A vessel in which broth is eaten (*Bacon*). 2. It seems in *Shakspeare's* time to have been a word of contempt for a headress.

PORRUM. The common leek. *Allium porrum* of Linnéus. Every part of this plant, but more particularly the root, abounds with a peculiar odour. The expressed juice possesses diuretic qualities, and is given in the cure of dropsical diseases, and calculous complaints.

PORSELOU, a rich and commercial town of the kingdom of Siam. It is surrounded with fourteen bastions, and situate on a large river, 300 miles N. of its mouth in the gulf of Siam. Lon. 100. 2 E. Lat. 17. 48 N.

PORSON (Richard), a very eminent Greek scholar, was born at East Ruston, in Norfolk, on Christmas-day, 1759. Every thing about this most eminent scholar, and particularly the circumstances which laid the foundation of that most inestimable memory, by which he was enabled to store his mind with all the

P O R S O N.

riches of literature, ancient and modern, will become truly interesting to the world. He owed the blessing to the care and judgment of his father, Mr. Huggin Porson, who was parish-clerk of East Ruston, and who, though in humble life, and without the advantages himself of early education, laid the basis of his son's unparalleled acquirements. From the earliest dawn of intellect Mr. Porson began the task of fixing the attention of his children, three sons and a daughter; and he had taught Richard, his eldest son, all the common rules of arithmetic, without the use of a book or slate, pen or pencil, up to the cube root, before he was nine years of age. The memory was thus incessantly exercised; and by this early habit of working a question in arithmetic by the mind only, he acquired such a talent of close and intense thinking, and such a power of arranging every operation that occupied his thought, as in process of time to render the most difficult problems, which to other men required the assistance of written figures, easy to the retentive faculties of his memory. He was initiated in letters by a process equally efficacious. His father taught him to read and write at one and the same time. He drew the form of the letter either with chalk on a board, or with the finger in sand; and Richard was made at once to understand and imitate the impression. As soon as he could speak he could trace the letters; and this exercise delighting his fancy, an ardour of imitating whatever was put before him was excited to such a degree, that the walls of the house were covered with characters which attracted notice from their neatness and fidelity of delineation.

At nine years of age, he and his youngest brother, Thomas, were sent to the village-school, kept by a Mr. Summers. He professed nothing beyond English, writing, and arithmetic, with the rudiments of Latin: he was a good accountant and an excellent writing-master. He perfected the professor in that delightful talent of writing, in which he so peculiarly excelled; but which we are doubtful whether it was to be considered as an advantage or a detriment to him in his progress through life. It has been the means, however, of enriching his library with annotations, in a text the most beautiful, and with such perfect imitation of the original manuscript or printing, as to embellish every work which his erudition enabled him to elucidate. He continued under Mr. Summers for three years; and every evening during that time he had to repeat by heart to his father the lessons and tasks of the day; and this not in a loose or desultory manner, but in the rigorous order in which whatever he had been occupied about had been done; and thus again the process of recollection was cherished and strengthened, so as to become a quality of his mind. It was impossible that such a youth should remain unnoticed, even in a place so thinly peopled, and so obscure as the parish of East Ruston. The reverend Mr. Hewitt heard of his extraor-

dinary propensities to study, his gift of attention to whatever was taught him, and the wonderful fidelity with which he retained whatever he had acquired. He took him and his brother Thomas under his care, and instructed them in the classics. The progress of both was great, but that of Richard was most extraordinary. It became the topic of astonishment beyond the district, and when he had reached his fourteenth year, had engaged the notice of all the gentlemen in the vicinity. Among others, he was mentioned as a prodigy to an opulent and liberal man, the late Mr. Norris, who after having put the youth under an examination of the severest kind, and from which an ordinary boy would have shrunk dismayed, sent him to Eton. This happened in the month of August, 1774, when he was in his 15th year; and in that great seminary, he, almost from the commencement of his career, displayed such a superiority of intellect, such facility of acquirement, such quickness of perception, and such a talent of bringing forward to his purpose all that he had ever read, that the upper boys took him into their society, and promoted the cultivation of his mind by their lessons, as well, probably, as by imposing upon him the performance of their own exercises. He was courted by them as the never-failing resource in every difficulty; and in all the playful excursions of the imagination, in their frolics as well as in their serious tasks, Porson was the constant adviser and support.

The death of Mr. Norris was the source of severe mortification to him; for though by the kindness of some eminent and liberal persons he was continued at Eton, he felt the loss he had sustained in the most poignant degree. But we cannot now do more than trace the dates of his progress to the professor's chair. He was entered of Trinity college towards the end of 1777, and his character having gone before him to the university, he was from the first regarded as a youth whose extraordinary endowments would keep up and extend the reputation of the unrivalled society into which he had entered. Nor did he disappoint the hopes that had been formed of him. In every branch of study to which he applied himself, his course was so rapid as to astonish every competent observer. By accidents he was drawn first to read in mathematics, in which, from his early exercises, he was so eminently calculated to shine, but from which he drew no benefit; and then by the prospect of a scholarship, which, however, did not become vacant till long after, he sat down to the classics. In this pursuit he soon acquired undisputed pre-eminence. He got the medal of course, and was elected a fellow in 1781. In 1785 he took his degree of master of arts; but long before the period had elapsed when he must either enter into holy orders or surrender his fellowship, he had (after the most grave and deliberate investigation, to which he had brought all that acute gift of examination that has been made so perceptible in his letters to Mr. archdeacon Travis) made up his mind on the sub-

ject of subscription. So early as 1788, he had determined to surrender his fellowship, though with an enfeebled constitution he had nothing to depend upon but acquisitions that are very unprofitable to their owner. A lay-fellowship, to be sure, might have secured his services to the cause of letters; but the disingenuous conduct of an individual withheld from him that resource. In 1791 his fellowship ceased, and he was thrown upon the world without a profession, his feelings wounded by the mortifications he had suffered, and with a constitution little qualified to encounter the bustle of the world. Some private friends, however, stepped in, and soon after he was elected Greek professor at Cambridge by an unanimous vote of the seven electors. The distinction of this appointment was grateful to him. The salary is but 40*l.* a year. It was his earnest wish, however, to have made it an active and efficient office, and it was his determination to give an annual course of lectures in the college, if rooms had been assigned him for the purpose. These lectures, as he designed, and had in truth made preparations for them, would have been invaluable; for he would have found occasion to elucidate the languages in general, and to have displayed their relations, their differences, their near and remote connections, their changes, their structure, their principles of etymology, and their causes of corruption. If any one man was qualified for this gigantic task, it was Mr. professor Porson; and if his wishes had not been counteracted, we know that he would have undertaken the labour.

From this time, instead of lectures, he turned his thoughts to publication. His letters to Mr. archdeacon Travis, as has been truly said, put the controversy on the disputed text to rest; and indeed it was the peculiar felicity of his mind, that whatever he undertook to elucidate he fixed for ever in the light.

In 1795 he married Mrs. Lunan, the sister of Mr. Perry, editor of the *Morning Chronicle*, but who sunk under a decline in 1797, and from that time the professor himself was so incessantly afflicted with a spasmodic asthma, as to interrupt him in every study to which he applied himself. Whether his sedentary habits served to bring it on we know not, but certainly very few men had accustomed themselves to such patient and continued toil. He had undertaken to make out and copy the almost obliterated manuscript of the invaluable lexicon of Photius, which he had borrowed from the library of Trinity college. And this he had with unparalleled difficulty just completed, when the beautiful copy which had cost him ten months of incessant toil, was burnt in the house of Mr. Perry at Merton. The original being an unique, entrusted to him by his college, he carried with him wherever he went; and he was fortunately absent from Merton on the morning of the fire. Unruffled by the loss, he sat down without a murmur, and made a second copy as beautiful as the first. It is extant in his library, and is quite ready for the press. Of the plays of Euripides, which he

published, the learned world has pronounced its judgment. Besides these he has left an *Orestes* quite ready for the press.

On the establishment of the London Institution, the managers manifested their own discernment and love of letters by selecting him to be their principal librarian, an appointment for which he was peculiarly qualified, and by which, if time and health had been allowed him, he would have made their library truly valuable. But he was seized with an intermittent fever early in September, 1808, for which, as he had an unfortunate objection to medical advice, he resorted to his usual remedy of abstinence; but on Monday the 19th, he suffered an apoplectic stroke, from which he recovered only to endure a second attack the next day. He languished to the Sunday night, and expired without a struggle, in the 49th year of his age.

The principal qualities in this great man's mind were his extraordinary acuteness of discernment and solidity of judgment; and these, added to his intense application and stupendous memory, made him, what the world perhaps never saw before, a complete critic, in the most honourable and extended sense of that appellation. His reading was of course immense; he was an excellent French scholar; but in his native language, in the Latin, and in the Greek, he was most familiarly and profoundly versed. He had indeed applied the knowledge he had gained of the origin and structure of language in general to all these dialects (if we may so express ourselves) of the universal language; and, had not his eminence in classical literature, by its uncommon lustre, obscured other attainments, he would doubtless have been considered as one of the first English scholars. In Greek, however, we have no hesitation in pronouncing him the very first, not merely of his own age, but of every other. He is surely entitled to this honourable distinction, when we consider that he possessed at once, each in its highest degree of excellence, all the qualities for which any single scholar has hitherto been eminent. In him were conspicuous boundless extent of reading; a most exact and well ordered memory; unwearied patience in unravelling the sense of an author, and exploring the perplexities of a manuscript; perspicacity in discovering the corruptions of a text; and acuteness, almost intuitive, in restoring the true reading. All this, be it observed, was tempered with a judgment which preserved him invariably from the rocks against which even the greatest of his critical predecessors have at some time or other split; we mean precipitation in determining that to be unsound, which after all had no defect; and rashness in applying remedies which only served to increase the disease.

PORT, a commodious place situated on the sea-coast, or at the mouth of a river, screened from the wind and the enterprizes of an enemy, with depth of water sufficient for ships of burden, and where vessels lie by to load and unload.

Ports are either natural or artificial; the

natural are those formed by Providence, and the artificial such as are formed with moles running into the sea. The city of Constantinople is called the Port, from its having one of the finest ports in Europe. All the ports and havens in England are within the jurisdiction of the county; and the court of admiralty cannot hold jurisdiction of any thing done in them. 30 Henry VI.

PORT HOLES, in a ship, are the holes in the sides of the vessel through which are put the muzzles of the great guns. These are shut up in storms to prevent the water from driving through them. The English, Dutch, and French ships, have the valves or casements fastened at the top of the port holes, and the Spanish vessels aside of them.

PORT, signifies also a gate. And is often used to denote the carriage; air; mien; manner; bearing.

PORT, is also a strong wine brought from Port-a-port, and also called Porto and Oporto.

PORT OF THE VOICE, in music, the faculty or habit of making the shakes, passages, and diminutions, in which the beauty of a song or piece of music consists.

To PORT. v. a. (porto, Lat. porter, Fr.) To carry in form.

PORT-CRAYON, a pencil-case, which is usually four or five inches long, and contrived so that the pencil may slide up and down. Its inside is round, and its outside is sometimes filed into eight sides or faces, on which are drawn the sector-lines; sometimes it is made round both without-side and within, and has its length divided into inches, and parts of inches.

PORT-FIRE, a composition for setting fire to powder, &c. Port-fires are frequently used by the artillery in preference to matches; and they are distinguished into wet and dry port-fires. The composition of the former is saltpetre four, sulphur one, and mealed powder four. When these materials are thoroughly mixed and sifted, the whole is to be moistened with a little linseed oil, and rubbed between the hands till all the oil is imbibed by the composition. The preparation for dry port-fires is saltpetre four, sulphur one, mealed powder two, and antimony one. These compositions are driven into small paper cases, to be used whenever necessary. See **MATCH**.

PORT DESIRE, a harbour on the E. coast of Patagonia, where ships sometimes touch in their passage to the Pacific ocean. Lon. 67. 56 W. Lat. 47. 50 S.

PORT EGMONT, one of the finest harbours in the world, on the N.W. coast of Falkland Islands, discovered by commodore Byron in 1765. The whole navy of England might ride here in perfect security from all winds; and every thing for the refreshment of ships is to be obtained here in abundance. Lon. 55. 0 W. Lat. 51. 27 S.

PORT JACKSON, a large bay on the coast of New South Wales, three leagues and a half N. of Cape Banks. The capes that form its entrance are high, rugged, and perpendicular

cliffs. On proceeding within, in 1788, governor Philip discovered a large branch extending to the south, and found himself perfectly landlocked, with a good depth of water; and finding also, that the country was greatly superior to that round Botany Bay, he determined to fix the colony of convicts here, which had been originally intended for Botany Bay. The name of Port Jackson had been given to it by captain Cook, as he observed it in sailing along the coast. Lon. 151. 28 E. Lat. 33. 50 S.

PORT L'ORIENT. See **ORIENT**.

PORT LOUIS, a strong town of France, in the department of Morbihan, with a citadel, and a good harbour. It is a station for part of the French navy, and the East India company's ships; and is seated at the mouth of the Blanet, 27 miles W. of Vannes. Lon. 3. 18 W. Lat. 47. 40 N.

PORT LOUIS, a French fortress, on the S.W. coast of Hispaniola, demolished by admiral Knowles in 1747, but since rebuilt. Lon. 73. 16 W. Lat. 18. 18 N.

PORT LOUIS, a town and harbour of the Isle of France, in the Indian Ocean, strongly fortified. Lon. 57. 28 E. Lat. 20. 9 S.

PORT MAHON. See **MINORCA**.

PORT PAIX, a town on the north coast of St. Domingo, in the West Indies, with a good harbour. Lon. 72. 55 W. Lat. 19. 58 N.

PORT PATRICK, a seaport in Wigtonshire, confined by the sea on one side, and on the other by over-hanging rocks and hills. It is noted for its ferry to Donaghadee in Ireland, from which it is only 20 miles distant; and a packet-boat sails from hence for that place every day. The harbour is good; and has one of the finest quays in Great Britain, with a reflecting lighthouse. It is 107 miles S.W. of Edinburgh, and 487 N.W. of London.

PORT ROSEWAY. See **SHELBOURNE**.

PORT ROYAL, a seaport of Jamaica, once one of the finest towns in America, abounding in riches and trade. In 1692, it was destroyed by an earthquake, in 1702 by a fire, in 1722 by an inundation of the sea, and in 1744 it suffered greatly by a hurricane. It still consists of three handsome streets, built on a small neck of land which juts out several miles into the sea, and is guarded by a strong fort. The harbour is one of the best in the world, and 1000 ships may ride therein, secure from every wind. It is six miles E. of Spanish Town, and as much by water S.E. of Kingston. Lon. 76. 45 W. Lat. 18. 0 N.

PORT ROYAL, a town and fort of the island of Martinico, 21 miles S.E. of St. Pierre. Lon. 61. 9 W. Lat. 14. 3 N.

PORT ROYAL, a town of the United States, in Virginia, on the river Rappahannoc.

PORT ROYAL, an island on the coast of South Carolina, the space between which and the neighbouring continent forms one of the most commodious harbours in those parts. It is 15 miles in length, and the town on the N. shore, called Beaufort, is 100 miles S.W. of

Charleston. Lon. 80. 10 W. Lat. 31. 40 N.

PORT ROYAL, in Nova Scotia. See AN-NAPOLIS.

PORT ST. ANN. See KILLOUGH.

PORT ST. JULIAN, a harbour on the coast of Patagonia, where ships usually touch that are bound for the Pacific Ocean. Lon. 68. 44 W. Lat. 49. 10 S.

PORT ST. MARY, a seaport of Spain, in Andalusia. The English made a descent here in 1702, with a design to besiege Cadiz, but without success. It is 10 miles N.E. of Cadiz. Lon. 6. 0 W. Lat. 35. 37 N.

PORT SANDWICH, a harbour in the island of Mallicolo, in the S. Pacific Ocean. Lon. 167. 53 E. Lat. 16. 25 S.

PORT VENDRE, a seaport of France, in the department of the Eastern Pyrenees and late province of Rousillon. It was taken by the Spaniards in 1793, but retaken the next year. It is 25 miles S. by E. of Perpignan.

PORTA. (*porta*, a *portando*, because through it the blood is carried to the liver.) That part of the liver where its vessels enter.

PORTÆ VENA. See VENA PORTÆ.

PORTA (Joseph), of Castel Nuovo, acquired celebrity by his pieces in oil and in fresco. He wrote also some mathematical treatises, and died at Venice 1585, aged 50.

PORTA (John Baptist), a Neapolitan, eminent for his learning. As he admitted a society of learned friends into his house, he was accused of magical incantations, and exposed to the censures of Rome. He died 1515, aged 70. He invented the camera obscura, improved afterwards by Gravesande, and formed the plan of an encyclopedia. He wrote a Latin treatise on natural magic, 8vo.; another on physiognomy, mixed with astrology, &c.; *de occultis literarum notis*; *physiognomica*, folio, &c.

PORTA (Simon), or PORTIUS, a Neapolitan, distinguished by his learning, and professor of philosophy at Pisa. He died at Naples 1554, aged 57. He is author of treatises *de mente humanâ—de voluptate et dolore—de coloribus oculorum*, 4to.—*de rerum naturalium principiis libri duo—opus physiologicum*, 4to, &c.

PORTABLE. *a.* (*portabilis*, Latin.) 1. Manageable by the hand. 2. Such as may be born along with one (*South*). 3. Such as is transported or carried from one place to another (*Locke*). 4. Sufferable; supportable.

PORTABLENESS. *s.* (from *portable*.) The quality of being portable.

PORTADOWN, a town of Ireland, in the county of Armagh, with an extensive linen manufacture. It is situate on the river Bann, nine miles N.E. of Armagh, and 16 N. of Newry.

PORTAGE. *s.* (*portage*, French.) 1. The price of carriage (*Fell*). 2. (from *port*.) Porthole (*Shakspeare*).

PORTAL. *s.* (*portail*, French.) A gate; the arch under which the gate opens (*Sandys*).

PORTALEGRE, a strong town of Portugal, in Alentejo, with a bishop's see. It is seated at the foot of a high mountain, in a pleasant country, 30 miles N.W. of Elvas, and 90 N. E. of Lisbon.

PORTANCE. *s.* (from *porter*, Fr.) Airy mien; port; demeanour (*Spenser*).

PORTASS. *s.* (sometimes called *portuis*.) A breviary; a prayer-book (*Camden*).

PORTARLINGTON, a borough of Ireland, partly in King's and partly in Queen's county. It is seated on the river Barrow, 31 miles N. of Kilkenny, and 36 S.W. of Dublin.

PORTCULLICE, in fortification, is an assemblage of several large pieces of wood, joined across one another like a harrow, and each pointed with iron at the bottom. They are sometimes hung over the gateway of old fortified towns, ready to let down in case of surprise, when the gates could not be shut.

To PORTE'ND. *v. a.* (*portendo*, Lat.) To foretoken; to foreshow as omens (*Roscommon*).

PORTE'NSION. *s.* (from *portend*.) The act of foretokening: not in use (*Brown*).

PORTE'NT *s.* (*portentum*, Latin.) Omen of ill; prodigy foretokening misery (*Dryden*).

PORTE'NTOUS. *a.* (*portentosus*, Latin.) 1. Foretokening ill; ominous (*Shakspeare*). 2. Monstrous; prodigious; wonderful (*Roscommon*).

PORTER. *s.* (*portier*, French; from *porta*, Latin, a gate.) 1. One that has the charge of the gate (*Arbutnot*). 2. One who waits at the door to receive messages (*Pope*). 3. (*porteur*, French.) One who carries burdens for hire (*Howel*).

PORTER. A malt liquor of a deep brown colour and a peculiar flavour, which it derives from the malt used in brewing, it being highly dried in the malt-kilns. This, at least, was the composition of porter until lately, when it has been found that the same colour and flavour may be communicated to liquor brewed from a mixture of brown and pale malt, by the addition of certain colouring matters, which being obtained from burning the same substance that causes the brown colour of the highly dried malt, produces a similar liquor at a far less expence of materials than when brown malt alone is used; because the pale malt yields a far greater proportion of saccharine matter than the brown, in which a share of the saccharum is burnt up in the kiln only for the purpose of producing a colour and flavour which may so easily be communicated to the beer of pale malt by a small quantity of burnt sugar.

The art of brewing porter is referable to the same general principles as any other beer. (See BREWING.) What we chiefly intend to explain in this article is the admirable system of management under which the process is conducted in the great porter breweries in London, some of which are on such an ex-

PORTER.

tensive scale as to brew 100,000 barrels annually in one house.

The process of brewing porter as generally practised with but trifling variations in these works is as follows. The different kinds of malt made use of are pale, brown, and amber, which is a medium between the two. Some brewers use equal quantities of the three; others equal proportions of pale and brown; others use amber malt alone; and some pale malt with one-third of brown. These varieties give to their porter the different flavours for which they are distinguished by the connoisseurs in this liquor.

The malt being coarsely ground, or in some breweries bruised between iron rollers, is deposited in the mash tun, into which water is admitted, heated to 150 degrees of Fahrenheit (when the malt is compounded of the three kinds) for the first mashing; and in quantity at the rate of two barrels per quarter of malt. It is next mashed and mixed up by the mashing engine about three-quarters of an hour; then it stands to extract the saccharum of the malt for an hour, at the end of which the wort, called the first wort, is run off into the under back. In a large mash tun it will take half an hour to run off, and is immediately pumped up into the copper to be boiled. At about an hour and three-quarters, or two hours, from the commencement, the water for the second mash is admitted into the mash tun at a heat of 160 degrees, but only one barrel to the quarter of malt, because the malt is already wetted from the first liquor. It is mashed by the engine for half an hour, and stands an hour; after which it is run off. During this time the first wort has been boiling in the copper, where the hops are put to it, usually at the rate of six or seven pounds to the quarter of malt, which makes three barrels and a half of porter; but this quantity is increased or diminished as the liquor is intended for keeping, or for a quick consumption. After boiling the proper time (the length of which is much disputed, and greatly varied by different brewers) the wort is run off into the coolers. The third mash is made at about two hours and a half after beginning the second mash; it is heated to 180 degrees, and at the rate of one barrel one firkin per quarter: it is mashed half an hour, and stands one hour, as the other mashes; before it is run off. A fourth mash is sometimes made, but it is only taken at a blood heat and sufficient quantity to cover the malt, upon which it stands two hours; it is used to make sour beer for the finings, as will be hereafter explained, though some brewers boil it again the next morning for the first mash instead of fresh water. This practice, however, is not a good one, because the wort by standing all night frequently becomes *foxed*; a term used by the brewers to denote a premature fermentation of the wort before the gross mucilaginous parts of the extract are coagulated by the process of boiling. The first wort being richer than the others soon contracts the fox, particularly in hot weather, if it is left in the

under back, and therefore it is pumped up into the copper as soon as the water which was heated in the copper for the second mash can be run out into the mash tun. The weaker worts may stand much longer without danger of foxing; and therefore the fourth wort when taken may in cold weather stand all night, and be good the next morning to use instead of fresh water; in which case a considerable saving of malt will be made, or the liquor be stronger: but if, on the other hand, it becomes tainted, a whole brewing of beer may be spoiled by it. On this account the most established brewers rather choose to lose the advantage than take the risk, and therefore make only three mashes.

The boiling of the wort coagulates the mucilage suspended in the liquor, and separates it into distinct fecula, which, when it is run into the coolers, deposit themselves in considerable quantities. By this means it is freed from the superabundant portion of gross fermentable matter, which would otherwise occasion the beer to proceed so rapidly through the process of fermentation, that those gross parts would come to the acetous, and even the putrefactive, fermentation before the other parts of the beer had advanced sufficiently in the vinous fermentation to give the liquor its proper strength. The addition of the hops which is made in the boiling also tends to the same effect, of retarding the fermentative disposition; and for this reason the proportion of hops must be regulated by the time the beer is intended to be kept. If it is intended for exportation it must have a large quantity of hops; and then it will be kept long enough to fine itself, at least in a great degree, by the gradual subsidence of the minute fecula suspended in it. But the porter brewed for the supply of London is kept a very short time, and therefore has a small share of hops; and as it would not have time to become fine, it is fined by a peculiar process on purpose.

The different worts after boiling are spread out thin in the coolers, and their temperature brought down to between 60 and 70 degrees, at which all the three worts are mixed together in a great vessel called the guile tun or square, where yeast being put to it the liquor is fermented. The temperature at which the wort is set to working in the square, and the heat at which the several mashes are made, have greater influence than any other circumstances upon the quality of the beer. The greater the working heat is, the more rapidly the fermentation proceeds: therefore in summer, when the natural heat of the air is such that the working will advance perhaps more rapidly than the brewer wishes, he counteracts this by cooling the wort down as low as possible: on the other hand, in cold weather the fermentation must be encouraged by commencing it at a greater temperature; in general it may be stated to be between 60 and 70 degrees, at the discretion of the brewer, and in some degree regulated by the kind of porter he wishes to produce, and the malt from which he has

extracted his wort. The fermentation is continued in the square as long as the head of yeast which floats upon it continues to increase in depth; but when the head shews signs of diminution the liquor is fit for cleansing. This is putting it into a great number of small casks, which, by dividing the beer into small quantities, lowers its temperature and tends to check the fermentation. The same end is also attained by causing the yeast to flow off as fast as it is produced, and keeping the casks always filled up as they diminish by working, to leave no room for a head of yeast to gather upon the surface of the beer. After the fermentation is concluded the beer is put into immense casks called store vats, where it is kept till wanted for sale. By keeping it begins to clear itself, and grow fine; but it is seldom kept long enough to become perfectly so. It is when wanted drawn off from the store vats into casks, and then sent away; and the consumer puts into the cask a small quantity of *fining*, sent out with the porter by the brewer, who calls it *in the rough* when his liquor requires fining.

The finings are made of isinglass dissolved in sour beer brewed from the wort of the fourth mash, or sour beer obtained from the waste of any of the processes. A small quantity of this fining beer being put into the cask precipitates the minute scum, and soon renders the liquor quite fine. The flavour of the draught porter in London is almost universally obtained by compounding two kinds, the due admixture of which is palatable, though neither are good alone. One is mild, and the other stale porter; the former is that which has been lately brewed, and has rather a bitter mawkish flavour; the latter has been kept longer, and is in some degree acid. This mixture the publican adapts to the taste of his several customers; he effects the proportion of mixture very readily by means of the BEER PUMPS, described under that article (see pl. 24). These will be found to have four pumps, but only three spouts, because two of the pumps throw out at the same spout. One of these two pumps draws mild, and the other the stale porter; and the publican, by dextrously changing his hold to the next handle works, either pump, and draws both kinds of beer at the same spout; and an indifferent observer supposes that since it all comes from one spout it is entire butt beer, as the publican professes over his door, and which vulgar prejudice has decided to be the only good porter, though the difference is not easily distinguished.

A walk through an extensive London porter brewery, as Mr. Whitbread's, Meux's, Barclay's, or many others, is very interesting, by reason of the very extensive scale on which their processes are conducted, by the aid of the steam engine, which is applied to perform all the laborious operations without exertion of the workmen, who are very few in number considering the magnitude of the works.

Plate 140 contains an elevation of a porter brewery, shewing all the vessels and machinery at one view. This elevation is in some

measure imaginary, as few works have their vessels so arranged as to be all seen at once; being often situated one behind the other as the local convenience of the building demands. AA represents the walls supporting the copper B, and containing the fire-place at C with the fire grate, and chimney *r*. Above the copper is a vessel D, called the copper-pan, in which the liquor is heated previously to being let down into the copper. E is the mash-tun containing the mashing machine, of which we have given a detail in plate 141. Over this is a bin F to contain the malt, after it has been ground in the millstones, *aa*. These are turned by wheel-work from the steam-engine, of which *b* is the fly-wheel: this, by bevelled cog-wheels on its axis, turns a vertical shaft *c*, upon which are other bevelled wheels giving motion to the rest of the machinery. The beam of the steam-engine works a pump down in the well G, by which cold water is raised up to a large cistern H, supported on the walls of the engine house. From this cistern a pipe *d* proceeds to the copper where the water is heated, and is then let out at the cock *e* into the mash-tun, previously filled with ground malt, let down from the bin F. When sufficiently mashed, the wort is let down into a vessel I beneath the mash-tun, called the underback, from which it is drawn by the pumps K, and conducted by the pipe *ff* up to the copper-pan D. In this pan it derives considerable heat from the copper when any liquor is boiling beneath, as the steam rising from it cannot escape, because the copper is covered with a dome-head; it therefore ascends through the large-central pipe *g*, and turning down the inclined pipes *h, h*, bubbles out beneath the surface of the liquor contained in the pan D, and by this means communicates a very considerable heat to it, which, as well as what comes up through the dome of the copper, would otherwise be lost. When the water in the copper is let out into the mash-tun to make the second mash, the wort is let down from the copper-pan into the copper to be boiled; and the hops are put in at a door in one side of the dome covering the copper, the pan D being notched in on that side to give access to it. The hops are kept stirring all the time the boiling is continued, to prevent their burning to the bottom of the copper. It is done by a vertical spindle *s*, in the centre of the copper, which is put in motion by cog wheels at *t*, turned by hand, or sometimes by the engine. At the lower end of the spindle a cross bar *v* is fastened, and to this chains are linked, which drag round upon the bottom of the copper when the wheels are turned. This machine is called the *rouser*: it can be drawn up out of the way when the copper requires cleaning, by a chain *w* passing over pulleys, and drawn by proper rollers.

After boiling, the worts and hops together are run out at the cock *e*, and conducted by a spout into a large vessel called the jack-back (which being before the copper cannot be shewn in our late): it has a false bottom &

few inches above the real bottom, pierced with a great number of small holes to retain the hops, but allow the wort to run off, when it is drawn by the pumps K, and thrown up through pipes into any one of the coolers at L L. These latter are large shallow backs, where the liquor remains till cooled to the proper temperature, and is then let down into a large vessel M, called the *square*. In this yeast is put to it, and it is fermented for a certain time. The second wort passes through exactly the same vessels as the first, and when it comes to the copper to be boiled, the hops are drawn up in baskets from the jack-back (by a rope winding round the roller *i* turned by the engine), and put into the copper to be boiled again; and after this the second wort follows the first wort through the same kind of vessels, and is mixed with it in the square M. The malt is drawn up to the mill in sacks by the same or a similar roller, as *i*, and deposited in large bins (which cannot be seen in the plate), where it is kept till wanted, and is then brought to the mill *aa*.

After the beer has been fermented the proper time in the squares, it is run off with the yeast by proper pipes into a great number of small tuns at N, called the *rounds*. In these the fermentation is completed, the yeast running off as fast as it is produced through spouts *l*, into a large vessel O beneath. When the fermentation is concluded, the beer is drawn off and pumped by a pump similar to that at K (but farther from the engine) into very capacious tuns, usually situated in another building, and therefore omitted in the plate. They are indeed of enormous capacity, some containing as much as 5000 barrels, being 40 feet in diameter. In these it is kept till wanted for sale, when it is drawn off into small casks, and sent away from the brewery.

Plate 141 contains drawings of a mashing machine made by Mr. Cooper of Old-street, London. Fig. 1 is a perspective view of the mash-tun, with a part of its staves removed to expose the machine within it. Fig. 2 is a plan; fig. 3 an elevation; fig. 4 an end view of the machine; and fig. 5 is an end view of fig. 2. A is a vertical shaft, turned round by the engine. It has two bevelled cog-wheels upon it, at B and C, which turn two others upon horizontal shafts D and E. These are supported in a framing of cast iron, consisting of two pieces; one surrounding the vertical shaft, as shewn at X, in figs. 1 and 4, and the other marked F, is supported upon small wheels *aa*, figs. 2 and 5, which run upon the edge of the tun. These frames are united by the rods GG, fig. 2. The framing also supports a horizontal shaft H near the bottom of the tun. It has four wheels I upon it, and the uppershaft E has four others corresponding with it. From each of these wheels to its fellow an endless chain is extended, and upon the links of these, cross pieces K, called *rakes*, are fixed, having a number of pegs driven through them, as is shewn in figs. 1, 3, and 4. By the motion of the vertical axis the others are turned

round, and the chains revolve with their rakes, which descend through the malt to the bottom of the tun, and then rise up again; by this means agitating it most effectually. At the same time that this motion is going on, the whole machine revolves round in the tun, so as to constantly operate upon a fresh part of the materials. This motion is effected by an endless screw at *b*, in the frame F, figs. 2 and 5, which runs upon the edge of the tun. This endless screw has a pinion on its axis turned about by the wheel *d*, on the end of the horizontal shaft D. The thread or spiral of the screw is engaged with a ring of cogs fixed all round in the edge of the tun at LL; and by this means the whole machine is slowly advanced round the tun as the screw revolves. The wheel *d* has two rings of teeth upon it of different diameters, and both of these work in pinions on the axis of the screw, therefore turning them with different velocities. Now one or other of these pinions being locked in gear by the lever *e*, will cause the screw to revolve with a greater or less velocity, in proportion to the different sizes of the above-mentioned rings of cogs on the wheel *d*.—The mash-tun is filled up with a false bottom MM, leaving a space of one or two inches between it and the real bottom N. The false bottom is pierced with a great number of small holes, through which the wort percolates when drawn off, leaving the malt above lying on the false bottom.

The reader is now acquainted with the arrangement of the several vessels and the principal machinery employed in a brewery: the following is, with little variation, the routine of daily business. They begin very early in the morning, as one or two o'clock, to light the copper and steam-engine fires, the copper and the pan over it having been filled with water (called liquor) from the liquor-back the preceding evening, and the back filled up again by the liquor pump attached to the steam-engine; and at the same time the malt was let down from the bin into the mash-tun, during which time the space between the bin and the tun was enclosed with curtains, to prevent any loss of malt by the dust. When the liquor (water) is properly heated, the fire under the copper is damped by opening the fire door, and the liquor is run off at the cock *e* into the mash-tun. It is conducted by a pipe into the space between the true and false bottoms of the tun, and rises up through the malt lying upon the latter immediately or even before the first liquor quits the copper, that contained in the pan over the copper is let down (rather warmed by the heat rising from the copper) to supply its place, and prevent the bottom of the copper from burning, as it would do in a short time if left empty. The copper-pan is filled up again from the liquor-back, and the fire made up to heat this liquor to make the 2d mash. When the first liquor is run into the mash-tun, the mashing engine is put in motion by the engine to agitate and stir up the malt, that every part may be thoroughly mixed and subjected equal-

ly to the action of the water. This continues three-quarters of an hour, and then the machine is stopped, the mash stands still to extract for an hour, and the wort is then let down by a large cock in the bottom into the under-back beneath. It will take a long time to drain off from the malt; and by that time the 2d liquor is sufficiently heated in the copper to be admitted to the mash-tun to make the 2d mash. As soon as the cock of the copper is opened, the fire is damped by opening the fire-door, and the engine is set to work to pump up a small quantity of the first wort by the pump K from the under-back, into a small back at the top of the house (not seen in the plate, being before the copper) into which the pipe *f* delivers. The contents of this back are let down the instant the copper is empty, to preserve the bottom from burning, and the pump continues to work till the whole of the wort is got into the copper. The hops are now drawn up in bags to the copper head by the tackle I, and their seams being ripped open the contents are thrown into the copper at the man-hole, or door, in the crown of it. This man-hole is closed by an iron lid, fitting steam-tight, and fastened by screws to keep it shut close and retain the steam. The fire beneath the copper is then urged very strongly to boil the first wort, and the steam rising up from it bubbles up through the liquor (water) in the pan, so as to heat that also. The rowser is all this time at work to prevent the hops burning to the copper bottom. During the boiling the second mash has been going on, and when completed, the second wort is run off into the under-back; and as soon as the boiling is completed the fire is damped, and the wort, together with the hops, are run into the jack-back (not shewn in the plate). Here the hops are separated from it by the perforated false bottom, with which the jack-back is provided; and the wort is by the pump K raised up to the coolers L. The instant the first wort quitted the boiler the liquor (water) in the copper-pan was let down into the copper, and the second wort was pumped up from the under-back to the pan. In a few minutes the third liquor acquires the proper heat (having been in the pan during two boilings), and is then run into the mash-tun to make the third mash; and the second wort is immediately let down from the pan into the copper to be boiled. The copper-pan now for the first time remains empty until the third mash is concluded: and then the third wort is thrown up by the pump into it. As soon as the second wort gets into the copper the fire is urged, and the hops are drawn up in a bucket from the jack-back by the tackle I, and returned to the copper to be boiled over again, and the rowser is set in motion. When the boiling of the second wort is concluded the fire is damped: it is run off into the jack-back, and pumped up to the coolers. The third wort is let down from the pan as soon as the second runs out, and the hops are put into the copper again to boil a third time as soon as they can be got up out of the jack-back. The third wort being boiled is run off into the jack-back,

and in its turn pumped up to the coolers: this concludes the day's brewing.

All these processes are conducted with surprising rapidity, though the copper in many of the large breweries contains 300 barrels. It is filled and emptied six times in the course of the brewing; three times with the liquor (water), and three times for the worts; and with no other exertion of the attendants than opening the several valves and cocks. Some of the breweries have three such coppers placed side by side, and each furnished with its suite of vessels: the operations are still conducted just in the same manner as here described. The mill is kept going all the time of the brewing to grind malt for the next day's mash, which, as fast as it is ground, is received into the bin over the mash-tun. The remainder of the day is spent in preparation for the next brewing. The grains, as soon as they are sufficiently cold, are thrown out of the mash-tun by men with shovels, and carried away in carts, as are also the hops. The engine after the day's work is set to pump up water from the well to the liquor-back for the next day. The copper is cleaned out by men who go down into it with brooms and scrapers to take off any foulness which adheres to its bottom; and after this it is filled, as well as the pan, ready for the next morning. In this manner the brewing is continued through the year, except six or eight weeks in the heat of the summer, when the coppers and other vessels are repaired.

When the worts are cooled down to the proper temperature they are drawn off into the square, or guile-tun, in which all the three worts are mixed together; a quantity of yeast is put in, and the fermentation begins very soon to shew itself by the whole body of the liquor teeming with innumerable small bubbles rising to the surface, each enveloped in a thin film of yeast, which, as the bubbles burst, collect into a head or froth, and float on the top of the liquor. The noise of these bubbles rising through the fluid causes a continual singing, and the whole mass appears as if boiling. By this process the porter acquires its spirituous quality, and is rendered clearer, from the great quantity of mucilaginous matter which is thrown off in the yeast. To free the liquor from this superabundant matter is the object of several of the processes it has gone through. In the mashing it is required to extract from the malt all the saccharum it contains: but the heat at which this must be done is also favourable for extracting a great proportion of the mucilage and glutinous parts of the malt, which must afterwards be separated from the wort. If the heat of the mashing liquor is too low, it will extract so much of these matters that all the subsequent processes can never separate them sufficiently to make the liquor fine; and at the same time it will not extract much saccharum. But by increasing the heat the mucilage becomes in a measure coagulated, and is not extracted in so great a degree, whilst the saccharum is taken up by the wort in a

full proportion. On the other hand, an excessive heat carries this too far, for it makes a complete paste of the malt by melting the gluten and mucilage; and the whole resembles a hasty pudding. This disaster, which the brewer calls *setting the goods*, spoils the whole process, as a great proportion of the water becomes combined with the malt in the state of paste, and will not run off; that portion which does remain unmixed and can be drained out has extracted little or nothing, either of mucilage or saccharum, from the malt. This state of things takes place in a greater or less degree whenever the extracting heat is taken too high; the other extreme we have spoken of. Between these the brewer endeavours to keep, and by his success in this simple point the quality and strength of his beer will be influenced most materially. No precise rules can be given for the actual heats, as they depend upon the nature of the malt, the heat used in drying it, the brown requiring less heat than pale: the quality of the water has also its share; and the quantity of malt mashed at once, because a large mash-tun loses less of its heat during the mashing than the small one; also the temperature of the atmosphere. In the process of boiling, the gross part of the mucilage, necessarily extracted by the wort, is coagulated, and in a manner precipitated, into distinct *fecula*, leaving the liquor which was before thick and muddy comparatively clear between the flakes, which are so large as to be individually visible. The boiling also extracts the bitter of the hops, and concentrates the wort by evaporating a part of the water used in the mashing: on spreading the wort thin in the coolers the *fecula* subside, and are left behind. A second separation of the finer mucilage takes place in the fermentation, and the liquor becomes more clear, at the same time the saccharum is changed into spirit, and it loses its sweetness. When the fermentation has advanced so far that the head of yeast begins to sink, it shews the process is past its greatest pitch, and the brewer must check it, or it would soon be succeeded by a second stage of fermentation which produces vinegar. This is done by the operation of cleansing, in which, as we have before stated, the yeast is carried off as fast as it is produced, and the fermentation gradually subsides: the beer is then conveyed to the store-vats, to be kept till wanted. Here the longer it is kept (provided it had a sufficient share of hops to bear keeping without becoming sour) the finer and better porter it will become: but it is in general, as before stated, sent away in the rough, and cleared by finings. The isinglass used in making these was, some time ago, very expensive, and so difficult to be procured at any rate that it put the brewers to great trouble. Mr. Murdoch of Birmingham at this time invented a preparation of fish-skins which answered the same purpose. For using this preparation Messrs. Brown and Parry, brewers, were prosecuted by the solicitor-general for an infringement of the excise regulations: much interesting information on this

subject will be found in the account of the trial which is printed in Mr. Clennel's *Agricultural Magazine*.

The colouring for porter is made by boiling coarse brown sugar in an iron pan with a small quantity of water, keeping it constantly stirred up; it is then set on fire and burned a few minutes, to give it the colour and flavour which might be obtained from brown malt. The fire is extinguished by putting on a cover. The residuum is now mixed up with water to the consistence of treacle, and makes the colouring, which is put to the beer while working in the square, and gives it the same colour and flavour it would have derived from being brewed from brown malt. Some brewers, to avoid the censures of the public, who restrain them to the use of malt and hops alone, concentrate a quantity of their best first wort, by boiling in the iron pan, and burn this instead of sugar, from which it does not materially differ.

A patent has been lately taken out by M. De Roche for colouring porter by the skins and husks of malt roasted to a coffee colour, and mixing them with the malt before mashing; or by infusing them in the water before brewing; or by mixing them with the beer. This would undoubtedly give colour; but we have some doubts of its communicating the flavour which is required.

PORTER (Francis), of Meath, in Ireland, was educated in France, and was divinity professor in the convent of Isidorus at Rome, where James II. gave him the title of his historiographer. He published *securis evangelica ad hæresis radices posita—pallinodia religionis prætensæ reformatæ—compendium annalium ecclesiasticorum regni Hiberniæ*, 4to.—*systema decretorum dogmaticæ*. &c. He died at Rome, 1702.

PORTERAGE. *s.* (from *porter*.) Money paid for carriage.

PORTES (Philip des), a French poet. He greatly improved the French language, and Henry III. bestowed on him 10,000 crowns, Charles IX. gave him 800 crowns of gold for a poem, and admiral de Joyeuse conferred on him an abbey for a sonnet. Though in high favour, he refused a bishopric. He died 1606. He wrote a translation of the psalms—imitations of Ariosto—christian poems—sonnets—elegies, &c.

PORTEUS (Beilby), a learned and most excellent English prelate, was the youngest but one of nineteen children, and was born at York in May 1731. His father and mother were natives of Virginia; but retired to this country, much to the injury of their private fortune, solely for the laudable purpose of giving every possible advantage of education to their children. Dr. Porteus received the first rudiments of his education at York, from whence he was removed to Ripon, and from this place at a very early age became a member of Christ's college, Cambridge, where he was admitted a sizar.

The private merits and studious accomplish-

P O R T E U S.

ments of Dr. Porteus soon advanced him to a fellowship of his college, and the active exertions of his friends soon afterwards procured him the situation of Esquire Bedell, an office of the university, both advantageous and honourable, but not precisely adapted to the character of his mind or habits of his life. He did not therefore long retain it, but wholly occupied himself with the care of private pupils, among whom was the late lord Grantham.

In the year 1757 he was ordained deacon, and soon afterwards priest. His first claim to notice as an author was his becoming a successful candidate for Seaton's prize for the best English poem on a sacred subject. Upon the great and superior merit of this composition, of which the subject was Death, we might with great propriety and justice dilate. It is an admirable poem, characterised by extraordinary vigour, warm sensibility, genuine piety, and accurate taste.

So much talent was not doomed long to remain in the silent and monastic obscurity of a college. In 1762 he became chaplain to archbishop Secker, and in 1765 married Miss Hodgson, the eldest daughter of Brian Hodgson, esq. of Ashbourne in Derbyshire. His first church preferments were two small livings in Kent, which he soon exchanged for Hunton, in the same county, and a prebend in the cathedral church of Peterborough, an option of the archbishop; and he not long afterwards was promoted to the rectory of Lambeth. In this same year, 1767, he took his doctor's degree at Cambridge, and on this occasion preached the commencement sermon.

From this period Dr. Porteus became more and more an object of public esteem and attention: he divided his time between Hunton, which place he always visited with delight, and left with regret, and Lambeth; and in 1769 he was made chaplain to his majesty, and master of the hospital of St. Cross, near Winchester. In the year 1773 he united with some other highly respectable individuals in respectfully recommending a revision of the liturgy and thirty-nine articles; an application, however, in which they failed.

In 1776 Dr. Porteus was promoted to the bishopric of Chester, where he immediately and effectually distinguished himself by a faithful discharge of the duties of his high station.

In the interval between this period and his promotion to the see of London, the bishop evinced his zeal and ardour for the promotion of piety, benevolence, and the public good, by the part which he took in various matters which were objects of popular discussion. The principal among these were the protestant association against popery; the Sunday debating society; the civilization of the negroes, and the establishment of Sunday schools. In the first of these, at the same time that the bishop demonstrated his universal charity and candour, he was not negligent in guarding those committed to his care against the dangerous and exclusive tenets of popery. In the second, his

exertions effectually put a stop to a very alarming evil, to meetings which were calculated to destroy every moral sentiment, and extinguish every religious principle. With respect to the civilization and conversion of the negroes, he indulged the feeling nearest to his heart; but although he had the happiness to see the final accomplishment of his wishes, his first endeavours were not effectual. The plan of Sunday schools was first introduced by Mr. Richard Raikes, of Gloucester, and as soon as ever the bishop was convinced by time and experience of their real utility and importance, he promoted them in his diocese, and by an admirable letter which he addressed to his clergy, he explained their advantages, and recommended their universal adoption.

In November 1787, immediately after the death of bishop Lowth, Dr. Porteus was elevated to the see of London; and from this time to the termination of his life devoted himself with exemplary zeal and assiduity to the various duties of his exalted office. We regret that our limits will not allow us to attempt even a sketch of his conduct, during this period. Suffice it to say that he was ready in every "good word and work," that he was "instant in season and out of season," and that while he acted with firmness and patriotism as a peer in parliament, he acted with primitive simplicity and zeal as a minister of the gospel. He relieved the distressed, consoled the afflicted, removed the doubts of the wavering, refuted the objections of the infidel, and was a "terror to evil doers," (in whatever stations of life they were found) "and a praise to them that do well." This truly good English bishop died at Fulham, May the 13th, 1807; and was buried in the church-yard of Sundridge in Kent, where he had built and endowed a church at his own expence.

Memoirs of his life have been published by his nephew, the rev. Robert Hodgson, to which we must refer for farther particulars. This gentleman has also published the complete works of the bishop, being principally theological, and highly valuable, in 6 vols. 8vo.

The classical attainments of this prelate, if not acutely critical, or exceedingly profound, were entitled to very considerable esteem. They were ready money; always at hand; he had them when he wanted them. His taste for poetry was exquisite; his theological knowledge various and comprehensive. He was sometimes ignorantly or calumniously denominated a methodist: he was no such thing; his piety was animated but not fanatical, and he was the general friend of religious liberty. The great feature of his character was benevolence, prompt, active, universal benevolence, founded upon the principles of the Christian religion. Though he was a sound churchman, he was not a bigot: he loved good men of all persuasions, and would often express his full conviction of meeting them in that world where the distinction of churchman and dissenter will be no more known.

PORTGLAVE. *s.* (*porter* and *glaise*, Fr. and Erse.) A sword-bearer (*Ainsworth*).

PORTGREVE, or **PORTGRAVE**, anciently the principal magistrate in ports and other maritime towns. The word is formed from the Saxon, *port*, and *geref*, a governor. It is sometimes also written *portreve*. It is said by Camden, that the chief magistrate of London was anciently called *port-greve*, which was exchanged by Richard I. for two bailiffs; and these again gave place, in the reign of king John, to a mayor, who was an annually elected magistrate.

PORTICI, a village four miles E.S.E. of the city of Naples, situate on the sea-side, near mount Vesuvius. Here is a palace of the king of Naples, enriched with a vast number of fine statues, and other remains of antiquity, taken out of the ruins of Herculaneum.

PORTICO, in architecture, a kind of gallery on the ground; or a piazza encompassed with arches supported by columns, where people walk under cover. The roof is usually vaulted, sometimes flat. The ancients called it *lacunar*. Though the word *portico* be derived from *porta*, gate, door; yet it is applied to any disposition of columns which form a gallery, without any immediate relation to doors or gates. The most celebrated porticos of antiquity were those of Solomon's temple, which formed the atrium or court, and encompassed the sanctuary; that of Athens, built for the people to divert themselves in, and where-in the philosophers held their disputes and conversations (see **PORCH**); and that of Pompey at Rome.

PORTIO DURA, in anatomy. One branch of the seventh pair of nerves is called *portio dura*, the hard portion, either from its being more firm than the other, or because it runs into the hard part of the skull; and the other the *portio mollis*, or soft portion. Facial nerve. This nerve arises near the pons from the crus of the brain, enters the petrous-portion of the temporal bone, gives off a branch into the tympanum, which is called the *chorda tympani*, and then proceeds to form the *pes anserinus* on the face, from whence the integuments of the face are supplied with nerves. See **FACIAL NERVE**.

PORTIO MOLLIS. Auditory nerve. In anatomy. This nerve arises from the medulla oblongata and fourth ventricle of the brain, enters the petrous portion of the temporal bone, and is distributed, by innumerable branches, not only to the cochlea, but also to the membrane lining the vestibulum and semicircular canals, and is the immediate organ of hearing.

PORTION. *s.* (*portion*, Fr. *portio*, Latin.) 1. A part (*Waller*). 2. A part assigned; an allotment; a dividend (*Waller*). 3. Part of an inheritance given to a child; a fortune (*Prior*). 4. A wife's fortune.

To **PORTION.** *v. a.* (from the noun.) 1. To divide; to parcel (*Rowe*). 2. To endow with a fortune (*Pope*).

PORTIONER. *s.* (from *portion*.) One that divides.

PORTLAND, a peninsula in Dorsetshire, surrounded by inaccessible rocks, except at the landing-place, where there is a strong castle, called Portland Castle, built by Henry VIII. It lies on the S.W. side of Weymouth Bay; and is chiefly noted for its stone, which is used in London for building the finest structures. Its S. extremity, called Portland Point, is in lon. 2. 29 W. Lat. 50. 29 N.

PORTLAND, a seaport of the United States, capital of Cumberland county, in the district of Main. It is seated on a peninsula, and has an excellent harbour, 150 miles N.N.E. of Boston. Lon. 69. 30 W. Lat. 44. 10 N.

PORTLAND ISLANDS, a cluster of islands in the S. Pacific Ocean. They are low, and covered with wood; and the centre one is in lon. 149. 8 E. Lat. 2. 38 S.

PORTLAND STONE, in mineralogy. See **MARMOR**.

PORTLAND VASE, a celebrated funeral vase which was long in possession of the Barberini family; but which was lately purchased for 1000 guineas by the late duke of Portland, from whom it has derived its present name. Its height is about ten inches, and its diameter where broadest six. There are a variety of figures upon it of most exquisite workmanship, in bas-relief of white opaque glass, raised on a ground of deep blue glass, which appears black except when held against the light. It appears to have been the work of many years, and there are antiquarians who date its production several centuries before the Christian era; since, as has been said, sculpture was declining in excellence in the time of Alexander the Great.

Respecting the purpose of this vase, and what the figures on it were meant to represent, there have been a variety of conjectures, which we have no inclination to enumerate.

PORTLANDIA, in botany, a genus of the class pentandria, order monogynia. Corol funnel-form, dilated at top; anthers longitudinal, from four to six; capsule five-sided, retuse, two-celled, two-valved, many-seeded, crowned with the five-leaved calyx. Four species; natives of the West Indies or America.

The only cultivated species is *P. grandiflora*, great-flowered portlandia: with shrubby upright stem, branched, knotty, with a smooth bark cracking longitudinally; buds gummy; anthers five; leaves lance-elliptic, opposite, very entire, shining; flowers axillary, solitary, peduncled, a little nodding, large, beautifully white, most fragrant at night; in the bud yellowish tipped with red. A native of the West Indies; flowers in July and August; may be raised from seeds or cuttings, but requires the heat of a stove.

PORTLINESS. *s.* (from *portly*.) Dignity of mien; grandeur of demeanour; bulk of personage (*Camden*).

PORTLY. *a.* (from *port*.) 1. Grand of mien (*Spenser*). 2. Bulky; swelling (*Shakspeare*).

PORTMAN. *s.* (*port* and *man*.) An inhabitant or burgess, as those of the cinque ports.

PORTMANTEAU, a cloak bag of cloth, leather, &c. in which the cloak, linen, and other habiliments of travellers are disposed and laid on the horse's crupper. The same name is also given to a piece of joiners' work, fastened to the wall in a wardrobe, armoury, &c. proper for the hanging on of cloaks, hats, &c.

PORTO, a small seaport of Italy, in the patrimony of St. Peter. It is the see of a bishop, who is generally a cardinal, and dependent only on the pope. It is 10 miles S.W. of Rome.

PORTO. See **OPORTO**.

PORTO BELLO, a seaport of Terra Firma, on the north coast of the isthmus of Darien, with a large and commodious harbour. It is a very unhealthy place; and the country around it swarms with toads in such multitudes, as hide the surface of the earth. Before the abolition of the trade by the galleons, in 1748, and the introduction of register ships, Porto Bello was the great mart for the rich commerce of Peru and Chili. At the season when the galleons were expected, the product of all the mines, and other valuable commodities, of those countries, were sent by sea to Panama, and thence conveyed across the isthmus, partly on mules, and partly down the river Chagre, to Porto Bello. The town stands close to the sea, on the side of a mountain that surrounds the harbour, which is safe and commodious. It was taken in 1742, by admiral Vernon, who demolished the fortifications; but it has since been strongly fortified. It is 60 miles N. by E. of Panama, and 300 W. of Carthagena. Lon. 79. 50 W. Lat. 9. 33 N.

PORTA PRAYA, a town and bay of St. Jago, one of the Cape Verd islands. The town stands on an elevated plain, and is the residence of the Portuguese governor of the islands. Lon. 23. 29 W. Lat. 14. 54 N.

PORTO DEL PRINCEPE, a seaport on the north coast of Cuba, with a good harbour. Near it are several springs of bitumen. Lon. 78. 15 W. Lat. 21. 52 N.

PORTO REAL, a seaport of Spain, in Andalusia, on the E. side of the bay of Cadiz, near the mouth of the Gaudalete, seven miles E. of Cadiz.

PORTO RICO, an island of the West Indies, 60 miles E. of St. Domingo, belonging to the Spaniards. It is 120 miles long and 40 broad, diversified with woods, valleys, and plains, and watered by springs and rivers, but unhealthy in the rainy seasons. It produces sugar, rum, ginger, cotton, maize, and rice; and there are so many cattle, that they are often killed for the sake of the skins alone. Here are a great number of uncommon trees, and there is a little gold in the N. part of the

island. St. Juan de Porto Rico is the capital.

PORTO SANTO, an island in the Atlantic, the least of the Madeiras, 15 miles in circumference. In 1418, a Portuguese ship, coasting along the African shore, was driven out to sea by a sudden squall, and when they all expected to perish, they discovered this island, which, on account of their escape, they named Porto Santo; and hence they described the island of Madeira. It produces little corn; but there are oxen and wild hogs, and a vast number of rabbits. Its most valuable productions are dragons-blood, honey, and wax. It has no harbour, but good anchorage in the road. Lon. 16. 25 W. Lat. 32. 58 N.

PORTO SEGURO, a province of Brasil, S. of that of Ilheos, and N. of Spiritu Santo. It is very fertile. The capital is of the same name, and seated on the top of a rock, at the mouth of a river that flows into the Atlantic. Lon. 40. 20 W. Lat. 16. 40 S.

PORTO VECCHIO, a seaport of Corsica, seated on a bay on the E. coast of the island, 40 miles S.E. of Ajaccio. Lon. 9. 10 E. Lat. 41. 40 N.

PORTO VENERO, a seaport on the coast of Genoa, at the entrance of the gulf of Spezia. It has a good harbour, and is seated on the side of a hill, at the top of which is a fort, 45 miles S.E. of Genoa. Lon. 9. 38 E. Lat. 44. 5 N.

PORTRAIT. *s.* (*pourtrait*, Fr.) A picture drawn after the life (*Prior*). See **PAINTING**.

To PORTRAIT. *v. a.* (*pourtraire*, French.) To draw; to pourtray (*Spenser*).

PORTRAITURE. *s.* (*pourtraiture*, Fr.) Picture; painted resemblance (*Brown*).

To PORTRAY. *v. a.* (*pourtraire*, French.)

1. To paint; to describe by picture (*Dryden*).

2. To adorn with pictures (*Milton*).

PORTREE, a town of Scotland, on the E. side of the isle of Skye, one of the Hebrides. The inhabitants trade chiefly in black-cattle, sheep, and kelp. It has an excellent harbour, sheltered at its mouth by the isle of Raaza. Lon. 6. 16 W. Lat. 57. 33 N.

PORTRESS. *s.* (from *porter*.) A female guardian of a gate.

PORTSEA, an island between Chichester bay and the harbour of Portsmouth, in Hampshire. It is a low tract about 14 miles in circumference, separated from the mainland on the N. by a creek, over which are two bridges, one for the entrance and the other for the departure of passengers. At the S.W. extremity of it is situate the town of Portsmouth.

PORTSMOUTH, a borough and seaport in Hampshire, with a market on Thursday and Saturday. It is the most considerable haven for men of war, and the most strongly fortified place in England. Its capacious harbour is made by a bay running up between the island of Portsea, on which the town is situate, and the opposite peninsula, having a narrow entrance commanded by the town and fort.

Many of the largest ships are always laid up here; and, in time of war, it is the principal rendezvous of the grand channel fleet. The docks, arsenals, storehouses, barracks, &c. are all of capital magnitude, and kept in the most perfect order. The town is governed by a mayor, and entirely supported by the resort of the army and navy. To the S. of it is the noted road of Spithead, where the men of war anchor when prepared for actual service.—Portsmouth has one spacious church, and two neat chapels; the latter are in a part of the town called Portsea, built on what was formerly called Portsmouth Common, and is now become much larger than the parent town. The number of inhabitants in 1801 was 33,226, exclusive of the males belonging to the army and navy. Portsmouth is the birthplace of the celebrated philanthropist Jonas Hanway. It is 20 miles S.S.E. of Winchester, and 72 S.W. of London. Lon. 1. 6 W. Lat. 50. 47 N.

PORTSMOUTH, the capital of New Hampshire, in Rockingham county, with three churches. It is the largest town and the only seaport in the state, seated on the Piscataqua, two miles from the ocean. Its harbour is one of the finest on the continent, well defended by nature, both against storms and an enemy. It is 50 miles N. by E. of Boston. Lon. 70. 42 W. Lat. 43. 5 N.

PORTSMOUTH, a town of Virginia, in Norfolk county, on the W. side of Elisabeth river, opposite Norfolk; both which towns constitute but one port of entry. It is 107 miles E.S.E. of Richmond. See NORFOLK.

PORTSMOUTH, a town of the state of Ohio, on the E. side of the Sciota, at its confluence with the Ohio. It has a court-house; and is the depot for the merchandise of the settlements of the upper parts of the Sciota. It is 60 miles S. of Chillicothe. Lon. 83. 8 W. Lat. 38. 22 N.

PORTSOY, a seaport of Scotland, in Banffshire, with manufactures of fine linen and sewing thread. Near it are found a vein of serpentine, called Portsoy marble; a species of asbestos, of a greenish colour, which has been wrought into incombustible cloth; and a brilliant kind of granite of a flesh colour. Portsoy stands on a point of land projecting into Murray Frith, nine miles W. of Banff.

PORTUGAL, the most western country of Europe, 350 miles in length, and 120 in breadth; bounded on the W. and S. by the Atlantic, and on the E. and N. by Spain. It is divided into six provinces, Estremadura, Beira, Entre Douero e Minho, Tra los Montes, Alentejo, and Algarva. Though Spain and Portugal are in the same climate, the air of the latter is more temperate than that of the former, on account of the neighbourhood of the ocean. Corn is not plentiful, for little attention is paid to husbandry; and maize, imported from Africa, is used by the peasants instead of wheat. There is a great number of barren mountains, and many fine vales remain in a state of nature: yet there is plenty of

olives, vines, oranges, lemons, nuts, almonds, figs, and raisins; and it is famous for excellent wines. Much salt is made also from the seawater, especially in the bay of St. Ubes, whence a great deal is exported. The manufactures are few and unimportant, but the chief are those of woollen cloth. The foreign trade consists either of the exportation of the produce of the country, or in the merchandise which is received from its foreign settlements; such as sugar, tobacco, rum, cotton, indigo, hides, brasil and other woods for dyeing, and many excellent drugs. Beside these, it has gold, silver, diamonds, and other precious stones from America. The horses of Portugal were formerly in great esteem, but now mules are preferred; the horned cattle are small and lean; sheep are also neglected, and not numerous; but swine abound, and are fed with excellent acorns. Toward the frontiers of Spain there are mountains in which was formerly got gold and silver; and the river Tajo, the Tagus of the ancients, was celebrated by their poets for its golden sands. There are mines of iron, copper, tin, and lead, quarries of marble, and some precious stones. The principal rivers are the Tajo, Douero, Guadiana, Minho, and Mondego. The Portuguese are indolent, and so fond of luxury, that they spend all their wealth in the purchase of foreign merchandise. The women are addicted to gallantry, for which reason the men are jealous of their wives, and allow them but little liberty. The government is monarchical, but the royal authority is limited; for the sovereign cannot raise any more taxes than were settled in 1674. The established religion is the Roman Catholic, and there are two archbishops, and 10 bishops, beside a patriarch; also three severe inquisitions, and yet there are a great number of concealed Jews. The authority of the pope is so great, that the king cannot confer any benefice without his consent. In 1580, there was a failure in the royal line, and Philip II, king of Spain subdued the country; but, in 1640, there was a great revolution, and the crown was conferred on John duke of Braganza (king John IV.) whose descendants still enjoy it. In 1807, in consequence of the French invading Portugal, the whole of the royal family embarked on a fleet in the Tajo, and on December 1st sailed for Brasil, escorted by four British men of war. A regency was previously appointed, but no attempt was made to resist the French, who soon after entered the capital. The French governor, Junot, immediately abolished the regency, and began to treat the country as a conquest to France. In 1808, the English sent an army to aid the Portuguese; and Junot was defeated by sir Arthur Wellesley on the 21st of August at Vimiera. This battle was followed by a convention, and all the French forces were sent by sea to their own country. Fresh forces, however, were sent against the English; and the contending armies of England and France have ever since continued to oppose each other with such mutable success, that it is difficult to conjecture which will be

enabled ultimately to quit the country. The English army is under the command of sir Arthur Wellesley, now earl Wellington, who has all along displayed great judgment, military skill, and heroism. The capital of Portugal is Lisbon.

PORTULACA. Purslane. In botany, a genus of the class dodecandria, order monogynia. Calyx two-cleft, petals five; capsule one-celled, opening transversely all round. Five species; East and West Indies, Egypt, America. The following is the only species cultivated:

P. oleracea. Garden purslane. Stem pro-cumbent, succulent; leaves wedge-form, fleshy, sessile, clustered, entire; flowers sessile, scattered, yellow; stamens from eight to fifteen; seeds round, black. It was formerly much used as a salad and pickle, but is now seldom had recourse to. A native of the Indies and America.

Several species of *talinum* are often confounded with *portulaca*, on account of their general resemblance.

PORTULACARIA, in botany, a genus of the class pentandria, order trigynia. Calyx two-leaved, coloured; petals five; seed one; three-sided and winged. One species, *P. afra*, African purslane tree; stem branched, about three feet high, succulent; leaves succulent, roundish, of a red or purplish colour. It has not been known to flower in our own climate. A native of Africa, and easily increased by cuttings of the stems or branches.

PORTUS (Francis), of Candia, was educated at Ferrara, where he taught, and afterwards at Geneva, the Greek language. He died 1581, aged 70. He wrote additions to Constantine's Greek lexicon, folio; Commentaries on Pindar, Thucydides, Longinus, Xenophon, and other Greek authors. His son *Emilius* was also an able Grecian, and published *Dictionarium Ionicum & Doricum*, Græco-Latin, 2 vols. 8vo.; a translation of *Suidas*, and other learned works. He was professor of Greek at Lausanne and Heidelberg.

PORWIGLE. *s.* A tadpole or young frog not fully shaped (*Brown*).

PORY. *a.* (*poreux*, Fr. from *pore*.) Full of pores (*Dryden*).

POSATA, a town of the island of Sardinia, on the E. coast, 45 miles E.S.E. of Castel Aragonese. Lon. 9. 30 E. Lat. 40. 36 N.

TO POSE. *v. a.* (zepose, Saxon.) 1. To puzzle; to gravel; to put to a stand or stop (*Hammond*). 2. To oppose; to interrogate (*Bacon*).

POSE, in heraldry, denotes a lion, horse, or other beast, standing still, with all his four feet on the ground.

POSEGA, a town of Slavonia, and capital of a county of the same name, taken from the Turks by the Imperialists, in the year 1687: nineteen miles N.E. Gradisca, and twenty N.N.W. Brod. Lon. 18. 59 E. Lat. 45. 36 N.

POSEN, or **POSANIA**, a town of Poland, and capital of a palatinate of the same name, in Great Poland, situated on the Warta, handsome, but not very large. It is enclosed with a double wall, and a deep moat; and on the other side of the Warta, it has two suburbs, namely Szrodka and Waliszewo, which are surrounded with a large morass. Both the city and suburbs are subject to frequent inundations, by the overflowing of the river. The castle stands on an island in the Warta, and is a good structure. It contains several churches and convents, and is the see of a bishop. The bishop's palace stands near the cathedral, which is a fine structure, and between the morasses. This is the first in rank, and the most ancient bishop's see in Poland.

POSER. *s.* (from *pose*.) One that asks questions to try capacities; an examiner (*Bacon*).

POSITED. *a.* (*positus*, Latin.) Placed; ranged (*Hale*).

POSITION. *s.* (*position*, Fr. *positio*, Lat.)

1. State of being placed; situation (*Temple*). 2. Principle laid down (*Hooker*). 3. Advancement of any principle (*Brown*). 4. (In grammar.) The state of a vowel placed before two consonants, as, *pompous*.

POSITION, in astronomy, relates to the sphere. The position of the sphere is either right, parallel, or oblique; whence arise the inequality of days, the difference of seasons, &c.

POSITION (Circles of), are circles passing through the common intersections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any star, or other point in the heavens; used for finding out the position or situation of any star. These are usually counted six in number, cutting the equator into twelve equal parts which the astrologers call the celestial houses.

POSITION, in arithmetic, called also false position, or supposition, or rule of false, is a rule so called, because it consists in calculating by false numbers supposed or taken at random, according to the process described in any question or problem proposed, as if they were the true members, and then from the results, compared with that given in the question, the true numbers are found. It is sometimes also called trial-and-error, because it proceeds by trials of false numbers, and thence finds out the true ones by a comparison of the errors.

Position is either single or double.

Single position is when only one supposition is employed in the calculation. And

Double position is that in which two suppositions are employed.

To the rule of position properly belong such questions as cannot be resolved from a direct process by any of the other usual rules in arithmetic, and in which the required numbers do not ascend above the first power: such, for example, as most of the questions, usually brought to exercise the reduction of simple equations in algebra. But it will not bring out true answers when the numbers sought ascend above the

first power; for then the results are not proportional to the positions. See ARITHMETIC.

POSITION (Centre of), the same as CENTRE OF GRAVITY; which see.

POSITIONAL. *a.* (from *position*.) Respecting position (*Brown*).

POSITIVE. *a.* (*positivus*, Latin.) 1. Not negative; capable of being affirmed; real; absolute (*Locke*). 2. Absolute; particular; direct; not implied (*Bacon*). 3. Dogmatical; ready to lay down notions with confidence (*Rymer*). 4. Settled by arbitrary appointment (*Hooker*). 5. Having the power to enact any law (*Swift*). 6. Certain; assured: as, *he was positive as to the fact*.

POSITIVE DEGREE, in grammar, is the adjective in its simple signification, without any comparison.

POSITIVE ELECTRICITY. In the Franklinian system, all bodies supposed to contain more than their natural quantity of electric matter are said to be positively electrified; and those from whom some part of their electricity is supposed to be taken away are said to be electrified negatively. These two electricities being first produced, one from glass, the other from amber or rosin, the former was called vitreous, the other resinous, electricity. See ELECTRICITY.

POSITIVELY. *ad.* 1. Absolutely; by way of direct position (*Bacon*). 2. Not negatively (*Bentley*). 3. Certainly; without dubitation (*Dryden*). 4. Peremptorily; in strong terms (*Sprat*).

POSITIVENESS. *s.* (from *positive*.) 1. Actuality; not mere negation (*Norris*). 2. Peremptoriness; confidence (*Gov. of Tongue*).

POSITIVITY. *s.* (from *positive*.) Peremptoriness; confidence. A low word (*Watts*).

POSITURE. *s.* (*positura*, Latin.) The manner in which any thing is placed (*Bramhall*).

POSNET. *s.* (from *bassinet*, French.) A little basin; a porringer; a skillet (*Bacon*).

POSSE COMITATUS, in law, signifies the power of the county, or the aid and assistance of all the knights, gentlemen, yeomen, labourers, servants, apprentices, &c. and all others within the county that are above the age of fifteen, except women, ecclesiastical persons, and such as are decrepit and infirm. This posse comitatus is to be raised where a riot is committed, a possession kept upon a forcible entry, or any force of rescue used contrary to the king's writ, or in opposition to the execution of justice; and it is the duty of all sheriffs to assist justices of the peace in the suppression of riots, &c. and to raise the posse comitatus, or to charge any number of men for that purpose.

To POSSESS. *v. a.* (*possessus*, Latin.) 1. To have as an owner; to be master of; to enjoy or occupy actually (*Carew*). 2. To seize; to obtain (*Hayward*). 3. To give possession or command of any thing; to make master of

(*Shakspeare*). 4. To fill with something fixed (*Addison*). 5. To have power over, as an unclean spirit (*Roscommon*). 6. To affect by intestine power (*Shakspeare*).

POSSE/SSION. *s.* (*possession*, French; *possessio*, Latin.) 1. The state of owning or having in one's own hands or power; property (*Milton*). 2. The thing possessed (*Temple*).

POSSESSION is two-fold; actual, and in law: actual possession is, when a man actually enters into lands and tenements to him descended; possession in law is, when the lands or tenements are descended to a man, and he has not as yet actually entered into them.

To POSSE/SSION. *v. a.* To invest with property: obsolete (*Carew*).

POSSE/SSIONER. *s.* (from *possession*.) Master; possessor (*Sidney*).

POSSESSIVE. *a.* (*possessivus*, Latin.) Having possession.

POSSESSIVE, in grammar, a term applied to pronouns which denote the enjoyment or possession of any thing, either in particular or in common: as, *meus*, mine, and *tuus*, thine; *noster*, ours, and *vester*, yours.

POSSE/SSOR. *s.* (*possessor*, Latin; *posseur*, French.) Owner; master; proprietor (*Law*).

POSSESSORY. *a.* (*possessoire*, Fr. from *possess*.) Having possession (*Howell*).

PO/SSET. *s.* (*posca*, Latin.) Milk curdled with wine or any acid (*Suckling*).

To PO/SSET. *v. a.* To turn; to curdle: as milk with acids: not used (*Shakspeare*).

POSSIBILITY. *s.* (*possibilit  *, Fr.) The power of being in any manner; the state of being possible (*Norris*).

PO/SSIBLE. *a.* (*possible*, French; *possibilis*, Latin.) Having the power to be or to be done; not contrary to the nature of things (*Locke*).

PO/SSIBLY. *ad.* (from *possible*.) 1. By any power really existing (*Milton*). 2. Perhaps without absurdity (*Clarendon*).

POST. *s.* (from the Latin, *positus*, set or placed.) 1. A hasty messenger; a courier who comes and goes at stated times (*Ben Jonson*). 2. Quick course or manner of travelling (*Dryden*). 3. Situation; seat (*Burnet*). 4. Military station (*Addison*). 5. Place; employment; office (*Collier*). 6. A piece of timber set erect (*Wotton*).

Post is, in the opinion of many, derived from horses for the conveyance of dispatches, being *positi*, or placed at convenient distances, as relays or changes for those fatigued, and unable to proceed the whole journey with the desired speed. Hence it has become the practice to term horses employed for this and similar purposes, post-horses; their riders, post-boys; the houses for the reception of letters thus conveyed, post-offices; and even the drivers of chaises, postilions; and their vehicles post-chaises; it is natural, besides, to say, he who continues a journey on fresh horses, without stopping for more than necessary refreshment, rides post. The spaces between certain inns, for the reception of travellers in England,

forming a post, varies from twelve to fifteen miles, beyond which it is deemed imprudent to urge a horse, without a long interval of repose; and the charges per mile for horses furnished from those inns have occasioned continual discontent, and frequent general meetings of certain classes of the public.

Before the establishment of a system for the conveyance of important intelligence, and in the earliest state of society, it may be supposed, horses were seized, or, to use a modern term, put into requisition where they were wanted; though it is still more probable, that men were tutored to run from station to station, as is now the practice in the Eastern nations, whose couriers fly their prescribed distance with astonishing velocity, and delivering their dispatches to fresh persons, they are by this means conveyed almost as rapidly as by horses. The emperor Trajan appears to have been the first who ordained the keeping of horses for this purpose only, and the example has appeared so rational to succeeding generations, that it is highly probable posting of every description has now reached its full possible perfection.

It was customary in ancient times to convey information by boats, and in chariots, exclusive of on foot and horseback; nay, even pigeons have been taught to fly from place to place, with letters attached to them: in England, men who conveyed letters were called carriers, which was certainly, in the then state of the roads, a much more appropriate term than the present, implying, in one acceptation, exceeding swiftness. England appears to be the first country in Europe which formed a regular establishment for this purpose: though it was not till a late period that it assumed any thing like a regular form even here. In the reign of Edward VI., however, some species of post must have been set up, as an act of parliament passed in 1548, fixing the rate of post-horses at one penny per mile: the post-horses here referred to were, it is probable, chiefly for travelling, and the carriage of letters or packets only an occasional service. In 1581, we find in Camden's Annals mention made of a chief post-master for England being appointed. How his office was managed, does not clearly appear; the limited state of the correspondence of the country probably rendered it of trifling consequence. King James I. originally erected a post-office under the controul of one Matthew de Quester, or de l'Equester, for the conveyance of letters to and from foreign parts; which office was afterwards claimed by lord Stanhope, but was confirmed and continued to William Frizel and Thomas Witherings, by king Charles I., in 1632. Previous to this time it would appear that private persons were in the habit of conveying letters to and from foreign parts; all such interference with the postmaster's office is, therefore, expressly prohibited. King Charles, in 1635, erected a letter-office for England and Scotland, under the direction of the above Thomas Witherings. The rates

of postage then established were, two-pence for every single letter for a distance under 80 miles; four-pence from 80 to 140 miles; six-pence above 140 miles. The allowance to the post-masters on the road for horses employed in these posts was fixed at two-pence halfpenny per mile for every single horse. All private inland posts were discharged at this time; and in 1637, all private foreign posts were in like manner prohibited. The posts thus established, however, extended only to a few of the principal roads; and the times of transmission were not in every case so certain as they ought to have been.

Witherings was superseded for abuses in the execution of his offices in 1640, and they were sequestrated into the hands of Philip Burlamachy, to be exercised under the care and oversight of the king's principal secretary of state. On the breaking out of the civil war, great confusions and interruptions were necessarily occasioned in the conduct of the letter-office; but it was about that time that the outline of the present more extended and regular plan seems to have been conceived by Mr. Edmond Prideaux, who was afterwards appointed attorney-general to the commonwealth. He was chairman of a committee in 1642, for considering the rate of postage to be set upon inland letters; and some time was appointed post-master by an ordinance of both houses of parliament, in the execution of which office he first established a weekly conveyance of letters into all parts of the nation. In 1653, this revenue was farmed for 10,000*l.* for England, Scotland, and Ireland; and after the charge of maintaining post-masters to the amount of 7000*l.* per annum was saved to the public. Prideaux's emoluments being considerable, the common council of London endeavoured to erect another post-office in opposition to his; but they were checked by a resolution of the house of commons, declaring that the office of postmaster is, and ought to be, in the sole power and disposal of the parliament. This office was farmed by one Mauby, in 1654. In 1656, a new and regular general post-office was erected by the authority of the protector and his parliament, upon nearly the same model that has been ever since adopted, with the following rates of postage: for 80 miles distance, a single letter two-pence; for a greater distance, not out of England, three-pence; to Scotland four-pence. By an act of parliament passed soon after the Restoration in 1660, the regulations settled in 1656 were re-established, and a general post-office similar to the former, but with some improvements, was erected. In 1663, the revenue of the post-office was found to produce 21,500*l.* annually. In 1685, it was made over to the king, as a branch of his private income, and was then estimated at 65,000*l.* per annum. The year after the Revolution, the amount of the post-office revenue was 90,504*l.* 10*s.* 6*d.* At the Union, the produce of the English post-office was stated to be 101,101*l.* In 1711, the

P O S T.

former establishments of separate post-offices for England and Scotland were abolished; and by the stat. 9 Anne, c. 10. one general post-office, and one postmaster-general, were established for the whole united kingdom; and this postmaster was empowered to erect chief letter-offices at Edinburgh, at Dublin, at New York, and other proper places in America, and the West Indies. The rates of postage were also increased at this time, as follows: in England, for all distances under 80 miles, three-pence; above 80 miles, four-pence. From London to Edinburgh, six-pence. In Scotland, under 50 miles, two-pence; from 50 to 80 miles, three-pence; above 80 miles, four-pence. In Ireland, under 40 miles, two-pence; above 40 miles, four-pence. By the above act, all persons, except those employed by the postmaster, were strictly prohibited from conveying letters. That year the gross amount of the post-office was 111,461l. 17s. 10d. The net amount, on a medium of the three preceding years, was, in the printed report of the commissioners for the equivalent, stated to be for England, 62,000l., and for Scotland, 2000l. In 1754, the gross revenue of the post-office for Great Britain amounted to 210,663l.; in 1764, to 281,535l.; and in 1774 to 345,321l. The privilege of franking letters had been enjoyed by members of parliament from the first erection of the post-office; the original design of this exemption was, that they might correspond freely with their constituents on the business of the nation. By degrees the privilege came to be shamefully abused, and was carried so far, that it was not uncommon for the servants of members of parliament to procure a number of franks for the purpose of selling them; an abuse which was easily practised, as nothing more was required for a letter's passing free than the subscription of a member on the cover. To restrain these frauds, it was enacted, in 1764, that no letter should pass free unless the whole direction was of the member's writing, and his subscription annexed. Even this was found too great a latitude; and by a new regulation in 1784, no letter was permitted to go free, unless the date was marked on the cover, in the member's own hand-writing, and the letter put into the office the same day. Each member, too, was restricted to the sending of ten and the receiving of fifteen letters. That year the rates of postage were raised in the following proportions: an addition of one penny for a single stage; one penny from London to Edinburgh; one penny for any distance under, and two-pence for any distance above 150 miles. An addition to the revenue of 120,000l. was estimated to arise from these regulations and additional rates. In all the statements of duties upon postage of letters given in this account, the rates mentioned are those upon single letters: double letters pay double, treble letters treble, an ounce weight quadruple postage; all above are charged by the weight, in the same proportion.

About the year 1784, a great improvement

was made in the mode of conveying the mails, upon a plan first suggested in 1782, by Mr. John Palmer. Diligences and stage-coaches, he observed, were established to every town of note in the kingdom; and he proposed that government, instead of sending the mails in the old mode by a boy on horseback, and in carts, should contract with the masters of these diligences to carry the mail, along with a guard for its protection. This plan, he shewed, could not fail to ensure much more expeditious conveyance, the rate of travelling in diligences being far quicker than the rate of the post; and it was easy to carry it into execution with little additional expence, as the coach-owners would have a strong inducement to contract at a cheap rate for conveying the mail, on account of the additional recommendation to passengers, their carriages would thereby acquire in point of security, regularity, and dispatch. Though government heartily approved of this plan, and the public at large were satisfied of its utility, yet, like all new schemes, however beneficial, it met with a strong opposition: it was represented by a number of the oldest and ablest officers in the post-office, not only as impracticable, but dangerous to commerce and the revenue. Notwithstanding this opposition, however, it was at last established, and gradually extended to many different parts of the kingdom; and, upon a fair comparison, it appeared that the revenue was very considerably improved, though Mr. Palmer's numerous reforms, and the great number of new appointments which they rendered necessary, greatly increased the former expence of management. The conveyance of the mails on the new plan was contracted for, after the two first years trial, at 20,000l. per annum less than the sum first estimated by Mr. Palmer. Those that have travelled in these vehicles need not be informed of their rapid motions, nor of the constant uninterrupted assiduity of the coachmen, the guards, the officers of the different post-towns, and even of the hostlers, to expedite their progress, and to those who have not, and foreigners, the regulations under which they are placed must give an exalted idea of the commercial character of the British nation.

At eight o'clock in the evening of every day, the mail coaches depart from London, freighted with such letters and packets as have been conveyed during the day, either to the office in Lombard-street or to that place from the various receiving-offices scattered in every direction, by the letter-carriers, who walk through their districts ringing a bell from five o'clock to six, to collect those letters which have been delayed to that late hour. The coaches, which proceed to London from all parts of the kingdom, regulate their movements so as to arrive by six o'clock each morning, and from that time the sorters at Lombard-street are employed in preparing the letters for the different carriers waiting to receive them, who generally complete their delivery by twelve at noon.

P O S T.

Newspapers are conveyed gratis to all parts of the country, and if frivolous, vexatious, or malicious letters are sent through the medium of the post-office, upon a proper representation the money is returned; persons are also appointed to open such letters as may be directed to individuals improperly, or who cannot be found, when they are carefully inclosed in an envelope, explaining why the seal has been violated, and returned to the writer. Letters directed to any part of England may be sent without paying; or the receiver will take the postage, and the receipt, or non-payment, is explained to the carriers by marks stamped on the letter; but all letters sent out of England must be paid for on putting them into the office. Other marks, pointing out the day and hour of putting the letter into the receiver's hands, prevent the possibility of neglect without discovery; and so great is the vigilance of the officers, that though millions of money pass through the post-office, it is a very rare circumstance that dishonesty is discovered in the sorters or carriers: when an individual commits a theft of this description, he is pursued with unrelenting severity to punishment, and the office makes good the loss.

The present establishment of the general post-office for Great Britain, consists of a postmaster-general, to the duties of which station there have, for many years past, been two persons appointed, under the title of joint postmaster-general; a secretary; upwards of 150 assistants and clerks for the head letter-office in London, under the direction of a superintending president of the inland letter department; and a comptroller of the foreign-letter office. Near 600 deputy-postmasters, throughout the kingdom, act under one principal, and nine riding surveyors. There are also distinct offices and clerks; acting under an accountant-general and a receiver-general; as well as a separate establishment for the two-penny, formerly the penny-post, which, since the abolition of Mr. Palmer's appointment of surveyor and comptroller-general, has been new modelled and greatly improved in all its branches. There is likewise a postmaster-general of Scotland, with the secretary, comptroller, surveyors, and a separate establishment of all the requisite officers and clerks at Edinburgh, acting under the orders of the joint postmaster-general in London. The annual expence of management is about 150,000*l.* and the gross produce exceeds 700,000*l.* a year.

The general postmaster is not like a common carrier, and is not answerable for the loss of any money by post, nor can the country postmaster add any charge to the postage for carrying the letters out to the inhabitants of the town. The case has been several times tried and decided. A principal object in the erection of the post-office was in order to have the means of inspecting letters of individuals, and discovering attempts against the government, (see the Ordinance, 1657); and now letters may be opened by an order from a secretary of state. For this

and other purposes, there are several penalties levied upon persons carrying or sending letters by private conveyance. Letters coming by private ships from abroad, and even letters belonging to the owners, must also pass through the post-office. Many attempts have been made by postmasters in country towns to charge an halfpenny or penny each letter, on delivery at the houses in the town, above the parliamentary rates, under pretence that they were not obliged to carry letters out of the office gratis; but it has been repeatedly decided, that such demand is illegal, and that they are bound to deliver the letters to the inhabitants within the usual and established limits of the town, without any addition to the rate of postage. 5 Bur. 5709. See FRANKING, LETTER, NEWSPAPER, &c.

POST (Two-penny), a post established for the benefit of London, and other parts adjacent, whereby any letter or small parcel is speedily and safely conveyed to and from all places within the bills of mortality, or within ten miles of the city. It is now managed by the general post-office, and receiving-houses are established in most of the principal streets for the more convenient transmission of the letters.

Letters were originally conveyed by this office at the rate of one penny; but the rate has been lately raised to two-pence, and for letters off the stones the rate is three-pence. By means of this post, letters from London sent only ten miles into the country are delivered three times a day; and letters from such places are delivered either thrice or twice a day, according to the distance.

POST, a station, particularly a military station. Any place where persons are set or placed upon particular occasions may be termed a post; but the word in this view is now chiefly restricted to military operations, and means any place or situation where soldiers are stationed. Thus the detachments established in front of the army are termed the out-posts; the stations on the wings of the army are said to be the posts of honour, as being the most conspicuous and most exposed. But in the operations of a campaign, a post properly signifies any spot of ground capable of lodging soldiers, or any situation, whether fortified or not, where a body of men may make a stand and engage the enemy to advantage. The great advantages of good posts, in carrying on war, as well as the mode of securing them, are only learnt by experience.

To POST. *v. n.* (*poster*, French; from the noun.) To travel with speed (*Walsh*).

To POST. *v. a.* 1. To fix opprobriously on posts (*K. Charles*). 2. To place; to station; to fix (*Addison*). 3. To register methodically; to transcribe from one book into another. (See BOOKKEEPING.) 4. To delay; obsolete (*Shakspeare*).

POST (Francis), a painter, born at Haerlem, where he also died, 1680. He was in 1647 in the West Indies, employed most successfully in delineating the beauties and the scenery of that quarter of the globe.

POS

POSTAGE. *s.* (from *post*.) Money paid for conveyance of a letter (*Dryden*).

POSTBOY. *s.* (*post* and *boy*.) Courier; boy that rides post (*Tatler*).

To POSTDATE. *v. a.* (*post*, after, Latin, and *date*.) To date later than the real time.

POSTDILUVIAN. *a.* (*post* and *diluvium*, Latin.) Posterior to the flood (*Woodward*).

POSTDILUVIAN. *s.* (*post* and *diluvium*, Latin.) One that lived since the flood (*Grew*).

POSTER. *s.* (from *post*.) A courier; one that travels hastily (*Shakspeare*).

POSTERIOR. *a.* (*posterior*, Latin.) 1. Happening after; placed after; following. 2. Backward (*Pope*).

POSTERIOR ANNULARIS, in anatomy, an external interosseal muscle of the hand, that extends and draws the ring finger inwards.

P. INDICIS, an internal interosseal muscle of the hand, that extends the fore finger obliquely, and draws it outwards.

P. MEDII, an external interosseal muscle of the hand, that extends the middle finger, and draws it outwards.

POSTERIORES. *s.* (*posteriora*, Latin.) The hinder parts (*Swift*).

POSTERIORITY. *s.* (*posteriorité*, French; from *posterior*.) The state of being after: opposite to *priority* (*Hale*).

POSTERITY. *s.* (*posteritas*, Latin.) Succeeding generations; descendants (*Smalridge*).

POSTERN. *s.* (*posterne*, Dutch.) A small gate; a little door (*Fairfax*).

POSTEXISTENCE. *s.* (*post* and *existence*.) Future existence (*Addison*).

POSTHACKNEY. *s.* (*post* and *hackney*.) Hired posthorses (*Wotton*).

POSTHASTE. *s.* (*post* and *haste*.) Haste like that of a courier (*Hakewill*).

POSTHORSE. *s.* (*post* and *horse*.) A horse stationed for the use of couriers (*Shakspeare*).

POSTHOUSE. *s.* (*post* and *house*.) Post-office; house where letters are taken and dispatched (*Watts*).

POSTHUMOUS. *a.* (*posthumus*, Latin.) Done, had, or published after one's death (*Addison*).

POSTIC. *a.* (*posticus*, Latin.) Backward (*Brown*).

POSTIL. *s.* (*postille*, Fr. *postilla*, Lat.) Gloss; marginal notes.

To POSTIL. *v. a.* (from the noun.) To gloss; to illustrate with marginal notes (*Bacon*).

POSTILLER. *s.* (from *postil*.) One who glosses or illustrates with marginal notes (*Br.*).

POSTILION. *s.* (*postillon*, French.) 1. One who guides the first pair of a set of six horses in a coach (*Tatler*). 2. One who guides a postchaise.

POSTLIMINIOUS. *a.* (*postliminium*, Lat.) Done or contrived subsequently (*South*).

POSTMASTER. *s.* (*post* and *master*.) One who has charge of public conveyance of letters (*Spectator*).

POSTMASTER-GENERAL. *s.* He who presides over the posts or letter-carriers.

POT

POSTMERIDIAN. *a.* (*postmeridianus*, Lat.) Being in the afternoon (*Bacon*).

POSTOFFICE. *s.* (*post* and *office*.) Office where letters are delivered to the post; a post-house (*Swift*).

To POSTPONE. *v. a.* (*postpono*, Latin.) 1. To put off; to delay (*Rogers*). 2. To set in value below something else (*Locke*).

POSTSCRIPT. *s.* (*post* and *scriptum*, Lat.) The paragraph added to the end of a letter (*Addison*).

To POSTULATE. *v. a.* (*postulo*, Latin.) *postuler*, French.) To beg or assume without proof (*Brown*).

POSTULATE, in mathematics, &c. is described to be such an easy and self-evident supposition, as needs no explication or illustration to render it intelligible; as that a right line may be drawn from one point to another.

POSTULATION. *s.* (*postulatio*, Latin.) The act of supposing without proof; gratuitous assumption (*Hale*).

POSTULATORY. *a.* (from *postulate*.) 1. Assuming without proof. 2. Assumed without proof (*Bacon*).

POSTULATUM. *s.* (Latin.) Position assumed without proof (*Addison*).

POSTURE. *s.* (*posture*, French; *positura*, Latin.) 1. Place; situation (*Hale*). 2. Voluntary collocation of the parts of the body with respect to each other (*South*). 3. State; disposition (*Clarendon*).

To POSTURE. *v. a.* (from the noun.) To put in any particular place or disposition (*Grew*).

POSTUREMASTER. *s.* (*posture* and *master*.) One who teaches or practises artificial contortions of the body (*Spectator*).

PO'SY. *s.* (contracted from *poesy*.) 1. A motto on a ring (*Addison*). 2. A bunch of flowers (*Swift*).

POT. *s.* (*pot*, French; *potte*, Islandic.) 1. A vessel in which meat is boiled on the fire (*Dryden*). 2. Vessel to hold liquids (*John*). 3. Vessel made of earth (*Mortimer*). 4. A small cup (*Prior*). 5. To go to Pot. To be destroyed or devoured. A low phrase (*L'Estrange*).

To POT. *v. a.* (from the noun.) 1. To preserve seasoned in pots (*Dryden*). 2. To enclose in pots of earth (*Evelyn*).

POTABLE. *a.* (*potable*, French; *potabilis*, Latin.) Such as may be drank; drinkable (*Philips*).

POTABLENESS. *s.* Drinkableness.

POTAGER. *s.* (from *pottage*.) A porringer (*Grew*).

POTAMOGETON. Pond-weed. In botany, a genus of the class tetrandria, order tetragynia. Calyxless; petals four; styleless; seeds four. Thirteen species; almost all of them common to the streams, ponds, muddy or stagnant ditches of our own country.

POTAMON, or **POTAMO**, was a philosopher of Alexandria. He kept a middle course between the scepticism of the Pyrrhonists and the presumption of the dogmatists; but attached himself to none of the schools of philosophy.

of his time. He was the first projector of the eclectic sect; for though that mode of philosophising had been pretty common before, he was the first that attempted to institute a new sect on this principle. Diogenes Laertius relates, that not long before he wrote his *Lives of the Philosophers*, an eclectic sect, *ἐκλεκτικὴ τῆς αἵρεσις*, had been introduced by Potamo, of Alexandria, who selected tenets from every former sect. He then proceeds to quote a few particulars of his system from his eclectic institutes, respecting the principles of reasoning, and certain general topics of philosophical inquiry; from which nothing further can be learned, than that Potamo endeavoured to reconcile the precepts of Plato with those of other masters. As nothing remains concerning this philosopher besides the brief account just referred to in Laertius, an obscure passage in Suidas, and another still more obscure in Porphyry; it is probable that this attempt to institute a school upon the eclectic plan proved unsuccessful. The time when Potamo flourished is uncertain. Suidas places him under Augustus; but it is more probable, from the account of Laertius, that he began his undertaking about the close of the second century.

POTASH, in chemistry, one of the three fixed alkalies, procured from the burnt ashes of vegetables, by combustion in iron or other pots, whence the compound pot-ash. It was long distinguished by the name of vegetable alkali, in consequence of its being chiefly obtained from plants, and being at one time supposed to be peculiar to the vegetable kingdom, which is now well known to be a mistake. It was also called salt of tartar, because it may be procured by burning the salt called tartar. Mr. Kirwan has given it the name of tartarin: Klaproth has called it kali; Dr. Pearson, vegalkali; and Dr. Black, lixiva. By most British chemists it is called as above, potash; although, in common language, this last term rather signifies the carbonat of potash, or potash of commerce.

That potash was known to the ancient Gauls and Germans cannot be doubted, as they were the inventors of soap, which Pliny informs us they composed of ashes and tallow. These ashes (for he mentions the ashes of the beech-tree particularly) were nothing more than pot-ash, though not pure potash. The *noxia*, moreover, referred to by Aristophanes and Plato, appears to have been a ley made of the same kind of ashes. The alchemists were well acquainted with it; and, in every period, it has been very largely employed in chemical researches. It may with justice, however, be affirmed that till Berthollet published his process in the year 1786, chemists had never examined potash in a state of complete purity.

This substance, in its rough state, is prepared by burning wood, or other vegetable matter, and thus reducing them to ashes. The ashes are washed repeatedly with fresh waters, till the liquid comes off perfectly tasteless. The liquids thus obtained are evaporated, and the salt pro-

cured is potash. If this substance be exposed to a red heat, many of the materials which are mixed with it are driven off, and what remains is much whiter, and on account of its colour it is called pearl-ash. In this state it is deemed sufficiently pure for the ordinary purposes of life, though by no means adapted to the purposes of the experimental chemist. Even when apparently freed from all extraneous substances, it is found to possess very different properties after having been subjected to certain processes. In one state it is mild and inactive; in another extremely acrid and corrosive. In the former case it is united with carbonic acid gas, and is hence a carbonat of potash, and not pure potash. When deprived of this acid gas, it is powerful, corrosive, and highly caustic. Different methods have been proposed by different chemists to obtain this substance quite pure: we shall transcribe that given by professor Lowitz of Petersburg. He boils in an iron pot for two or three hours any quantity of potash, with double its weight of quicklime, and eight times the weight of the whole mixture of distilled or rain water. The liquor is to be set by to cool, and then filtered and evaporated, till a thick pellicle arises on the surface. It is then left quiescent till crystals are formed on it, which are crystals of extraneous salts, that are to be separated. The evaporation is to be continued, and the several pellicles removed as fast as they are formed. When the fluid ceases to boil, and no more pellicles arise, it is taken from the fire, and kept stirring till cold. It is then dissolved in double its weight of water; the solution is filtered and evaporated in a glass retort, till regular crystals begin to be deposited. When a sufficient quantity has been formed, the liquid is decanted, and the salt is re-dissolved after it is suffered to drain, in the same quantity of water. The decanted liquor is preserved in a well-closed bottle for several days, till it subsides and becomes clear. It is then re-decanted, evaporated, and crystallized again, and the process repeated as long as the crystals afford with the least quantity of water solutions that are perfectly limpid.

Potash thus obtained is a white solid substance, susceptible of crystallization in long compressed quadrangular prisms, terminating in sharp-pointed pyramids. These crystals, which are only obtained from very concentrated solutions, are soft and deliquescent. The taste is extremely acrid; and so corrosive, that it destroys the texture of the skin the moment it touches it: hence it has derived the name of caustic, and is employed in surgery under the name of potential cautery, for the purpose of opening abscesses, or destroying excrescences. Its specific gravity is about 1.7. By a similar mode to the above, pure soda may be prepared, substituting the carbonat of soda for the pearl-ash. They both possess the following properties:—1. They convert vegetable blues into a green colour. 2. They powerfully attract moisture. 3. They readily dissolve in water, and produce heat during the solution. They are not volatilized by a moderate heat, and

hence are called fixed alkalies. 4. Potash shews no disposition to unite with oxygen, neither is it altered by the action of any of the compounds into which oxygen enters, though it has a strong tendency to combine with several of these compounds. 5. It unites with none of the simple combustibles except sulphur. Carbon and hydrogen do not act upon it at all; neither does it produce any alteration in them; but it acts upon phosphorus with considerable energy.

When three parts of sulphur and one of potash are triturated together in a glass mortar the sulphur acquires a green colour, the mixture becomes hot, and exhales an alliaceous odour. It gradually attracts moisture from the air, and is totally soluble in water. When two parts of potash and one of sulphur are heated in a crucible, they melt and combine, and form a sulphuret of potash. It is of a brown colour, not unlike the liver of animals; and was hence formerly called *hepar sulphuris*, liver of sulphur; but when exposed to the air it soon becomes green, and even white. It is hard, brittle, and has a glassy fracture. Its taste is acrid, caustic, and bitter, and it leaves a brown stain upon the skin.

When sulphuret of potash is exposed to the air, or when it is moistened with water, its properties very soon change. It acquires a green colour, and exhales the odour of sulphuretted hydrogen gas, in consequence of the decomposition of the water. This new-formed substance combines with the sulphuret, and converts it into hydroguretted sulphuret of potash, which is soluble in water, and has a brownish-green colour. Hydroguretted sulphuret is capable of oxydizing, and dissolving almost all the metals.

Potash cannot be combined with phosphorus by any known method; but if the former be dissolved in water, and heated over phosphorus in a retort, the water is gradually decomposed, part of the phosphorus is converted into phosphoric acid, and a great quantity of phosphuretted hydrogen gas is emitted, which takes fire as usual, as soon as it comes in contact with the air of the atmosphere. It was by this process that Geugembre first obtained phosphuretted hydrogen gas.

It does not appear that potash is capable of uniting with azot; but it unites very readily with muriatic acid, forming muriat of potash.

It does not combine with any of the metals; but dissolves a considerable number of the metallic oxyds, and in some cases deprives them of a dose of their oxygen. Lead, tin, nichel, zinc, antimony, tellurium, afford oxyds that are chiefly soluble in this substance.

POTASSIUM, a recently discovered and very singular metal obtained by peculiar management from potash, which in modern chemistry can only be regarded as its oxyd.

For the knowledge we at present possess of the bases of the alkalies we are altogether indebted to Mr. Davy, whose most curious and important experiments upon this subject are to be found in the Philosophical Transactions for 1807 and 1808.

Till this period these substances were necessarily regarded as simple from the impossibility of decomposing them by any known methods. Yet they were long and generally suspected to be compounds, though no chemist was able to follow up and detect their elements. By many the alkaliescent principle was supposed to be nitrogen, as the acidifiable was oxygen; neither of which views are now well known to be strictly correct, and the first altogether erroneous. Morveau and Desormes published an ingenious set of experiments in which they endeavoured to prove that potash (to which these experiments were chiefly directed) was a compound of hydrogen and lime. Darracq, however, with that accuracy which has characterised most of his enquiries, soon disproved this theory, and evinced that the results obtained by Desormes and Morveau were owing, in most cases, to the impurity of the potash with which they had made their experiments; while in others they had drawn wrong inferences from mistaken resemblances.

As soon as voltaic electricity was so far rendered manageable as to be applied with very great power to chemical analyses, Mr. Davy conceived the idea of enlisting this wonderful agency into his service, with a view of endeavouring to obtain a decomposition of the alkalies; and he was the more fully induced to give a full scope and latitude to a series of experiments of this kind from observing that if a neutral substance, or a compound of an acid and an alkali, constituted a part of the voltaic circle, a decomposition of such substance was the result, the acid alone always travelling to the positive side of the chain and the alkali to the negative.

Mr. Davy, in his first attempts to decompose the alkalies, made use of the aqueous solutions, and failed. He next made use of the potash in a state of igneous fusion, which he brought within the sphere of the voltaic battery: with this also he was unsuccessful in the main point; but some brilliant phenomena were produced. The potash appeared a conductor in a high degree: a most intense light was exhibited at the negative wire, and a column of flame, which seemed to be owing to the developement of combustible matter, arose from the point of contact. Mr. Davy next tried several experiments on the electrization of potash rendered fluid by heat, with the hope of being able to collect the combustible matter, but he was still unsuccessful, "and I only," says he, "attained my object by employing electricity as the common agent for fusion and decomposition." Potash perfectly dried by ignition is a non-conductor; by a very slight addition of moisture, which does not perceptibly destroy its aggregation, it is rendered a conductor, and in this state it readily fuses and decomposes by strong electrical powers. A small piece of pure potash was placed upon an insulated disc of platina, connected with the negative side of the battery, in a state of intense activity; and a platina wire, communicating with the positive side, was brought in contact with the upper surface of the alkali, a vivid action took place, and the potash began to fuse at both points of electrization. There was a violent effervescence at the upper surface; at the lower, or negative surface, there was no liberation of elastic fluid; but small globules, having a high metallic lustre, appeared; these were similar in visible character to quicksilver: some of them burnt with explosion and bright flame as soon as they were produced, and others

POTASSIUM.

remained, and were merely tarnished, and finally covered with a white film, which formed on them. "These globules," said Mr. Davy, "numerous experiments soon shewed to be the substance I was in search of, and a peculiar inflammable principle the basis of potash. I found that the platina was in no way connected with the result, except as the medium for exhibiting the electrical powers of decomposition; and a substance of the same kind was produced when pieces of copper, silver, gold, plumbago, or even charcoal, were employed for completing the circuit."

Soda, when acted upon in the same manner, exhibited an analogous result, and these effects equally took place in the atmosphere, and when the alkali was acted upon in the vacuum of an exhausted receiver; but these globules could not in either case be produced from crystallized alkalies. When a globule of the base of potash was exposed to the atmosphere, it immediately attracted oxygen, and a white crust formed upon it, which proved to be pure potash. When the globules were strongly heated and then suspended in oxygen gas, a rapid combustion with a brilliant white flame was produced, and these metallic globules were converted to an alkali, whose weight greatly exceeded that of the combustible matter consumed. When Mr. Davy had thus detected the basis of the fixed alkalies, he had considerable difficulty to preserve and confine them, so as to examine their properties and submit them to experiments. He found, however, at length, that in recently distilled naphtha they may be preserved many days, and that their physical properties may be easily examined in the atmosphere, when they are covered by a thin film of it. Potassium at 60° Fahrenheit is only imperfectly fluid; at 70° it becomes more fluid; and at 100° its fluidity is perfect, so that different globules may be easily made to run into one. At 50° it becomes a soft and malleable solid, which has the lustre of polished silver; and at about the freezing point of water it becomes harder and brittle, and when broken in fragments exhibits a crystallized texture, of perfect whiteness and high metallic splendour. To be converted into vapour, it requires a temperature approaching that of the red heat. It is an excellent conductor of heat, and a perfect conductor of electricity.

Resembling the metals in all these properties, it is, however, remarkably different from any of them in specific gravity; for it will not sink in double distilled naphtha, whose specific gravity is only .770, that of water being considered as 1.000. Mr. Davy has determined by experiment that its specific gravity is to that of mercury as 10 to 223, which gives a proportion to that of water nearly as 6 to 10; so that it is the lightest fluid body known. When this substance is introduced into oxymuriatic acid gas, it burns spontaneously with a bright red light, and muriat of potash is formed. When thrown upon water, it decomposes it with great violence, and an instantaneous explosion is produced with brilliant flame, and a solution of pure potash is the result.

When a globule is placed upon ice, not even the solid form of the two substances can prevent their union; for it instantly burns with a bright flame, and a deep hole is made in the ice, which is found to contain a solution of potash. When a globule is dropped upon moistened turmeric paper, it immediately burns and moves rapidly upon the paper, as if in search of moisture, leaving behind

it a deep reddish brown trace. So strong is the attraction of this basis of potash for oxygen, that it discovers and decomposes the small quantities of water contained in alcohol and ether, even when they are carefully purified. When thrown into the mineral acids, it inflames and burns on the surface. In sulphuric acid, sulphat of potash is formed; in nitrous acid, nitrous gas is disengaged, and nitrat of potash formed. When brought in contact with a piece of phosphorus, and pressed upon, there is a considerable action; they become fluid together, burn, and produce phosphat of potash. When a globule is made to touch a globule of mercury about twice as large, they combine with considerable heat; the compound is fluid at the temperature of its formation: but when cool it appears as a solid metal, similar in colour to silver. If this compound be exposed to air, it rapidly absorbs oxygen; potash which deliquesces is formed; and in a few minutes the mercury is found pure and unaltered.

When a globule of the amalgam is thrown into water, it rapidly decomposes it with a hissing noise, potash is formed, hydrogen disengaged, and the mercury remains free. The basis of potash readily reduces metallic oxys when heated in contact with them. It decomposes common glass by a gentle heat, and at a red heat effects a change even in the purest glass.

Mr. Davy has discovered that sodium or the base of soda, like that of potash, is white, opaque, and has the lustre of silver. The property of welding, which belongs to iron and platina, at a white heat only, is possessed by this substance at common temperatures. It is very similar, in its more obvious properties, to the base of potash; but it has greater specific gravity, being to that of water nearly as nine to ten, or as .9348 to 1.0000. In oxygen gas it produces a white flame, and sends forth bright sparks, occasioning a very beautiful effect. In oxymuriatic gas it burns vividly, with numerous scintillations of a bright red colour. In the quantity of $\frac{1}{100}$, it renders mercury a fixed solid, of the colour of silver, and forms an alloy with tin. When amalgamated with mercury, the amalgam will combine with other metals.

Mr. Davy tried this with iron and platina, and had reason to believe that these latter metals remain in combination with the mercury, even when deprived of the new substance by exposure to the air. From several curious and ingenious experiments to ascertain the proportions of the bases and oxygen in the two fixed alkalies, he concludes that 100 parts of potash consist of about 84 basis, and 16 oxygen; and 100 parts of soda consist of about 76 or 77 basis, and 24 or 23 oxygen; or that potash may be considered as consisting of about 6 parts basis, and 1 of oxygen; and soda of 7 basis, and 2 oxygen. In reply to the question, whether the bases of potash and soda should be called metals, it may be said that they agree with metals in opacity, lustre, malleability, conducting powers as to heat and electricity, and in their qualities of chemical combination. Even their low specific gravity does not appear a sufficient reason for making them a new class; for amongst the metals themselves there are remarkable differences in this respect, platina being nearly four times as heavy as tellurium; while tellurium is not much more than six times as heavy as the basis of soda. Conceiving the basis of the two fixed alkalies to be metals, Mr. Davy has named one potassium, and the other sodium; adopting

POTASSIUM.

that neutral termination which, by common consent, has been applied to other newly discovered metals.

On an examination of the volatile alkali, and after a great number of complex and tedious experiments, Mr. Davy saw reason to conclude that ammonia contains oxygen as an essential ingredient, and that this cannot well be estimated at less than 7 or 8 parts in the hundred: this body may, therefore, in his opinion, be considered as the principle of alkaliescence, with as much reason as the French have made it the principle of acidity. After making some general remarks on the preceding facts, he suggests the probability that the muriatic, fluoric, and boric acids all contain oxygen as one of their constituent principles. The earths of barytes and strontian, as being most analogous to the alkalies, were likewise examined, and both yielded oxygen. In concluding this very important communication, Mr. Davy remarks that an immense variety of objects of research is presented in the powers and affinities of the new metals produced from the alkalies. In themselves, they will undoubtedly prove powerful agents for analysis; and having an affinity for oxygen, stronger than any other known substances, they may possibly supersede the application of electricity to some of the undecomposed bodies. At any rate to use the words of the professor himself: "In sciences kindred to chemistry, the knowledge of the nature of the alkalies, and the analogies arising in consequence, will open many new views; they may lead to the solution of many problems in geology, and show that agents may have operated in the formation of rocks and earths, which have not hitherto been suspected to exist."

M. M. Gay Lussac and Thenard have since discovered that potassium may be obtained much more readily and in larger quantities by the simple action of ignited iron upon potash, which separates the oxygen as effectually as the voltaic circuit. Hence these chemists conceived, and at first strongly asserted, that potassium, instead of being a simple substance, is a compound of potash and hydrogen, the last being obtained from the iron. They have since, however, been sufficiently convinced by other experiments of Mr. Davy's and of their own, and have liberally acknowledged their error.

In various subsequent papers introduced into the Philosophical Transactions this able indagator has pressed the same or similar trains of experiments into the different kinds of earths, and although by no means with equal success, with great ingenuity and many valuable elucidations. The general result of the whole appears to be as follows.

It seems to be sufficiently proved that the fixed alkalies and the alkaline earths are metallic oxys; and the proportion of their bases are nearly as well ascertained as those of several metals known for ages to philosophers, and in common life. That alumine, zircon, glucine, and silex are also metallic oxys, seems highly probable; but their decomposition has not yet been so completely ascertained as to render this point altogether certain; while, as to the metals which, in this case, constitute their bases, we can scarcely be said to have precisely discovered any thing. It is demonstrated that ammonia is a compound of oxygen with hydrogen and nitrogen; and that when the oxygen is removed the hydrogen and nitrogen are capable of entering into a true che-

mical union with mercury, forming a substance peculiarly similar to the amalgams of that body with other metals. It is very probable that the hydrogen and nitrogen are combined as a chemical compound which thus unites with mercury, and that the same compound unites with oxygen to form ammonia. The appearance of amalgamation as well as the analogy of the other alkaline bodies, leads us to suspect that this compound basis is truly of a metallic nature; and that the volatile like the fixed alkalies, and the alkaline earths, is a metallic oxyd: but this basis has not yet been separately exhibited.

Such, in general, is the state of our knowledge upon the constitution of the alkalies and the earths, as extended by the late wonderful discoveries: and such is the line to be drawn between what we have strictly learned as physical truths, and what we have been taught to conjecture upon evidence of a lower nature than that of legitimate induction.

The last of these wonders, the constitution of ammonia, gives rise to various hypotheses. To account for the phenomena of amalgamation with mercury and of reproduction of the alkali, three different theories have been stated. Mr. Davy himself seems to think it possible that hydrogen and nitrogen are both metals, aeriform at common temperatures, as zinc and mercury are when ignited. M. Berzelius suggests that they may be simple bodies not metallic, but forming a metal when united without oxygen, and an alkali when united and oxygenated. Mr. Cavendish submitted a third conjecture, which was that these gasses, in their common form, may be oxys, which when further oxygenated may become metallic.

The singular facts which abound in the decomposition of ammonia appear to strike Mr. Davy as capable of leading to some degree of scepticism respecting the phlogistic and antiphlogistic theories: but he clearly shows that they leave the latter in a much better state than the former. He sees some difficulty in reconciling them to either; but far more difficulty in adjusting them with the former. "If," says he, "we assume the phlogistic hypothesis, then we must assume that nitrogen by combining with one-fourth of its weight of hydrogen can form an alkali, and by combining with one-twelfth more can become metallic. If we reason on the antiphlogistic hypothesis, we must assert that though nitrogen has a weaker affinity for oxygen than hydrogen has, yet a compound of hydrogen and nitrogen is capable of decomposing water." He proceeds to show that the latter difficulty is the lesser one, and though he thinks it cannot be wholly removed, it may yet be diminished by chemical analogies; as for example, by the superior inflammability of certain compounds and the greater oxydability of alloys.

In the formation of an amalgam with ammonia and mercury, the following are very curious facts.

First, mercury is rendered solid by a combination with about $\frac{1}{13500}$ part of its weight of new matter, while its specific gravity is diminished from 13.5 to less than 3, and it retains all its metallic characters, colour, lustre, opacity, and conducting power.

Secondly, it is scarcely possible to conceive that the substance thus producing the amalgam is not metallic in its own nature; yet if so, the hydrogen and nitrogen (as Mr. Davy argues in a subsequent article) must be metallic.

In the Phil. Trans. for 1809, part I. the same subject is again pursued through a variety of ex-

periments on sulphur, phosphorus, carbon, diamond, boracic, fluoric and muriatic acids: for his ultimate views with regard to the last, the reader must turn to our article OXYMURIATIC ACID. In regard to the rest, Mr. Davy thinks he traces the decomposition and formation of nitrogen and perhaps of hydrogen in most of them: he has decomposed most of these, but not all: and the general result of his opinions in this paper, is that all matter is resolvable into metallic or oxygenous substances. The supposed simplicity, however, of the oxymuriatic acid or chlorine had not at this time been ascertained or pursued; this, at least, if it should hold its ground, will give us a third substance.

POTATION. *s.* (*potatio*, Lat.) 1. Drinking bout. 2. Draught (*Shakspeare*). 3. Species of drink (*Shakspeare*).

POTATOE, in botany. See **SOLANUM**.

POTATOES (Canada). See **HELVANTHUS**.

POTATOES (Spanish), a species of **CONVOLVULUS**, which see.

POTATOE BREAD. See **BREAD**.

POTBELLIED. *a.* (*pot* and *belly*.) Having a swollen paunch.

POTBELLY. *s.* (*pot* and *belly*.) A swelling paunch (*Arbutnot*).

TO POTCH. *v. a.* (*pocher*, French.) 1. To thrust; to push (*Shakspeare*). 2. (*pocher*, French.) To poach; to boil slightly (*Wise-man*).

POTCOMPANION. *s.* A fellow-drinker; a good fellow at carousals.

POTENCY. *s.* (*potentia*, Lat.) 1. Power; influence (*Shakspeare*). 2. Efficacy; strength (*Shakspeare*).

POTENGER (John), an English writer, born at Winchester, in 1647. He took the degree of B. A. in Corpus Christi college, Oxford, and entering the temple was called to the bar. He is chiefly known by his Pastoral Reflection on Death, a poem; and The Life of Agricola, from Tacitus. He died, in retirement, at Dorchester, in 1733.

POTENT. *a.* (*potens*, Latin.) 1. Powerful; forcible; strong; efficacious (*Shakspeare*). 2. Having great authority or dominion: as, *potent* monarchs.

POTENTATE. *s.* (*potentat*, Fr.) Monarch; prince; sovereign (*Daniel*).

POTENTIAL. *a.* (*potenciel*, Fr. *potentialis*, Lat.) 1. Existing in possibility, not in act (*Raleigh*). 2. Having the effect without the external actual property (*Shakspeare*). 3. Efficacious; powerful: not in use (*Shakspeare*). 4. In grammar, *potential* is a mood denoting the possibility of doing any action.

POTENTIAL CAUTERY, in medicine, the consuming or reducing to an eschar, any part of the human body by a caustic or metallic salt, &c. instead of a red-hot iron, which last is called the actual cautery.

POTENTIAL, in grammar, an epithet applied to one of the moods of verbs. The *potential* is the same in form with the subjunctive, and is, according to Ruddiman, implied in that mood, for which reason that grammarian rejects it; but others will have it to differ

from the subjunctive in this, that it always implies in it either *possum*, *volo*, or *debeo*. It is sometimes called the permissive mood, because it often implies a permission or concession to do a thing. See **GRAMMAR**.

POTENTIALITY. *s.* (from *potential*.) Possibility; not actuality (*Taylor*).

POTENTIALLY. *ad.* (from *potential*.) 1. In power or possibility; not in act, or positively (*Bentley*). 2. In efficacy; not in actuality (*Boyle*).

POTENTILLA. Cinquefoil: wild-tansy: silver-weed. In botany, a genus of the class icosandria, order polygynia. Calyx ten-cleft, inferior; petals five; seeds roundish, naked, mostly wrinkled, affixed to a small juiceless receptacle. Forty-one species; a few American, the rest European plants; which may be thus subdivided.

A. Leaves pinnate.

B. Leaves in finger-like divisions.

C. Leaves ternate.

The following are cultivated.

1. *P. fruticosa*. Shrubby cinquefoil. Stem erect, bark brown, about three or four feet high; leaves pinnate, alternate: flowers terminal, solitary, peduncled, of a bright yellow or golden colour, highly ornamental. A native of Oeland, England, and Siberia; flowers with us in June and July; and, like the plane-trees, has the extraordinary property of exfoliating its cuticle every year.

2. *P. fragarioides*. Strawberry-leaved cinquefoil. Root tuberous; leaves pinnate and ternate; runners creeping. A native of Siberia.

3. *P. recta*. Upright cinquefoil. Leaves seven and five, lanceolate, coarsely toothed; petals inversely heartshaped, larger than the calyx; stem erect. A native of the south of Europe; flowers in June and July.

4. *P. Monspeliensis*. Montpellier cinquefoil. Leaves ternate; stem branched, erect, about a foot high; peduncles springing out above the joints: flowers white and large, appearing in June. A native of Montpellier.

5. *P. grandiflora*. Great-flowered cinquefoil. Leaves ternate, toothed, a little hairy, and of the same colour on both sides; stem decumbent, longer than the leaves; flowers larger than in the last; appears in July. A native of Switzerland and Siberia.

The first sort may be propagated by suckers, layers, and cuttings; all the rest succeed best by parting the roots or sowing the seeds.

POTENTLY. *ad.* (from *potent*.) Powerfully; forcibly (*Bacon*).

POTENTNESS. *s.* (from *potent*.) Powerfulness; might; power.

POTERIUM. Burnet. In botany, a genus of the class monœcia, order hexandria. Calyx four-leaved; corol four-parted. Male: filaments from thirty to fifty, very long, flaccid. Female: pistil one or two; nut two-celled, coated with the hardened tube of the corol. Five species: Europe and Barbary. The following are cultivated.

1. *P. sanguisorba*. Lesser upland, or com-

mon garden burnet. Found wild on our own dry mountains, and used as a salad herb for winter and spring, from the aromatic warmth of its leaves: root and root-leaves perennial; stalk annual.

2. *P. hybridum*. Sweet burnet. A biennial plant; indigenous to the south of France, Italy, and Barbary.

3. *P. spinosum*. Prickly shrubby burnet. Armed with sharp spines; rises three feet high. A native of the Levant.

The two first should be raised by seeds or parting the roots; the second succeeds best by cuttings.

POTGUN. *s.* A gun which makes a small smart noise. Properly *popgun* (*Swift*).

POTHANGER. *s.* (*pot and hanger*.) Hook or branch on which the pot is hung over the fire.

POTHECARY. *s.* (from *apothecary*.) One who compounds and sells physic.

POTHER. *s.* (*poudre*, French, dust.) 1. Bustle; tumult; flutter (*Guardian*). 2. Suffocating cloud (*Drayton*).

To POTHER. *v. n.* To make a blustering ineffectual effort.

To POTHER. *v. a.* To turmoil; to puzzle (*Locke*).

POTHERB. *s.* (*pot and herb*.) An herb fit for the pot (*Dryden*).

POTHOOK. *s.* (*pot and hook*.) 1. Hooks for fasten pots or kettles with. 2. Ill-formed or scawled letters or characters (*Dryden*).

POTHOS, in botany, a genus of the class tetrandria, order monogynia. Spathe; spadix simple, covered with flowers; calyxless; petals four; berry two-seeded. Twelve species; natives of either of the Indies or South America.

POTIDÆA, a town of Macedonia, situate in the peninsula of Pallene. It became tributary to the Athenians, from whom Philip of Macedonia took it. The conqueror gave it to the Olynthians to render them more attached to his interest. Cassander repaired it, and called it Cassandria, a name which it still preserves.

POTION. *s.* (*potion*, Fr. *potio*, Latin.) A draught; commonly a physical draught (*Wotton*).

POTLID. *s.* (*pot and lid*.) The cover of a pot (*Derham*).

POTOMAC, or PATOMAC, a river of Virginia, which falls into the bay of Chesapeake. On the banks of this river is now erecting the city of Washington, the intended metropolis of the United States. See WASHINGTON.

POTOSI, a rich and populous town of Peru, in the audience of Los Charcos. Here is the best silver mine in all America, in a mountain in the form of a sugar-loaf. Silver was as common in this place as iron is in Europe; but it is almost exhausted, or at least little is got in comparison of what was formerly; and the mountain itself is said to be little better than a shell. The country around is so naked and barren, that the inhabitants get their provisions from the neighbouring pro-

vinces. It is seated at the bottom of the mountain of Potosi, 300 miles S.E. of Arica. Lon. 64. 25 W. Lat. 19. 40 S.

POTSDAM, a city of Upper Saxony, in the middle marche of Brandenburg, with a palace belonging to the king of Prussia. It is seated in an island 10 miles in circumference, formed by the rivers Spree and Havel, and is the most elegant and singular city in Europe. Many new houses, on the finest ancient and modern plans, were raised by Frederic II. and presented to the inhabitants; and the various public buildings display at once great magnificence and taste. In 1795, the beautiful church of St. Nicholas, in the palace-square, was destroyed by fire, together with the surrounding houses, toward which the wind directed the flames. It is 12 miles W. of Berlin. Lon. 13. 46 E. Lat. 52. 52 N.

POTSHERD. *s.* (*pot and sherd*.) A fragment of a broken pot.

POTSTONE. (*topfstein*, German; *pierre ollaire*, Fr.) In mineralogy, a genus of argillaceous earths, somewhat similar to pipe-clay, found in mass of a greenish-grey hue, its internal lustre being glistening and pearly; its fracture curved, foliated and imperfectly slaty; with tabular fragments. It is often translucent on the edges; is soft and greasy to the touch, tough and difficultly refrangible. It is found in beds with serpentine, at Como in the Grison country, and in Saxony. It may be turned in a lathe, and is worked into a variety of vessels. It is also used as a lining for furnaces, being remarkably refractory.

POTT (Percival), an English surgeon, born at London in 1713. At the age of 16 he was bound apprentice to Mr. Nourse, a surgeon of eminence, under whom he made great progress. In 1746 he was elected surgeon to St. Bartholomew's hospital. In 1757 he wrote an account of the Hernia congenita, and next year, *Observations on the fistula lachrymalis*. In 1760 he published a work on wounds and contusions of the head; and in 1764 was elected a fellow of the royal society. The profession is greatly indebted to him for the improvements he has introduced into practice. He died in 1788.

POTTAGE. *s.* (*potage*, Fr. from *pot*.) Any thing boiled or decocted for food (*Genesis*).

POTTER. *s.* (*potier*, Fr. from *pot*.) A maker of earthen vessels (*Mortimer*).

POTTER (Christopher), an English divine, born in Westmorland about 1591. He was of Queen's college, Oxford, and took his degrees in arts and divinity; and in 1626 became provost of his college. In 1635 he was made dean of Worcester, and in 1640 became vice-chancellor of Oxford. He suffered during the civil wars for his attachment to the royal cause, and died in 1646.

POTTER (Paul), or POTER, a Dutch painter, born at Enckuysen in 1625, and died at Amsterdam in 1654. He surpassed most of his profession in the representation of a bright sun upon rural scenery.

POTTER (John), archbishop of Canterbury,

was born at Wakefield in Yorkshire, in 1674. At nineteen he published his *Variantes lectiones et notæ ad Plutarchi, &c.* and the year after was chosen fellow of Lincoln college. In 1697 he published the first vol. of his *Antiquities of Greece*, and this literary pursuit engaged him in a correspondence with Grævius and other learned men abroad. In 1715 he was made bishop of Oxford, and in 1737 he succeeded Dr. Wake in the archbishopric of Canterbury. He died suddenly in 1747. He published an edition of *Lycopipon*, a discourse on church government, &c.

POTTER'S CLAY, in mineralogy. See **ARGIL**.

POTTERY: the art by which plastic earth, more or less simple, is converted into hard brittle vessels of various kinds and forms, and designed for various purposes.

The essential material of pottery is clay, which alone possesses the two requisite qualities of being in its natural state so plastic that with water it becomes a soft uniformly extensible mass, capable of assuming and retaining any form; and when thoroughly dried, and having undergone a red heat for a time, of losing this plasticity, becoming irretentive of water to any considerable degree, hard, close in texture, and able more or less perfectly to confine all liquids contained within its hollow.

Clay, however, as we have already observed in the article **ARGIL**, is in all instances a very compound substance: it owes its plasticity to alumine, which forms a constituent part of it; but the proportion of alumine varies considerably in different species, and almost as much as the other substances with which it is combined.

It may hence be supposed that many of the impure coloured natural clays are of themselves sufficiently mixed with other earths for the potter's use without any addition; but the white and finer clays mostly require dilution with silex in some form or other, which may be done to a considerable extent without taking away the plasticity requisite for working.

The most important circumstances requisite to be considered in selecting the materials for pottery are plasticity, contractility, solidity, and compactness after drying, colour, and fusibility.

The plasticity seems to be simply owing to the proportion of clay used, or relatively to the original plasticity of the clay itself; for all clays are not equally plastic, and the super-added substances in no instance increase this property, and in many cases considerably diminish it.

The texture, including the qualities of hardness and compactness, depends partly on the mixture of siliceous (flinty or sandy) ingredients with the clay, and partly on the heat employed in the burning of the pottery. The purer natural clays are almost infusible in any furnace heat; their hardness is nearly progressive with the intensity of the fire, but they have the essential defects of drying very slowly, of shrinking very considerably, and of becoming rifty

or full of minute cracks when dried, so as on this account to be porous. It is therefore necessary to mix them intimately with any other earth of qualities opposite to those of clay; that is, which absorbs but little water, and quickly parts with it, (qualities directly opposite to plasticity) and which dries compact and close.

The colour of the earths used is also of essential importance in the finer pottery, in which the great desideratum is to find a clay which after burning remains perfectly white. The appearance before burning cannot always be depended upon; for though in general the whitest clays before burning are those that remain white afterwards, it is only in a few districts that clays are to be found that retain a perfect whiteness. Thus there exists at the foot of a range of high hills that directly overlook the Staffordshire potteries, a stratum of white clay to appearance fully equal if not superior to the best Devonshire clays, which cannot be employed for fine pottery, from its acquiring in burning a yellowish cream colour which no art can correct. This colour is supposed to depend on an intermixture of iron.

The fusibility of clays and of other pottery earths is a subject of extreme importance, as it is this property that principally constitutes the difference between common pottery and porcelain.

We have defined porcelain to be a species of pottery ware composed of an earthy mixture which resists complete fusion in a very considerable heat, but has been brought by a less heat than its melting point to a state of incipient fusion, and is thereby rendered extremely hard, sonorous, and semi-transparent, and possesses a semi-conchoidal splintery fracture approaching to the vitreous, which is completely conchoidal. This last is quite a distinctive character between porcelain and pottery, for the fracture of pottery is extremely granular; and hence porcelain may correctly be regarded as a substance of a middle nature between pottery and glass.

From these circumstances it appears probable that no chemical action takes place in any pottery combination till it arrives at the state of porcelain. The most perfect and beautiful porcelains of Japan and China are composed of two distinct earths; one in which silex predominates, and which melts in a strong fire; and another which is infusible *per se*: and by the union of those two earths a porcelain is produced which scarcely vitrifies at the utmost furnace heat which art can excite. This substance possesses the combined excellencies of great hardness, beautiful semi-transparency, exquisite whiteness, where not artificially coloured, strong toughness and cohesion; so that it has strength enough for the purposes for which it is designed when made very thin, and bears sudden heating and cooling without cracking.

Of the beautiful European porcelains which have been made in imitation of the oriental, it does not appear that any of them unite all

POTTERY.

its excellencies. Earthy combinations have been made equally strong, tough, and infusible, and as truly porcelainous when burnt, but they have not quite rivalled the best Japanese in delicate whiteness and lustre. As these last qualities, however, are esteemed most essential, that of infusibility (which indeed is of no great consequence for any of the common uses of porcelain) has been sacrificed; and hence those that make a near approach to the oriental in beauty and delicate lustre, of which many manufactures in different parts of Europe have afforded splendid examples, are frequently found to soften and melt down in an intense heat of a wind-furnace, at which the true Nankin and Japan china undergo no change.

The manufacture of the ordinary pottery is on the whole very simple where a due selection of materials is made; but the ornamental branches of it, such as those of modelling, enamelling, painting, and gilding, which often display exquisite beauty, are accompanied with much delicacy, and require a combination of perseverance, skill, and practical nicety of management, that are rarely equalled in any other chemical manufacture.

An intimate mixture of the ingredients used in pottery is of great importance to the beauty, compactness, and soundness of the ware. Formerly the wet clay and ground flint, or whatever else was employed, were beaten together with long-continued manual labour, no more water being added than was necessary to render the clay thoroughly plastic. This laborious and expensive method has now been laid aside in the larger potteries; and the ingenious method has been substituted of bringing each material first to an impalpable powder, and diffusing them separately in as much water as will bring them to the consistence of thick cream, mixing them in due proportion by measure, and when thoroughly stirred together, evaporating the superfluous water till the mass is brought to a proper consistence for working.

In the Staffordshire process the materials are a fine clay, brought chiefly from Devonshire, and a siliceous stone called chert, or else common flint reduced to powder by heating it red-hot, quenching it in water, and then grinding it by windmills. Each material is passed through fine brass sieves, then diffused in water, mixed by measure, and brought to a plastic state as above.

The wheel and lathe are the chief, and almost the only, instruments made use of: the first for large works, and the last for small. The potter's wheel consists principally in the nut, which is a beam or axis, whose foot or pivot plays perpendicularly on a free-stone sole or bottom. From the four corners of this beam, which does not exceed two feet in height, arise four iron bars, called the spokes of the wheel; which, forming diagonal lines with the beam, descend, and are fastened at bottom to the edges of a strong wooden circle, four feet in diameter, perfectly like the felloe of a coach-wheel, ex-

cept that it has neither axis nor radii, and is only joined to the beam, which serves it as an axis, by the iron bars. The top of the nut is flat, of a circular figure, and a foot in diameter: and on this is laid the clay which is to be turned and fashioned. The wheel, thus disposed, is encompassed with four sides of four different pieces of wood fastened on a wooden frame; the hind-piece, which is that on which the workman sits, is made a little inclining towards the wheel; on the fore-piece are placed the prepared earth; on the side-pieces he rests his feet, and these are made inclining, to give him more or less room. Having prepared the earth, the potter lays a round piece of it on the circular head of the nut, and sitting down, turns the wheel with his feet till it has got the proper velocity; then, wetting his hands with water, he presses his fist or his fingers-ends into the middle of the lump, and thus forms the cavity of the vessel, continuing to widen it from the middle; and thus turning the inside into form with one hand, while he proportions the outside with the other, the wheel constantly turning all the while, and he wetting his hands from time to time. When the vessel is too thick, he uses a flat piece of iron, somewhat sharp on the edge, to pare off what is redundant; and when it is finished, it is taken off from the circular head, by a wire passed underneath the vessel.

The potter's lathe is also a kind of wheel, but more simple and slight than the former; its three chief members are an iron beam or axis three feet and a half high, and two feet and a half diameter, placed horizontally at the top of the beam, and serving to form the vessel upon: and another large wooden wheel, all of a piece, three inches thick, and two or three feet broad, fastened to the same beam at the bottom, and parallel to the horizon. The beam or axis turns by a pivot at the bottom in an iron stand. The workman gives the motion to the lathe with his feet, by pushing the great wheel alternately with each foot, still giving it a greater or lesser degree of motion, as his work requires. They work with the lathe, with the same instruments, and after the same manner, as with the wheel. The mouldings are formed by holding a piece of wood or iron, cut in the form of the moulding, to the vessel, while the wheel is turning round, but the feet and handles are made by themselves, and set on with the hand; and if there be any sculpture in the work, it is usually done in wooden moulds, and stuck on piece by piece on the outside of the vessel.

Handles, spouts, &c. are afterwards fixed on to the moulded piece if required; and it is then set to dry for some days in a warm room, where it becomes so hard as to bear handling without altering its shape. When dry enough it is inclosed along with many others in baked clay cases of the shape of bandboxes, called seggars, which are made of the coarse clays of the country. These are next ranged in the kiln or furnace so as to fill it except a space in the

middle for the fuel. Here the ware is baked till it has remained fully red hot for a considerable time, which in the larger kilns consumes ten or fifteen tons of coals: after which the fire is allowed to go out, and when all is cooled, the seggars are taken out, and their contents unpacked.

The ware is now in a state of biscuit, perfectly void of gloss, and resembling a clean egg-shell. In order to glaze it, which is the next process, the biscuit ware is dipped in a tub containing a mixture of about sixty parts of litharge, ten of clay, and twenty of ground flint, diffused in water to a creamy consistence, and when taken out, enough adheres to the piece to give an uniform glazing, when again heated: for which purpose the pieces are re-packed up in the seggars, with small bits of pottery interposed between each, and fixed in the kiln as before. The glazing mixture fuses at a very moderate heat, and gives an uniform glossy coating, which finishes the process for common white ware; though the painting and gilding require subsequent attention.

POTTING. *s.* (from *pot.*) Drinking (*Shakespeare*).

POTTLE. *s.* (from *pot.*) A liquid measure containing four pints (*Ben Jonson*).

In London it denotes a little tapering basket, for strawberries and other delicate fruits, but of no precise dimensions.

POTTON, a town in Bedfordshire, with a market on Saturday, 12 miles E. of Bedford, and 48 N. by W. of London. Lon. O. 18 W. Lat. 52. 11 N.

POTVALIANT. *a.* (*pot* and *valiant.*) Heated to courage by strong drink.

POTULENT. *a.* (*potulentus*, Latin.) 1. Pretty much in drink. 2. Fit to drink.

POUCH. *s.* (*poche*, French.) 1. A small bag; a pocket (*Sharp*). 2. Applied ludicrously to a big belly, or paunch.

To POUCH. *v. a.* 1. To pocket (*Tusser*). 2. To swallow (*Derham*). 3. To pout; to hang down the lip (*Ainsworth*).

POUCH, in botany. See **SILICLE**.

POUCHMOUTHED. *a.* (*pouch* and *mouthed*.) Blubberlipped (*Ainsworth*).

POVERTY. *s.* (*pauvreté*, French.) 1. Indigence; necessity; want of riches (*Shakespeare*). 2. Meanness; defect (*Bacon*).

POUGET (Francis Amé), a French priest of the oratory, and doctor of the Sorbonne, born at Montpellier in 1666. He was vicar of St. Roch at Paris in 1692, and in that office was said to have converted the celebrated La Fontaine; on which subject he wrote a curious letter published by Desmolets. Colbert, bishop of Montpellier, placed him at the head of a seminary in that town; from which he returned to the capital, where he died in 1723.

POULDAVIS. [*s.* A sort of sail-cloth (*Ainsworth*).

POULT. *s.* (*poulet*, Fr.) A young chicken.

POULTERER. *s.* (from *poult.*) One whose trade is to sell fowls ready for the cook (*Har.*).

POULTICE. *s.* (*pultis*, Latin.) A cataplasm; a soft mollifying application. See **CATAPLASM**.

To POULTICE. *v. a.* (from the noun.) To apply a poultice or cataplasm.

POULTIVE. *s.* A poultice (*Temple*).

POULTRY. *s.* (*poulet*, French.) Domestic fowls (*Dryden*).

POUNCE, the pounded resinous tears of the juniperus communis. See **SANDRAC**.

POUNCE, is also a little heap of charcoal dust, inclosed in a piece of muslin or some other open stuff, to be passed over holes pricked in a work, in order to mark the lines or designs thereof on paper, silk, &c. placed underneath; which are to be afterwards finished with a pen and ink, a needle, or the like. This kind of pounce is much used by embroiderers, to transfer their patterns upon stuffs; by lace-makers, and sometimes also by engravers.

POUNCES, in falconry, the talons or claws of a bird of prey.

To POUNCE. *v. a.* (*pongonare*, Ital.) 1. To pierce; to perforate (*Bacon*). 2. To pour or sprinkle through small perforations (*Bacon*). 3. To seize with the pounces or talons.

POUNCED. *a.* (from *pounce*.) Furnished with claws or talons (*Thomson*).

POUNCETBOX. *s.* (*pounce* and *box*.) A small box perforated (*Shakespeare*).

POUND. *s.* (*pond*, *pund*, Saxon.) 1. A certain weight, consisting in troy weight of twelve, in averdupoise of sixteen ounces. 2. The sum of twenty shillings (*Peacham*). 3. (from *pin*, *an*, Sax.) A pinfold; a prison in which beasts are enclosed (*Swift*).

To POUND. *v. a.* (*punian*, Saxon.) 1. To beat; to grind as with a pestle (*Bentley*). 2. To shut up; to imprison, as in a pound (*Spectator*).

POUNDAGE. *s.* (from *pound*.) 1. A certain sum deducted from a pound (*Swift*). 2. Payment rated by the weight of the commodity (*Clarendon*).

POUNDER. *s.* (from *pound*.) 1. The name of a heavy large pear (*Swift*). 2. Any person or thing denominated from a certain number of pounds: as, a ten pounder, a gun that carries a bullet of ten pounds weight. 3. A pestle (*Ainsworth*).

POUPARTS LIGAMENT. Ligamentum Poupartii. Fallopiian ligament. Inguinal ligament. In anatomy, a strong ligament, or rather a tendinous expansion of the external oblique muscle, going across from the inferior and anterior spinous process of the ilium, to the crista of the os pubis. It is under this ligament, the femoral vessels pass; and when the intestine or omentum passes underneath it, the disease is called a femoral hernia.

POUPETON. *s.* (*poupée*, French.) A puppet or little baby.

POUPICS. *s.* In cookery, veal steaks and slices of bacon (*Bailey*).

To POUR. *v. a.* (*burw*, Welsh.) 1. To let some liquid out of a vessel, or into some place

POU

or receptacle (*Exodus*). 2. To emit; to give vent to; to send forth; to let out; to send in a continued course (*Dup.*).

To **POUR**. *v. n.* 1. To stream; to flow. 2. To rush tumultuously (*Pope*).

POURBUS (Peter and Francis), father and son, two Flemish painters of the 16th century. There are some good pictures of the son in the town-house at Paris. The father died at Antwerp in 1580, and the son at Paris in 1622.

POURER. *s.* (from *pour*.) One that pours. **POURRETIA**, in botany, a genus of the class monadelphia, order polyandria. Calyx five-parted; petals five, lanceolate; drupe dry, one-seeded, large, winged. One species; an arborescent plant of Peru.

POURSELUC, a town of the kingdom of Siam, 280 miles N. of Siam. Lon. 100. 40 E. Lat. 18. 58 N.

POURSUIVANT, or **PURSUIVANT**, in heraldry, the lowest order of officers at arms. The pursuivants are properly attendants on the heralds, when they marshal public ceremonies. Of these, in England, there were formerly many, but at present there are only four, viz. blue-mantle, rouge-cross, rouge-dragon, and portcullice. In Scotland, there is only one king at arms, who is stiled lion, and has no less than six heralds, and as many pursuivants, and a great many messengers at arms under him.

POURZAIN, a town of France, in the department of Puy de Dome, seated on the Sioule, 36 miles N. by E. of Clermont, and 190 S. of Paris. Lon. 3. 15 E. Lat. 46. 21 N.

POURVEYANCE. See **PURVEYANCE**. **POUSSE**, the old word for *pease*.

POUSSIN (Nicholas), an eminent landscape and historical painter, born at Andely in Normandy, in 1594. Inspired with the love of his art, he left his country and went to Italy, where he devoted much of his time to the study of antiques and bas reliefs. Louis XIII. invited him back to Paris, and allowed him to lodge in the Tuilleries. Louis XIV. conferred a pension on him; but the artist being thwarted in his painting the Labours of Hercules, which he began as an ornament for the gallery of the Louvre, he returned again to Rome, where he died of a palsy in 1665.

POUSSIN (Gasper), a painter whose real name was Dughet, but took that of Poussin out of regard to the art of painting, and because his sister married Nicholas Poussin. Sandrart says that Gasper was first employed only to prepare the pallet, pencils, and colours for his great master, he rose to an eminence in landscape-painting unattained by any painter whatever. In representing a land-storm he is truly admirable. He died about 1675, aged 75.

POUT. *s.* 1. A kind of fish; a codfish. 2. A kind of bird (*Carew*).

To **POUT**. *v. n.* (*bouter*, French.) 1. To look sullen by thrusting out the lips (*Shak-*

POW

speare). 2. To shoot out; to hang prominent (*Dryden*).

POZZOLANO. Pozzolino. In mineralogy, a species of **PUTEOLANA**, which see.

POWDER. *s.* (*poudre*, French.) 1. Dust; any body comminuted (*Exodus*). 2. Gunpowder (*Hayward*). See **GUNPOWDER**. 3. Sweet or scented dust for the hair (*Herbert*).

To **POWDER**. *v. a.* (from the noun.) 1. To reduce to dust; to comminute; to pound or grind small. 2. (*poudrer*, Fr.) To sprinkle, as with dust (*Donne*). 3. To salt; to sprinkle with salt (*Cleaveland*).

To **POWDER**. *v. n.* To come tumultuously and violently; a low word (*L'Estrange*).

POWDER, in pharmacy. See **PHARMACY**.

POWDERBOX. *s.* (*powder and box*.) A box in which powder for the hair is kept (*Gay*).

POWDERHORN. *s.* (*powder and horn*.) A horn case in which gunpowder is kept (*Swift*).

POWDER MAGAZINE. See **MAGAZINE**.

POWDERMILL. *s.* (*powder and mill*.) The mill in which the ingredients for gunpowder are ground and mingled (*Arbutnot*).

POWDERPROVER, or **EPROUVETTE**, an instrument contrived for the purpose of ascertaining the strength of gunpowder. There are various contrivances for this purpose, some of a more simple, and some of a more complex and expensive kind. We shall here confine ourselves to powderprovers of the former sort.

M. Regnier invented one in which a small barrel is placed vertically to hold the powder, over which a stopper is held down by a weight suspended beneath it by a cord.

The stopper is connected with a vertical ratchet wheel, with thirty teeth cut on its circumference, against which a spring catch presses; on the edge of the wheel a groove is cut to hold the cord by which the weight is sustained; a small pan for the priming projects at right angles from the barrel.

The face of the ratchet wheel is graduated with about 50 divisions, beginning from its lowest point, and the numbers ascend at the opposite side to the weight; the mark for good powder is about the 13th degree, and when the explosion forces round this mark to the catch, the powder is known to be of the quality desired; but for the greater precision, the trial is repeated several times, and the mean term taken. The apparatus described is attached to a handle, by which it is held when discharged.

In the powder-provers generally used, a coiled spring acts instead of the weight above-mentioned; and the principal advantage of the new instrument arises from its action being always uniform, while that of the old one varies, on account of the spring losing its elasticity from long continued tension.

M. Regnier invented another *eprouvette*, in which he fitted a small brass cannon (such as the children play with) to one branch of an

ingenious springweighing instrument, fitted with an index, being a piece of cloth or of leather sliding along a wire adjusted parallel to a graduated arch, and a stopper or cap to the muzzle of the piece. Then, as the powder occupies a greater space by its inflammation, it drives back the stopper, and the latter carries with it that branch of the instrument in which its tail is fastened: and that branch cannot remove with respect to the other, which is made to move also by the recoil of the little cannon, without driving before it the small index piece, which, remaining at the place to which it is thus driven, shews the comparative strength of the powder. Here the only friction in the instrument is that of the small cloth index upon its wire, which is exceedingly minute compared with that of teeth and pinions, and on the whole we prefer this, as a portable measure of powder for sportsmen, &c. to any in use.

The most ingenious and accurate eprouvette with which we are acquainted is that employed by Dr. Hutton, in his valuable experiments on gunnery: a description of this instrument may be seen in the 3d vol. of the Doctor's Tracts.

POWDER-ROOM. *s.* (*powder and room.*) The part of a ship in which the gunpowder is kept (*Waller*).

POWDER-CHESTS. *s.* Wooden triangular chests filled with gunpowder, pebble-stones, and such like materials, set on fire when a ship is boarded by an enemy.

POWDERING-TUB. *s.* (*powder and tub.*) 1. The vessel in which meat is salted (*More*). 2. The place in which an infected lecher is physiced to preserve him from putrefaction.

POWDERY. *a.* (*poudreux*, French, from *powder*.) Dusty; friable (*Woodward*).

POWELL (David), a Welch divine and antiquary, born in Denbighshire about 1552, educated at Oxford, where he took his degree of D. D. He died in 1590, and was buried in the church of Ruabon in Denbighshire, of which he was vicar. He published Caradoc's history of Wales with annotations in 1584, and some other works.

POWELL (William Samuel), an English divine, born at Colchester in 1717, and educated at St. John's college, Cambridge. He took the degree of D. D. in 1756, and in 1765 he was elected master of his college. The next year he obtained the archdeaconry of Colchester; and afterwards some valuable livings. He died in 1775, leaving to 20 friends, most of them of the college, 100l. a piece. He is the author of some sermons.

POWELL (George), an English actor who was considered as a rival of Betterton. His propensity to drinking allowed Wilkes, another rival, to surpass him in his walk. He died in 1714. He wrote *Alphonso* king of Naples, and three other pieces; and published as many from the pen of others.

POWER. *s.* (*pouvoir*, French.) 1. Command; authority; dominion; influence of

greatness (*Shakspeare*). 2. Influence; prevalence upon (*Bacon*). 3. Ability; force; reach (*Hooker*). 4. Strength; motive; force (*Locke*). 5. The moving force of an engine (*Wilkins*). 6. Animal strength; natural strength (*Bacon*). 7. Faculty of the mind (*Davies*). 8. Government; right of governing (*Milton*). 9. Sovereign; potentate (*Addison*). 10. One invested with dominion (*Davies*). 11. Divinity (*Dryden*). 12. Host; army; military force (*Knolley*). 13. A large quantity; a great number: as, a power of good things.

POWER (Muscular). See **IRRITABILITY** and **MUSCULAR MOTION**.

POWER (Tonic). See **IRRITABILITY**.

POWER, in mechanics, denotes some force which, being applied to a machine, tends to produce motion; whether it does actually produce it or not. In the former case, it is called a moving power; in the latter, a sustaining power.

POWER is also used in mechanics, for any of the six simple machines, viz. the lever, the balance, the screw, the wheel and axle, the wedge, and the pulley.

POWER OF A GLASS, in optics, is by some used for the distance between the convexity and the solar focus.

POWER, in arithmetic, the produce of a number, or other quantity, arising by multiplying it by itself, any number of times.

Any number is called the first power of itself. If it be multiplied once by itself, the product is the second power, or square; if this be multiplied by the first power again, the product is the third power, or cube; if this be multiplied by the first power again, the product is the fourth power, or biquadratic; and so on; the power being always denominated from the number which exceeds the multiplications by one or unity, which number is called the index or exponent of the power, and is now set at the upper corner towards the right of the given quantity or root, to denote or express the power. Thus,

3 or $3^1 = 3$ is the 1st power of 3,
 3×3 or $3^2 = 9$ is the 2d power of 3,
 $3^2 \times 3$ or $3^3 = 27$ is the 3d power of 3,
 $3^3 \times 3$ or $3^4 = 81$ is the 4th power of 3,
 &c. &c.

Hence, to raise a quantity to a given power or dignity, is the same as to find the product arising from its being multiplied by itself a certain number of times; for example, to raise 2 to the 3d power, is the same thing as to find the factum, or product $8 = 2 \times 2 \times 2$. The operation of raising powers, is called involution.

Powers, of the same degree, are to one another, in the ratio of the roots as manifold as their common exponent contains units: thus, squares are in a duplicate ratio of the roots; cubes in a triplicate ratio; 4th powers in a quadruplicate ratio.—And the powers of proportional quantities are also proportional to one another; so, if $a : b :: c : d$, then, in any powers also, $a^n : b^n :: c^n : d^n$.

P O W E R.

The particular names of the several powers, as introduced by the Arabians, were, square, cube, quadrato-quadratum or biquadrat, sursolid, cube squared, second sursolid, quadrato-quadrato-quadratum, cube of the cube, square of the sursolid, third sursolid, and so on, according to the products of the indices.

And the names given by Diophantus, who is followed by Vieta and Oughtred, are, the side or root, square, cube, quadrato-quadratum, quadrato-cubus, cubo-cubus, quadrato-quadrato-cubus, quadrato-cubo-cubus, cubo-cubo-cubus, &c. according to the sums of the indices.

But the moderns, after Des Cartes, are contented to distinguish most of the powers by the exponents: as 1st, 2d, 3d, 4th, &c.

The characters by which the several powers are denoted, both in the Arabic and Cartesian notation, are as follow:

Arab.	1	R	q	c	bq	s	gc	Bs	tq	bc
Cart.	a^0	a^1	a^2	a^3	a^4	a^5	a^6	a^7	a^8	a^9
	1	2	4	8	16	32	64	128	256	512

Hence, 1st. The powers of any quantity, form a series of geometrical proportionals, and their exponents a series of arithmetical proportionals, in such sort that the addition of the latter answers to the multiplication of the former, and the subtraction of the latter answers to the division of the former, &c.; or in short, that the latter, or exponents, are as the logarithms of the former, or powers.

Thus, $a^2 \times a^3 = a^5$, and $2 + 3 = 5$;

$$4 \times 8 = 32;$$

also $a^5 \div a^3 = a^2$, and $5 - 3 = 2$;

$$32 \div 8 = 4.$$

2d. The 0 power of any quantity, as a^0 , $\frac{1}{a^0} = 1$.

3d. Powers of the same quantity are multiplied, by adding their exponents: Thus,

Mult.	a^3	x^2	y^m	x^m	a^3
by	a^4	a^4	y^m	x^n	a^n
Prod.	a^7	x^6	y^{2m}	x^{m+n}	$a^3 + n$

4th. Powers are divided by subtracting their exponents. Thus,

Div.	a^7	a^6	y^{2m}	x^{m+n}	$a^3 + n$
by	a^3	a^2	y^m	x^m	a^3
Quot.	a^4	a^4	y^m	x^n	a^n

5th. Powers are also considered as negative ones, or having negative exponents, when they denote a divisor, or the denominator of a fraction. So

$$\frac{1}{a^3} = a^{-3}, \text{ and } \frac{2}{a^2} = 2a^{-2}, \text{ and } \frac{a^2}{a^4} = a^2 x^{-4},$$

&c. And hence any quantity may be changed from the denominator to the numerator, or from a divisor to a multiplier, or vice versa, by changing the sign of its exponent; and the whole series of powers proceeds indefinitely

both ways from 1 or the 0 power, positive on the one hand, and negative on the other. Thus,

$$\&c a^{-4} a^{-3} a^{-2} a^{-1} a^0 a^1 a^2 a^3 a^4 \&c,$$

$$\text{or } \&c \frac{1}{a^4} \frac{1}{a^3} \frac{1}{a^2} \frac{1}{a} 1 a a^2 a^3 a^4 \&c.$$

Powers are also denoted with fractional exponents, or even with surd or irrational ones; and then the numerator denotes the power raised to, and the denominator the exponent of some root to be extracted. Thus,

$$\sqrt[2]{a} = a^{\frac{1}{2}}, \text{ and } \sqrt[3]{a^3} = a^1, \text{ and } \sqrt[2]{a^2} = a^1, \&c.$$

And these are sometimes called imperfect powers, or surds.

When the quantity to be raised to any power is positive, all its powers must be positive. And when the radical quantity is negative, yet all its even powers must be positive: because $- \times -$ gives $+$: the odd powers only being negative, or when their exponents are odd numbers. Thus, the powers of $-a$,

$$\text{are } +1, -a, +a^2, -a^3, +a^4, -a^5, +a^6, \&c.$$

where the even powers a^2, a^4, a^6 are positive, and the odd powers a, a^3, a^5 are negative.

Hence, if a power have a negative sign, no even root of it can be assigned; since no quantity multiplied by itself an even number of times, can give a negative product. Thus $\sqrt{-a^2}$, or the square or 2d root of $-a^2$, cannot be assigned; and is called an impossible root, or an imaginary quantity.—Every power has as many roots, real and imaginary, as there are units in the exponent.

M. De la Hire gives a very odd property common to all powers. M. Carre had observed with regard to the number 6, that all the natural cubic numbers, 8, 27, 64, 125, having their roots less than 6, being divided by 6, the remainder of the division is the root itself; and if we go farther, 216, the cube of 6, being divided by 6, leaves no remainder; but the divisor 6 is itself the root. Again, 343, the cube of 7, being divided by 6, leaves 1; which added to the divisor 6, makes the root 7, &c. M. De la Hire, on considering this, has found that all numbers, raised to any power whatever, have divisors, which have the same effect with regard to them, that 6 has with regard to cubic numbers. For finding these divisors, he discovered the following general rule, viz. if the exponent of the power of a number be even, i. e. if the number be raised to the 2d, 4th, 6th, &c. power, it must be divided by 2; the remainder of the division, when there is any, added to 2, or to a multiple of 2, gives the root of this number, corresponding to its power, i. e. the 2d, 6th, &c. root.

But if the exponent of the power be an uneven number, i. e. if the number be raised to the 3d, 5th, 7th, &c. power; the double of this exponent will be the divisor, which has the property above-mentioned. Thus is it found in 6, the double of 3, the exponent of the power of the cubes: so also 10, the double of 5, is the divisor of all 5th powers; &c.

Any power of the natural numbers 1, 2, 3, 4, 5, 6, &c. as the *n*th power, has as many orders of differences as there are units in the common exponent of all the numbers; and the last of those differences is a constant quantity, and equal to the continual product $1 \times 2 \times 3 \times 4 \times \dots \times n$, continued till the last factor, or the number of factors, be *n*, the exponent of the powers.

For more on this curious subject, see the works of Fermat, Ozanam, Hutton's *Mon-tucla*, Gauss, Barlow, &c.

POWER OF AN HYPERBOLA, in conic sections, the square of the fourth part of the conjugate axis.

POWERABLE. *a.* (from *power*.) Capable of performing any thing; not used (*Camden*).

POWERFUL. *a.* (*power* and *full*.) 1. Invested with command or authority; potent. 2. Forcible; mighty (*Milton*). 3. Efficacious; as, a *powerful* medicine.

POWERFULLY. *ad.* Potently; mightily; efficaciously; forcibly (*Tillotson*).

POWERFULNESS. *s.* (from *powerful*.) Power; efficacy; might; force (*Hakewill*).

POWERLESS. *a.* (from *power*.) Weak; impotent (*Shakspeare*).

POX, in medicine. See *LUES VENEREA*.

POX (Small). See *INOCULATION*, &c.

POY. *s.* (*appoy*, Spanish; *appuy*, *poids*, Fr.) A ropedancer's pole.

TO POZE. *v. a.* To puzzle. See *POSE* and *APPOSE* (*Glanville*).

POZZOLANA, **PONZZOLANA**, **PONZ-ZOLANO**. See *PUTEOLANA*.

PRACTICABLE. *a.* (*practicable*, Fr.) 1. Performable; feasible; capable to be practised (*L'Estrange*). 2. Assailable; fit to be assailed; as, a *practicable* breach.

PRACTICABLENESS. *s.* (from *practicable*.) Possibility to be performed.

PRACTICABLY. *ad.* (from *practicable*.) In such a manner as may be performed (*Rogers*).

PRACTICAL. *a.* (*practicus*, Lat.) Relating to action; not merely speculative (*Tillotson*).

PRACTICALLY. *ad.* (from *practical*.) 1. In relation to action. 2. By practice; in real fact (*Houel*).

PRACTICALNESS. *s.* (from *practical*.) The quality of being practical.

PRACTICE. *s.* (*πρaxis*; *pratique*, Fr.)

1. The habit of doing any thing. 2. Use; customary use (*Tate*). 3. Dexterity acquired by habit (*Shakspeare*). 4. Actual performance, distinguished from theory (*South*). 5. Method or art of doing any thing. 6. Medical treatment of diseases (*Shakspeare*). 7. Exercise of any profession (*Blackmore*). 8. (from *πραξ*, Saxon, cunning.) Wicked stratagem; bad artifice: not in use (*Sidney*).

PRACTICE, a rule in arithmetic. See *ARITHMETIC*.

PRACTIC. PRACTICAL. *a.* (*πρaxis*; *practicus*, Latin; *pratique*, French.) 1. Relating to action; not merely theoretical (*Denham*). 2. Sly; artful: not in use (*Spenser*).

TO PRACTISE. *v. a.* (*πρaxis*; *pratiquer*, French.) 1. To do habitually (*Psalms*). 2. To do; not merely to profess: as, to practise *law* or *physic*. 3. To use in order to habit and dexterity.

TO PRACTISE. *v. n.* 1. To form a habit of acting in any manner (*Waller*). 2. To transact; to negotiate secretly (*Addison*). 3. To try artifices (*Granville*). 4. To use bad arts or stratagemis (*Shakspeare*). 5. To use medical methods (*Temple*). 6. To exercise any profession.

PRACTISANT. *s.* (from *practise*.) An agent (*Shakspeare*).

PRACTISER. *s.* (from *practise*.) 1. One that practises any thing; one that does any thing habitually (*South*). 2. One who prescribes medical treatment (*Shakspeare*).

PRACTITIONER. *s.* (from *practise*.) 1. He who is engaged in the actual exercise of any art (*Arbutnot*). 2. One who uses any sly or dangerous arts (*Whitgift*). 3. One who does any thing habitually (*South*).

PRADES, a small handsome town of France, in the department of Eastern Pyrenees, seated on the river Tet, in a fine plain, in the middle of mountains, 22 miles S.E. of Montlouis. Lon. 2. 35 E. Lat. 42. 26 N.

PRAECIPITATE RED. See *HYDRARGYRUS NITRATUS RUBER*.

PRAECIPITATE WHITE. See *CALX HYDRARGYRI ALBA*.

PRAECOGNITA. *s.* (Latin.) Things previously known in order to understand something else (*Locke*).

PRAECORDIA. (from *præ*, before, and *καρδια*, the heart.) The fore part of the region of the thorax.

PRÆMORSE, in botany. Bitten off. Præmorse root; not tapering, but ending blunt, and thus appearing as if it were bitten off short at the end, as in scabiosa, plantago, valeriana. Præmorse leaf: ending very obtusely, with unequal notches.—Præmorse corol: as in althæa.

PRÆMUNIRE, is a punishment inflicted upon him who denies the king's supremacy the second time; upon him who affirms the authority of the Pope, or refuses to take the oath of supremacy; upon such as are seditious talkers of the inheritance of the crown; and upon such as affirm that there is any obligation by any oath, covenant, or engagement whatsoever, to endeavour a change of government either in church or state; or that both or either house of Parliament have or hath a legislative power without the king, &c. The judgment in præmunire at the suit of the king, against the defendant being in prison, is, that he shall be out of the king's protection; that his lands and tenements, goods and chattels, shall be forfeited to the king; and that his body shall remain in prison at the king's pleasure; but if the defendant be condemned upon his default of not appearing, whether at the suit of the king or party, the same judgment shall be given as to the being out of the king's protection and the forfeiture; but instead of

the clause that the body shall remain in prison, there shall be an award of a *capiatu*r or arrest. Upon an indictment of a *præmunire*, a peer of the realm shall not be tried by his peers.

PRÆNESTE, a town of Latium, about 21 miles from Rome, built by Telegonus, son of Ulysses and Circe, or according to others, by Cæcilius, the son of Vulcan. There was a celebrated temple of Fortune there, as also an oracle, which was long in great repute. This is now Palestrina.

PRÆPUCE. (*preputium*.) The membranous cutaneous fold that covers the glans penis and clitoris.

PRÆTOR, one of the chief magistrates at Rome. The office of prætor was first instituted A. U. C. 388, by the senators, and received its name a *præundo*. Only one was originally elected, and another A. U. C. 501. Their number gradually increased to 64, and after this their numbers fluctuated, being sometimes 18, 16, or 12, till in the decline of the empire their dignity decreased, and their numbers were reduced to three. In his public capacity the prætor administered justice, protected the rights of widows and orphans, presided at the celebration of public festivals, and in the absence of the consul assembled or prorogued the senate as he pleased. There were also other duties annexed to his office. When the year of their prætorship was elapsed, they were called *proprætors*, if they still continued at the head of their province.

PRAGMATICAL. **PRAGMATIC**. *a.* (*πραγματικα*.) Meddling; impertinently busy; assuming business without leave or invitation.

PRAGMATIC SANCTION, in the civil law, is defined by Hottoman to be a rescript or answer of the sovereign, delivered by advice of his council, to some college, order, or body of people, upon consulting him on some case of their community. The like answer given to any particular person is called simply rescript. The term pragmatic sanction is chiefly applied to a settlement of Charles VI. emperor of Germany, who, in the year 1722, having no sons, settled his hereditary dominions on his eldest daughter the archduchess Maria Theresa, which was confirmed by the diet of the empire, and guaranteed by Great Britain, France, the states-general, and most of the powers in Europe. The word pragmatic is derived from the Greek *πραγμα*, *negotium*, business. It is sometimes also called absolutely *pragmatic*, το *πραγματικον*.

PRAGMATICALLY. *ad.* (from *pragmatical*.) Meddlingly; impertinently.

PRAGMATICALNESS. *s.* (from *pragmatical*.) The quality of intermeddling without right or call.

PRAGUE, a fortified city, capital of Bohemia, and lately an archiepiscopal see. It comprehends four towns, the Old, New, and Little Town, and Radshin. It is 15 miles in circumference, built upon seven hills; has about 100 churches and as many palaces; and contains 80,000 inhabitants. The Muldau runs through the city, separating the Old

Town from the New, and over it is a bridge of 18 arches, with a strong tower at each end. The Old Town is very populous; the houses are high and the streets narrow. In this part is the old palace, where the ancient kings resided; but the finest ornament is the university, frequented by a great number of students. Here also is a magnificent college, formerly belonging to the jesuits, and the Jews have nine synagogues. The New Town contains fine structures, handsome gardens, and large streets; also an arsenal, and a secular foundation, whose abbess was a princess of the empire. The Little Town, which is the most ancient part of Prague, has broad streets, and is very populous. Radshin once belonged to the Little Town, but in 1756 it was made the fourth town of Prague: its principal buildings are the royal palace, in which is a hall, 100 paces long and 40 broad, without any pillar to support the roof; the cathedral of St. Veit, containing the burial-place of the kings and many relics; the chapel of Our Lady of Loretto; the magnificent archiepiscopal palace; and the large palace of Tschernin. Prague has suffered frequent devastations by war, which were however soon repaired. The White mountain, without the gate of Strahow, is celebrated for the victory, in 1620, gained by the Austrians over Frederic V. of the Palatinate, whom the Bohemians had chosen for their king. In 1631, Prague was taken by the Saxons; and by the Swedes in 1648. It was taken by storm by the French in 1741; but they were obliged to leave it in 1742. In 1744, it was taken by the king of Prussia; but he was obliged to abandon it in the same year. It was besieged by the king of Prussia, in 1757, after a great victory, obtained near the city, over the Austrians; but being defeated some time after, he was obliged to raise the siege. It is 75 miles S.E. of Dresden, and 235 N.W. of Vienna. Lon. 14. 42 E. Lat. 50. 6 N.

PRAISE. *s.* (*prijz*, Dutch.) 1. Renown; commendation; fame; honour; celebrity (*Dryden*). 2. Glorification; tribute of gratitude; laud (*Milton*). 3. Ground or reason of praise (*Dryden*).

To PRAISE. *v. a.* (*prijzen*, Dutch.) 1. To commend; to applaud; to celebrate (*Milton*). 2. To glorify in worship (*Psalms*).

PRAISEFUL. *a.* (*praise* and *full*.) Laudable; commendable; not in use (*Chapman*).

PRAISER. *s.* (from *praise*.) One who praises; an applauder; a commander (*Sid*).

PRAISEWORTHY. *a.* (*praise* and *worthy*.) Commendable; deserving praise (*Ben Jonson*).

PRAM, or **PRAME**, a kind of lighter used in Holland and the ports in the Baltic Sea, to carry the cargo of a merchant ship alongside, in order to lade it, or to bring it to the shore to be lodged in warehouses. The same term is in use in military affairs, for a kind of floating battery, being a flat-bottomed vessel, which draws little water, mounts several guns, and is exceedingly useful in transporting troops over the immense lakes in North America.

To PRANCE. *v. n.* (*pronken*, Dutch.) 1. To spring and bound in high mettle (*Wotton*). 2. To ride gallantly and ostentatiously (*Add.*). 3. To move in a warlike or showy manner (*Swift*).

To PRANK. *v. a.* (*pronken*, Dutch.) To decorate; to dress or adjust to ostentation (*Milton*).

PRANK. *s.* A frolic; a wild flight; a ludicrous trick; a mischievous act (*Raleigh*).

PRASE, in mineralogy, a peculiar species of quartz consisting of this substance intimately intermixed with actinolite; found in mass at Brutenbrun in Saxony, of a leek-green colour, with a lustre glistening between resinous and vitreous. See QUARTZUM.

PRASIUM. Hedge-nettle. In botany, a genus of the class didynamia, order gymnospermia. Berries four; one-seeded. Two species; natives of Sicily; shrubby stalks, and leaves like those of baum.

To PRATE. *v. n.* (*praten*, Dutch.) To talk carelessly and without weight; to chatter; to tattle; to be loquacious (*Cleaveland*).

PRATE. *s.* (from the verb.) Tattle; slight talk; unmeaning loquacity (*Denham*).

PRA'TER. *s.* (from *prate*.) An idle talker; a chatterer (*Southern*).

PRATINAS, a Greek poet of Phlius, contemporary with Æschylus. He was the first among the Greeks who composed satires, which were represented as farces (*Paus.*).

PRATINCOLE, in ornithology. See GLAREOLA.

PRA'TINGLY. *ad.* (from *prate*.) With tittle-tattle; with loquacity.

PRA'TIQUE. *s.* (Fr. *prattica*, Italian.) A licence for the master of a ship to traffic in the ports of Italy, upon a certificate that the place from whence he came, is not annoyed with any infectious disease (*Bailey*).

PRATT (Charles), earl Camden, was born in 1713. By dint of perseverance he overcame every obstacle, and rose to the first honours of the profession of the law. In 1759 he was appointed attorney-general; and in 1762 chief justice of the court of common-pleas. In this situation he conducted himself with great dignity, and a sacred regard to the rights and privileges of the British subject; particularly in the affair of Mr. Wilkes in 1763. The corporation of London, on this occasion, presented him with the freedom of the city in a gold box, and caused his picture to be put up in Guildhall, with a suitable inscription. Other cities followed the example of the metropolis, in honouring the integrity of this virtuous judge. In 1765 he was created a peer, and soon after appointed lord chancellor, in which capacity he declared the opinion of the whole court against the validity of general warrants. In 1770 he was removed from his place for opposing the measures of administration with respect to America. In 1782 he was appointed president of the council, which station he resigned next year, but shortly after resumed it, and held it till his death in 1794.

To PRATTLE. *v. n.* (diminutive of *prate*.)

To talk lightly; to chatter; to be trivially loquacious (*Locke*).

PRAT'TLE. *s.* (from the verb.) Empty talk; trifling loquacity (*Shakspeare*).

PRATTLER. *s.* (from *prattle*.) A trifling talker; a chatterer (*Herbert*).

PRA'VITY. *s.* (*pravitas*, Lat.) Corruption; badness; malignity (*South*).

PRAUSNITZ, a town and castle of Silesia, in the lordship of Trachenberg. It has a fine church, containing the tombs of the counts of Hatzfeld, and is seven miles S. of Trachenberg.

PRAXAGORAS, an Athenian writer, who published an history of the kings of his own country. He was then only 19 years old, and three years after that, he wrote the life of Constantine the Great. He had also written the life of Alexander, all now lost.

PRAXIDACE, a goddess among the Greeks, who presided over the execution of enterprizes, and who punished all evil actions.

PRAXITELES, a very famous Greek sculptor, who lived 330 years before Christ, at the time of the reign of Alexander the Great. All the ancient writers mention his statues with a high commendation, especially a Venus executed by him for the city of Cnidos, which was so admirable a piece, that king Nicomedes offered to release the inhabitants from their tribute as the purchase of it; but they refused to part with it. The inhabitants of the isle of Cos requested of Praxiteles a statue of Venus; and in consequence of this application the artist gave them their choice of two; one of which represented the goddess entirely naked, and the other covered with drapery. Both of these were of exquisite workmanship; although the former was esteemed the most beautiful, nevertheless the inhabitants of Cos had the wisdom to give the preference to the latter, from a conviction that no motive whatever could justify their introducing into their city any indecent statues or paintings, which are so likely to inflame the passions of young people, and lead them to immorality and vice. What a reproach will this be to many Christians!—He was one of the gallants of Phryne the celebrated courtesan.

To PRAY. *v. n.* (*prier*, French; *pregare*, Italian.) 1. To make petition to heaven (*Taylor*). 2. To entreat; to act submissively (*Dryden*). 3. I PRAY, is a slightly ceremonious form of introducing a question (*Bentley*).

To PRAY. *v. a.* 1. To supplicate; to implore; to address with submissive petitions (*Milton*). 2. To ask for as a supplicant (*Ayl.*). 3. To entreat in ceremony or form (*Ben Jonson*).

PRA'YER. *s.* (*prire*, French.) 1. Petition to heaven (*Law*). 2. Mode of petition (*White*). 3. Practice of supplication (*Shakspeare*). 4. Single formulæ of petition (*Taylor*). 5. Entreaty; submissive importunity (*Stillington*).

PRAYER, a solemn address to God, which, when it is of any considerable length, consists of adoration, confession, supplication, intercession, and thanksgiving.

P R A Y E R.

By adoration we express our sense of God's infinite perfections, his power, wisdom, goodness, and mercy; and acknowledge that our constant dependence is upon him by whom the universe was created and has been hitherto preserved. By confession is meant our acknowledgment of our manifold transgressions of the divine laws, and our consequent unworthiness of all the good things which we enjoy at present or expect to be conferred upon us hereafter. In supplication we intreat our omnipotent Creator and merciful judge not to deal with us after our iniquities, but to pardon our transgressions, and by his grace to enable us to live henceforth righteously, soberly, and godly, in this present world; and by Christians this intreaty is always made in the name and through the mediation of Jesus Christ, because to them it is known that there is none other name under heaven given unto men whereby they may be saved. To these supplications for mercy we may likewise add our prayers for the necessities of life; because if we seek first the kingdom of God and his righteousness, we are assured that such things shall be added unto us. Intercession signifies those petitions which we offer up for others, for friends, for enemies, for all men, especially for our lawful governors whether supreme or subordinate. And thanksgiving is the expression of our gratitude to God, the giver of every good and perfect gift, for all the benefits enjoyed by us and others, for the means of grace, and for the hope of glory. Such are the component parts of a regular and solemn prayer, adapted either for the church or for the closet. But an ejaculation to God, conceived on any emergency, is likewise a prayer, whether it be uttered by the voice or suffered to remain a mere affection of the mind; because the Being to whom it is addressed discerneth the thoughts of the heart.

That prayer is a duty which all men ought to perform with humility and reverence, has been generally acknowledged as well by the untaught barbarian as by the enlightened Christian.

Nothing so forcibly restrains from ill as the remembrance of a recent address to heaven for protection and assurance. After having petitioned for power to resist temptation, there is so great an incongruity in not continuing the struggle, that we blush at the thought, and persevere lest we lose all reverence for ourselves. After fervently devoting our souls to God, we start with horror at immediate apostacy: every act of deliberate wickedness is then complicated with hypocrisy and ingratitude.

The following objection has been often and seriously alleged against prayer: "If it be most agreeable to perfect wisdom and justice that we should receive what we desire, God, as perfectly wise and just, will give it to us without asking; if it be not agreeable to these attributes of his nature, our entreaties cannot move him to give it us, and it were impious to expect they should." In fewer words, thus: "If what we request be fit for us, we shall have it

without praying; if it be not fit for us, we cannot obtain it by praying." This objection admits but of one answer, namely, that it may be agreeable to perfect wisdom to grant that to our prayers, which it would not have been agreeable to the same wisdom to have given us without praying for. But what virtue, you will ask, is there in prayer, which should make a favour consistent with wisdom, which would not have been so without it? To this question, which contains the whole difficulty attending the subject, the following possibilities are offered in reply.

1. A favour granted to prayer may be more apt, on that very account, to produce good effects upon the person obliged. It may hold in the divine bounty, what experience has raised into a proverb in the collation of human benefits, that which is obtained without asking, is oftentimes received without gratitude.

2. It may be consistent with the wisdom of the Deity to withhold his favours till they be asked for, as an expedient to encourage devotion in his rational creation, in order thereby to keep up and circulate a knowledge and sense of their dependency upon him.

3. Prayer has a natural tendency to amend the petitioner himself, and thus to bring him within the rules which the wisdom of the Deity has prescribed to the dispensation of his favours. If these, or any other assignable suppositions, serve to remove the apparent repugnancy between the success of prayer and the character of the Deity, it is enough; for the question with the petitioner is not from which, out of many motives, God may grant his petition, or in what particular manner he is moved by the supplications of his creatures; but whether it be consistent with his nature to be moved at all, and whether there be any conceivable motives which may dispose the divine will to grant the petitioner what he wants, in consequence of his praying for it. (*Paley's Mor. Philosophy*, vol. 2).

Nearly of like import is the language of William Law. "If men (says he) would consider prayer not only as it is an invocation of God, but also as it is an exercise of holy thoughts, as it is an endeavour to feel and to be affected with the great truths of religion, they would soon see that though God is so good as not to need much calling upon; yet that man is so weak as to need much assistance, and to be under a constant necessity of that help, and light, and improvement, which arises from praying much.

"If God does not give us at our first asking; if he only gives to those who are importunate; it is not because our prayers make any change in God, but because our importunity has made a change in ourselves; it has altered our hearts, and rendered us proper objects of God's gifts and graces. When, therefore, we would know how much we ought to pray, we must consider how much our hearts want to be altered, and remember that the great object of prayer is to work upon ourselves; it is not to move and affect God, but it is to move and affect our

own hearts, and fill them with such tempers as God delights to reward." (*Law on Perfection*, chap. 12).

PRA'YERBOOK. *s.* (*prayer and book*.) Book of public or private devotions (*Shakespeare*).

PRE. (*præ*, Latin.) A particle which marks priority of time or rank.

TO PREACH. *v. n.* (*prædico*, Latin; *precher*, French.) To pronounce a public discourse upon sacred subjects (*Decay of Piety*).

TO PREACH. *v. a.* 1. To proclaim or publish in religious orations (*Acts*). 2. To inculcate publicly; to teach with earnestness (*Dryden*).

PREACH. *s.* (*presche*, French.) A discourse; a religious oration: not in use (*Hooker*).

PREA'CHER. *s.* (*prescheur*, French, from *preach*.) 1. One who discourses publicly upon religious subjects (*Crashaw*). 2. One who inculcates any thing with earnestness and vehemence (*Swift*).

PREACHING. (from the Hebrew *parasch*, *exposuit*, "he expounded.") The art of explaining, and enforcing religious topics orally from the pulpit.

Here it is obvious, the dignity and sanctity of the place, and the importance of the subject, require the preacher to exert the utmost powers of his voice to produce a pronunciation that is perfectly distinct and harmonious, and that he observe a deportment and action which is expressive and graceful. No man, therefore, who is destitute of a voice should ascend the pulpit, and there act the part of a pantomime before his audience. The preacher should not, however, roar like a common crier, and rend the ear with the voice of thunder; for such kind of declamation is not only without meaning and without persuasion, but highly incongruous with the meek and gentle expressions of the gospel. He should likewise take particular care to avoid a monotony; his voice should rise from the beginning, as it were by degrees, and its greatest strength should be exerted in the application. Each inflection of the voice should be adapted to the phrase, and to the meaning of the words; and each remarkable expression should have its peculiar inflexion. The dogmatic requires a plain uniform tone of voice only; and the menaces of the gospel demand a greater force than do its promises and rewards: but the latter should not be pronounced in the soft tone of a flute, nor the former with the loud sound of a trumpet. The voice should still retain its natural tone in all its various inflexions. Happy is that preacher to whom nature has given a voice that is at once strong, flexible, and harmonious.

An air of complacency and benevolence, as well as devotion, should be constantly visible in the countenance of the preacher. But every appearance of affectation must be carefully avoided; for nothing is so disgusting to an audience as even the semblance of dissimulation. Eyes constantly rolling, turned towards heaven, and streaming with tears, rather

denote a hypocrite than a man possessed of the real spirit of religion, and that feels the true import of what he preaches. An air of affected devotion infallibly destroys the efficacy of all that the preacher can say, however just and important it may be. On the other hand, he must avoid every appearance of mirth or raillery, or of that cold and unfeeling manner which is so apt to freeze the hearts of his hearers.

The body should be in general erect, and in a natural and easy attitude. The perpetual movement, or contortion of the body, has a ridiculous effect in the pulpit, and makes the figure of a preacher and a harlequin much too similar. But, on the other hand, he should not remain constantly upright and motionless, like a speaking statue.

The motions of the hands give a strong expression to a discourse; but they should be constantly decent, grave, noble, and expressive. The preacher who is incessantly in action, who is perpetually clapping his hands, or who menaces with a clenched fist, or counts his arguments on his fingers, will only excite mirth among his auditory. In a word, declamation is an art that the sacred orator should study with the utmost assiduity. The design of a sermon is to convince, to affect, and to persuade. The voice, the countenance, and the action, which are to produce this triple effect, are therefore the objects to which the preacher should particularly apply himself.

Nothing is more incompatible with the business of a preacher than a dead and frigid manner. "A statue hung round with moral sentences," says Dr. Watts, "or a marble pillar with divine truths inscribed upon it, may preach coldly to the understanding, while devotion freezes at the heart. But the prophets and apostles were *burning and shining lights*; they were all taught by inspiration to make the words of truth glitter like sun-beams, and to operate like a hammer, and a fire, and a two-edged sword. The movements of sacred passion may be the ridicule of an age which pretends to nothing but calm reasoning. Life and zeal in the ministry of the word may be despised by men of lukewarm and dying religion. Fervency of spirit in the service of the Lord may become the scoff and jest of the critic and the profane: but this very life and zeal, this sacred fervency, shall still remain one bright character of a christian preacher, till the names of Paul and Apollos perish from the church; and that is, till this Bible and these heavens are no more."

It will be observed that we have said nothing here respecting the *reading* of sermons. Our reason is obvious: reading is not preaching, but bears about the same relation to it that leaning upon crutches does to walking. The practice, prevalent as it is, has been forbidden by the highest authority; in proof of which we here insert the following curious document. It is an extract from the statute book of the university of Cambridge, page 300, Carol. II. Rex.

" Vice-chancellor and gentlemen,

" Whereas his majesty is informed that the practice of reading sermons is generally taken up by the preachers before the university, and therefore continues even before himself; his majesty hath commanded me to signify to you his pleasure, that the said practice, which took its beginning from the disorders of the late times; be wholly laid aside; and that the said preachers deliver their sermons, both in Latin and English, by memory, without book; as being a way of preaching which his majesty judgeth most agreeable to the use of foreign churches, to the custom of the university heretofore, and to the nature of that holy exercise. And, that his majesty's commands in these premises may be duly regarded and observed, his further pleasure is, that the names of all such ecclesiastical persons as shall continue the present supine and slothful way of preaching be, from time to time, signified to me, by the vice-chancellor for the time being, on pain of his majesty's displeasure.

" MONMOUTH."

" Oct. 8th, 1674."

PREA'CHMENT. *s.* (from *preach*.) A sermon mentioned in contempt; a discourse affectedly solemn (*L'Estrange*).

PREAMBLE. *s.* (*preambule*, French.) Something previous; introduction; preface (*Hooker*).

PREAMBULARY. **PREA'MBULOUS.** *a.* (from *preamble*.) Previous (*Brown*).

PREAPPREHENSION. *s.* (*pre* and *apprehend*.) An opinion formed before examination (*Brown*).

PREASE. *s.* Press; crowd: obsolete (*Spenser*).

PRES'ING. *part. a.* Crowding (*Spenser*).

PREBEND, the maintenance a prebendary receives out of the estate of a cathedral or collegiate church. Prebends are distinguished into simple and dignitary: a simple prebend has no more than the revenue for its support: but a prebend with dignity; has always a jurisdiction annexed to it.

PREBENDARY, an ecclesiastic who enjoys a prebend. The difference between a prebendary and a canon is, that the former receives his prebend in consideration of his officiating in the church; but the latter merely by his being received into the cathedral or college.

PREBENDARY (Golden), of Hereford, called also *prebendarius episcopus*, is one of the twenty-eight minor prebendaries, who has, *ex officio*, the first canon's place that falls. He was anciently confessor of the bishop and cathedral, and had the offerings at the altar; on which account he was called the golden prebendary.

PRECA'RIOUS. *a.* (*precarius*, Latin.) Dependent; uncertain, because depending on the will of another; held by courtesy (*Addison*).

PRECA'RIOUSLY. *ad.* Uncertainly by dependence; dependently.

PRECA'RIOUSNESS. *s.* (from *precarius*.) Uncertainty; dependence on others (*Sharp*).

PRECAUTION. *s.* (*precaution*, Fr.) Preservative caution; preventive measures (*Addison*).

To PRECAUTION. *v. a.* (*precautioner*, Fr.) To warn beforehand (*Locke*).

PRECEDA'NEOUS. *a.* Previous; antecedent.

To PRECE'DE. *v. a.* (*præcedo*, Latin.) 1. To go before in order of time (*Dryden*). 2. To go before according to the adjustment of rank.

PRECE'DENCE. **PRECE'DENCY.** *s.* (from *præcedo*, Latin.) 1. The act or state of going before; priority. 2. Something going before; something past: not used (*Shakspeare*). 3. Adjustment of place (*Hale*). 4. The foremost in ceremony (*Dryden*). 5. Superiority (*Loc.*).

PRECEDENCE, or **PRECEDENCY**, a place of honour to which a person is entitled: this is either of courtesy or of right. The former is that which is due to age, estate, &c. which is regulated by custom and civility: the latter is settled by authority, and when broken in upon gives an action at law. The order of precedence, for all ranks, as established at the Herald's college, is shown in our article **HERALDRY**.

PRECEDENT. *a.* (*precedent*, French; *præcedens*, Latin.) Former; going before (*South*).

PRE'CEDENT. *s.* Any thing that is a rule or example to future times; any thing done before of the same kind (*Granville*).

PRECEDENTLY. *ad.* (from *precedent*, adj.) Beforehand.

PRECENTOR. *s.* (*præcentor*, Lat. *præcenteur*, French.) He that leads the choir (*Hammond*).

PRE'CEPT. *s.* (*præceptum*, Latin.) A rule authoritatively given; a mandate (*Dryden*).

PRECEPTIAL. *a.* (from *precept*.) Consisting of precepts: not in use (*Shakspeare*).

PRECEPTIVE. *a.* (*præceptivas*, Latin.) Containing precepts; giving precepts (*L'Estrange*).

PRECEPTOR. *s.* (*præceptor*, Latin.) A teacher; a tutor (*Blackmore*).

PRECESSION. *s.* (*præcessus*, Latin.) The act of going before.

PRECESSION OF THE EQUINOXES. The most obvious of all the celestial motions is the diurnal revolution of the stary heavens. The whole appears to turn round an imaginary axis, which passes through two opposite points of the heavens, called the poles. One of these is in our sight, being very near the star in the tail of the little bear. The great circle which is equidistant from both poles divides the heavens into the northern and southern hemispheres, which are equal. It is called the equator, and it cuts the horizon in the east and west points, and every star in it is 12 sideral hours above and as many below the horizon, in each revolution.

The sun's motions determine the length of day

PRECESSION.

and night, and the vicissitudes of the seasons. By a long series of observations, the shepherds of Asia were able to mark out the sun's path in the heavens; he being always in the opposite point to that which comes to the meridian at midnight, with equal but opposite declination. Thus they could tell the stars among which the sun then was, although they could not see them. They discovered that his path was a great circle of the heavens, afterward called the ecliptic; which cuts the equator in two opposite points, dividing it, and being divided by it, into two equal parts. They further observed, that when the sun was in either of these points of intersection, his circle of diurnal revolution coincided with the equator, and therefore the days and nights were equal. Hence the equator came to be called the equinoctial line, and the points in which it cuts the ecliptic were called the equinoctial points, and the sun was then said to be in the equinoxes. One of these was called the vernal and the other the autumnal equinox.

It was evidently an important problem in practical astronomy, to determine the exact moment of the sun's occupying these stations; for it was natural to compute the course of the year from that moment. Accordingly, this has been the leading problem in the astronomy of all nations. It is susceptible of considerable precision, without any apparatus of instruments. It is only necessary to observe the sun's declination on the noon of two or three days before and after the equinoctial day. On two consecutive days of this number, his declination must have changed from north to south, or from south to north. If his declination on one day was observed to be $21'$ north, and on the next $5'$ south, it follows that his declination was nothing, or that he was in the equinoctial point about 23 minutes after 7 in the morning of the second day. Knowing the precise moments, and knowing the rate of the sun's motion in the ecliptic, it is easy to ascertain the precise point of the ecliptic in which the equator intersected it.

By a series of such observations made at Alexandria, between the years 161 and 127 before Christ, Hipparchus, the father of our astronomy, found that the point of the autumnal equinox was about six degrees to the eastward of the star called spica virginis. Eager to determine every thing by multiplied observations, he ransacked all the Chaldaean, Egyptian, and other records, to which his travels could procure him access, for observations of the same kind; but he does not mention his having found any. He found, however, some observations of Aristillus and Timochares made about 150 years before. From these it appeared evident that the point of the autumnal equinox was then about eight degrees east of the same star. He discusses these observations with great sagacity and rigour; and, on their authority, he asserts that the equinoctial points are not fixed in the heavens, but move to the westward about a degree in 75 years, or somewhat less.

This motion is called the precession of the equinoxes, because by it the time and place of the sun's equinoctial station precedes the usual calculations; it is fully confirmed by all subsequent observations. In 1750 the autumnal equinox was observed to be $20^{\circ} 21'$ westward of spica virginis. Supposing the motion to have been uniform during this period of ages, it follows that the annual precession is about $50\frac{1}{2}''$; that is, if the celestial

equator cut the ecliptic in a particular point on any day of this year it will on the same day of the following year cut it in a point $50\frac{1}{2}''$ to the west of it, and the sun will come to the equinox $20' 23''$ before he has completed his round of the heavens. Thus the equinoctial or tropical year, or true year of seasons, is so much shorter than the revolution of the sun or the sidereal year.

It is this discovery that has chiefly immortalized the name of Hipparchus, though it must be acknowledged that all his astronomical researches have been conducted with the same sagacity and intelligence. It was natural therefore for him to value himself highly for the discovery. It must be acknowledged to be one of the most singular that has been made, that the revolution of the whole heavens should not be stable, but its axis continually changing. For it must be observed, that since the equator changes its position, and the equator is only an imaginary circle, equidistant from the two poles or extremities of the axis; these poles and this axis must equally change their positions. The equinoctial points make a complete revolution in about 25745 years, the equator being all the while inclined to the ecliptic in nearly the same angle. Therefore the poles of this diurnal revolution must describe a circle round the poles of the ecliptic at the distance of about $23\frac{1}{2}$ degrees in 25745 years; and in the time of Timochares the north pole of the heavens must have been 30 degrees eastward of where it now is.

Hipparchus has been accused of plagiarism and insincerity in this matter. It is now very certain that the precession of the equinoxes was known to the astronomers of India many ages before the time of Hipparchus. It appears also that the Chaldeans had a pretty accurate knowledge of the year of seasons. From their saros we deduce their measure of this year to be 365 days 5 hours 49 minutes and 11 seconds, exceeding the truth only by $26''$, and much more exact than the year of Hipparchus. They had also a sidereal year of 365 days 6 hours 11 minutes. Now what could occasion an attention to two years, if they did not suppose the equinoxes moveable? the Egyptians also had a knowledge of something equivalent to this; for they had discovered that the dog-star was no longer the faithful forewarner of the overflowing of the Nile, and they combined him with the star Fomalhaut in their mystical kalendar. This knowledge is also involved in the precepts of the Chinese astronomy, of much older date than the time of Hipparchus.

But all these acknowledged facts are not sufficient for depriving Hipparchus of the honour of the discovery, or fixing on him the charge of plagiarism. This motion was a thing unknown to the astronomers of the Alexandrian school, and it was pointed out to them by Hipparchus in the way in which he ascertained every other position in astronomy, namely, as the mathematical result of actual observations, and not as a thing deducible from any opinions on other subjects related to it. We see him, on all other occasions, eager to confirm his own observations, and his deductions from them, by every thing he could pick up from other astronomers; and he even adduced the above-mentioned practice of the Egyptians in corroboration of his doctrine. It is more than probable then that he did not know any thing more. Had he known the Indian precession of $54''$ annually, he had no temptation whatever to withhold him from using it in preference to one which he ac-

PRECESSION.

knowledge to be inaccurate, because deduced from the short period of 150 years, and from the observations of Timochares, in which he had no great confidence.

This motion of the starry heavens was long a matter of discussion, as a thing for which no physical reason could be assigned. But the establishment of the Copernican system reduced it to a very simple affair; the motion which was thought to affect all the heavenly bodies, is now acknowledged to be a deception, or a false judgment from the appearances. The earth turns round its own axis while it revolves round the sun, in the same manner as we may cause a child's top to spin on the brim of a mill-stone, while the stone is turning slowly round its axis. If the top spin steadily, without any wavering, its axis will always point to the zenith of the heavens; but we frequently see, that while it spins briskly round its axis, the axis itself has a slow conical motion round the vertical line, so that, if produced, it would slowly describe a circle in the heavens round the zenith point. The flat surface of the top may represent the terrestrial equator, gradually turning itself round on all sides. If this top were formed like a ball, with an equatorial circle on it, it would represent the whole motion very prettily, the only difference being, that the spinning motion and this wavering motion are in the same direction; whereas the diurnal rotation and the motion of the equinoctial points are in contrary directions. Even this dissimilarity may be removed, by making the top turn on a cap, like the card of a mariner's compass.

It is now a matter fully established, that while the earth revolves round the sun from west to east, in the plane of the ecliptic, in the course of a year it turns round its own axis from west to east in $23^h 56' 4''$, which axis is inclined to this plane in an angle of nearly $23^\circ 28'$: and that this axis turns round a line perpendicular to the ecliptic in 25,745 years from east to west, keeping nearly the same inclination to the ecliptic.—By this means, its pole in the sphere of the starry heavens describes a circle round the pole of the ecliptic at the distance of $23^\circ 28'$ nearly. The consequence of this must be, that the terrestrial equator, when produced to the sphere of the starry heavens, will cut the ecliptic in two opposite points, through which the sun must pass when he makes the day and night equal; and that these points must shift to the westward, at the rate of $50\frac{1}{2}$ seconds annually, which is the precession of the equinoxes. Accordingly this has been the received doctrine among astronomers for nearly three centuries, and it was thought perfectly conformable to appearances.

But Dr. Bradley, the most sagacious of modern astronomers, hoped to discover the parallax of the earth's orbit by observations of the actual position of the pole of the celestial revolution. Dr. Hooke had attempted this before, but with very imperfect instruments. The art of observing being now prodigiously improved, Dr. Bradley resumed this investigation. It will easily appear, that if the earth's axis keep parallel to itself, its extremity must describe in the sphere of the starry heavens a figure equal and parallel to its orbit round the sun; and if the stars be so near that this figure is a visible object, the pole of diurnal revolution will be in different distinguishable points of this figure. Consequently, if the axis describe the cone already mentioned, the pole will not describe a circle round the pole of the

ecliptic, but will have a looped motion along this circumference, similar to the absolute motion of one of Jupiter's satellites, describing an epicycle whose centre describes the circle round the pole of the ecliptic.

He accordingly observed such an epicyclical motion, and thought that he had now overcome the only difficulty in the Copernican system; but, on maturely considering his observations, he found this epicycle to be quite inconsistent with the consequences of the annual parallax, and it puzzled him exceedingly. One day, while taking the amusement of sailing about on the Thames, he observed that every time the boat tacked, the direction of the wind, estimated by the direction of the vane, seemed to change. This immediately suggested to him the cause of his observed epicycle, and he found it an optical illusion, occasioned by a combination of the motion of light with the motion of his telescope while observing the polar stars. Thus he unwittingly established an incontrovertible argument for the truth of the Copernican system, and immortalized his name by his discovery of the aberration of the stars.

He now engaged in a series of observations for ascertaining all the circumstances of this discovery. In the course of these, which were continued for 28 years, he discovered another epicyclical motion of the pole of the heavens, which was equally curious and unexpected. He found that the pole described an epicycle, whose diameter was about $18'$, having for its centre that point of the circle round the pole of the ecliptic in which the pole would have been found independent of this new motion. He also observed, that the period of this epicyclical motion was 18 years and seven months. It struck him, that this was precisely the period of the revolution of the nodes of the moon's orbit. He gave a brief account of these results to lord Macclesfield, then president of the Royal Society, in 1747. Mr. Machin, to whom he also communicated the observations, gave him in return a very neat mathematical hypothesis, by which the motion might be calculated.

Let E (pl. 142, fig. 1), be the pole of the ecliptic, and SPQ a circle distant from it $23^\circ 28'$, representing the circle described by the pole of the equator during one revolution of the equinoctial points. Let P be the place of this last mentioned pole at some given time, Round P describe a circle ABCD, whose diameter AC is $18'$. The real situation of the pole will be in the circumference of this circle; and its place, in this circumference, depends on the place of the moon's ascending node. Draw EPF and GPL perpendicular to it; let GL be the colure of the equinoxes, and EF the colure of the solstices. Dr. Bradley's observations showed that the pole was in A when the node was in L, the vernal equinox. If the node recede to H, the winter solstice, the pole is in B. When the node is in the autumnal equinox at G the pole is at C; and when the node is in F, the summer solstice, the pole is in D. In all intermediate situations of the moon's ascending node, the pole is in a point of the circumference ABCD, three signs or 90° more advanced.

Dr. Bradley, by comparing together a great number of observations, found that the mathematical theory, and the calculation depending on it, would correspond much better with the observations, if an eclipse were substituted for the circle ABCD, making the longer axis AC $18'$, and the shorter, BD, $16'$. Mr. D'Alembert determined,

PRECESSION.

by the physical theory of gravitation, the axis to be $18''$ and $13''.4$.

These observations, and this mathematical theory must be considered as so many facts in astronomy, and we must deduce from them the methods of computing the places of all celestial phenomena, agreeable to the universal practice of determining every point of the heavens by its longitude, latitude, right ascension, and declination.

It is evident, in the first place, that this equation of the pole's motion makes a change in the obliquity of the ecliptic. The inclination of the equator to the ecliptic is measured by the arch of a great circle intercepted between their poles. Now, if the pole be in O instead of P , it is plain that the obliquity is measured by EO instead of EP . If EP be considered as the mean obliquity of the ecliptic, it is augmented by $9''$ when the moon's ascending node is in the vernal equinox, and consequently the pole in A . It is, on the contrary, diminished $9''$ when the node is in the autumnal equinox, and the pole in C ; and it is equal to the mean when the node is in the colure of the solstices. This change of the inclination of the earth's axis to the plane of the ecliptic was called the nutation of the axis by sir Isaac Newton; who showed that a change of nearly a second must obtain in a year by the action of the sun on the prominent parts of the terrestrial spheroid. But he did not attend to the change which would be made in this motion by the variation which obtains in the disturbing force of the moon, in consequence of the different obliquity of her action on the equator, arising from the motion of her own oblique orbit. It is this change which now goes by the name nutation, and we owe its discovery entirely to Dr. Bradley. The general change of the position of the earth's axis has been termed deviation by modern astronomers.

The quantity of this change of obliquity is easily ascertained. It is evident from what has been already said, that when the pole is in O , the arch $ADCO$ is equal to the node's longitude from the vernal equinox, and that PM is its confine; and (on account of the smallness of AP in comparison of EP) PM may be taken for the change of the obliquity of the ecliptic. This is therefore $= 9'' + \cos. \text{long. node}$, and is additive to the mean obliquity, while O is in the semicircle BAD , that is, while the longitude of the node is from 9 signs to 3 signs; but subtractive while the longitude of the node changes from 3 to 9 signs.

But the nutation changes also the longitudes and right ascensions of the stars and planets, by changing the equinoctial points, and thus occasioning an equation in the precession of the equinoctial points. It was this circumstance which made it necessary for us to consider it in this place, while expressly treating of this precession. Let us attend to this derangement of the equinoctial points.

The great circle or meridian which passes through the poles of the ecliptic and equator is always the solstitial colure, and the equinoctial colure is at right angles to it: therefore when the pole is in P or in O , EP or EO is the solstitial colure. Let S be any fixed star or planet, and let SE be a meridian or circle of longitude; draw the circles of declination PS , OS , and the circles $M'EM'$, mEm' , perpendicular to PE , OE .

If the pole were in its mean place P , the equinoctial points would be in the ecliptic meridian $M'EM'$, or that meridian would pass through the intersections of the equator and ecliptic, and the

angle $M'ES$ would measure the longitude of the star S . But when the pole is in O , the ecliptic meridian mEm' will pass through the equinoctial points. The equinoctial points must therefore be to the westward of their mean place, and the equation of the precession must be additive to that precession: and the longitude of the star S will now be measured by the angle mES , which, in the case here represented, is greater than its mean longitude. The difference, or the equation of longitude arising from the nutation of the earth's

axis, is the angle OEP , or $\frac{OM}{OE}$. OM is the sine of

the angle CPO , which, by what has been already observed, is equal to the longitude of the node: Therefore OM is equal to $9'' + \text{long. node}$, and $\frac{OM}{OE}$ is equal to $\frac{9'' + \text{long. node}}{\sin. \text{obl. eclip.}}$. This

equation is additive to the mean longitude of the star when O is in the semicircle CBA , or while the ascending node is passing backwards from the vernal to the autumnal equinox; but it is subtractive from it while O is in the semicircle ADC , or while the node is passing backwards from the autumnal to the vernal equinox; or, to express it more briefly, the equation is subtractive, from the mean longitude of the star, while the ascending node is in the first six signs, and additive to it while the node is in the last six signs.

This equation of longitude is the same for all the stars, for their longitude is reckoned on the ecliptic (which is here supposed invariable); and therefore is affected only by the variation of the point from which the longitude is computed.

The right ascension, being computed on the equator, suffers a double change. It is computed from, or begins at, a different point of the equator, and it terminates at a different point; because the equator having changed its position, the circles of declination also change theirs. When the pole is at P , the right ascension of S from the solstitial colure is measured by the angle SPE , contained between that colure and the star's circle of declination. But when the pole is at O , the right ascension is measured by the angle SOE , and the difference of SPE and SOE is the equation of right ascension. The angle SOE consists of two parts, GOE and GOS ; GOE remains the same wherever the star S is placed, but GOS varies with the place of the star.—We must first find the variation by which GPE becomes GOE , which variation is common to all the stars. The triangles GPE , GOE have a constant side GE , and a constant angle G ; the variation PO of the side GP is extremely small, and therefore the variation of the angles may be computed by Mr. Cotes's Fluxionary Theorems. See Simpson's Fluxions, § 253, &c. As the tangent of the side EP opposite to the constant angle G , is to the sine of the angle EPG , opposite to the constant side EG , so is PO the variation of the side GP adjacent to the constant angle, to the variation x of the angle GPO , opposite to the constant side EG . This gives $x = \frac{9'' \times \sin. \text{long. node}}{\text{tang. obl. eclip.}}$.

This is subtractive from the mean right ascension for the first six signs of the node's longitude, and additive for the last six signs. This equation is common to all the stars.

The variation or the other part SOG of the angle, which depends on the different position of the hour circles PS and OS , which causes them to cut the equation in different points, where the arches of right ascension terminate may be discovered as

PRECESSION.

follows. The triangles SPG, SOG, have a constant side SG, and a constant angle G. Therefore, by the same Cotesian theorem, $\tan. SP: \sin. SPG = FO: y$, and y , or the second part of the nutation in right ascension, =

$$9^\circ \times \sin. \text{diff. R. A. of star and node.} \\ \cotan. \text{declin. star.}$$

The nutation also effects the declination of the stars. For SP, the mean codeclination, is changed into SO.—Suppose a circle described round S with the distance SO cutting SP in f ; then it is evident that the equation of declin. is $Pf = PO \times \cosine OPf = 9^\circ \times \sin. r. \text{ ascen. of star—long. of node.}$

Such are the calculations in constant use in our astronomical researches, founded on Machin's Theory. When still greater accuracy is required, the elliptical theory must be substituted, by taking (as is expressed by the dotted lines) O in that point of the ellipse described on the transverse axis AC, where it is cut by OM, drawn according to Machin's theory. All the change made here is the diminution of OM in the ratio of 18 to 13.4, and a corresponding diminution of the angle CPO. The detail of it may be seen in De la Lande's Astronomy, art. 2874; but is rather foreign to our present purpose of explaining the precession of the equinoxes. The calculations being in every case tedious, and liable to mistakes, on account of the changes of the signs of the different equations, the zealous promoters of astronomy have calculated and published tables of all these equations, both on the circular and elliptical hypothesis. And still more to abridge calculations, which occur in reducing every astronomical observation, when the place of a phenomenon is reduced from a comparison with known fixed stars, there have been published tables of nutation and precession, for some hundreds of the principal stars, for every position of the moon's node and of the sun.

It now remains to consider the precession of the equinoctial points, with its equations, arising from the nutation of the earth's axis as a physical phenomenon, and to endeavour to account for it upon those mechanical principles, which have so happily explained all the other phenomena of the celestial motions.

: This did not escape the penetrating eye of sir Isaac Newton; and he quickly found it to be a consequence, and the most beautiful proof, of the universal gravitation of all matter to all matter; and there is no part of his immortal work where his sagacity and fertility of resource shine more conspicuously than in this investigation. It must be acknowledged, however, that Newton's investigation is only a shrewd guess founded on assumptions of which it would be extremely difficult to demonstrate either the truth or falsity, and which required the genius of a Newton to pick out in such a complication of abstruse circumstances. The subject has occupied the attention of the first mathematicians of Europe since his time; and is still considered as the most curious and difficult of all mechanical problems. The most elaborate and accurate dissertations on the precession of the equinoxes are those of Sylvestra and Walmesley, in the Philosophical Transactions, published about the year 1754; that of Thomas Simpson, published in his Miscellaneous Tracts; that of Father Frisius, in the Memoirs of the Berlin Academy, and afterwards, with great improvements in his Cosmographia; that of Euler in the Memoirs of Berlin; that of D'Alembert in a separate disser-

tation; and that of De la Grange on the Libration of the Moon, which obtained the prize in the Academy of Paris, in 1769. We think the dissertation of Father Frisius the most perspicuous of them all, being conducted in the method of geometrical analysis; whereas most of the others proceed in the fluxionary and symbolic method, which is frequently deficient in distinct notions of the quantities under consideration, and therefore does not give us the same perspicuous conviction of the truth of the results. In a work like ours, it is impossible to do justice to the problem, without entering into a detail which would be thought extremely disproportioned to the subject by the generality of our readers. Yet those who have the necessary preparation of mathematical knowledge, and wish to understand the subject fully, will find enough here to give them a very distinct notion of it; and in the article ROTATION they will find the fundamental theorems, which will enable them to carry on the investigation. We shall first give a short sketch of Newton's investigation, which is of the most palpable and popular kind, and is highly valuable, not only for its ingenuity, but also because it will give our unlearned readers distinct and satisfactory conceptions of the chief circumstances of the whole phenomena.

Let S (fig. 2.) be the sun, E the earth, and M the moon, moving in the orbit NMCDn, which cuts the plane of the ecliptic in the line of the nodes Nn, and has one half raised above it, as represented in the figure, the other half being hid below the ecliptic. Suppose this orbit folded down; it will coincide with the ecliptic in the circle N m c d n. Let EX represent the axis of this orbit perpendicular to its plane, and therefore inclined to the ecliptic. Since the moon gravitates to the sun in the direction MS, which is all above the ecliptic, it is plain that this gravitation has a tendency to draw the moon towards the ecliptic. Suppose this force to be such that it would draw the moon down from M to i in the time that she would have moved from M to t , in the tangent to her orbit. By the combination of these motions, the moon will desert her orbit, and describe the line Mr, which makes the diagonal of the parallelogram; and if no further action of the sun be supposed, she will describe another orbit Mm', lying between the orbit MCDn and the ecliptic, and she will come to the ecliptic, and pass through it in a point n' , nearer to M than n is, which was the former place of her descending node. By this change of orbit, the line EX will no longer be perpendicular to it; but there will be another line Ex, which will now be perpendicular to the new orbit. Also the moon, moving from M to r , does not move as if she had come from the ascending node N, but from a point N' lying beyond it; and the line of the nodes of the orbit in this new position is N' n'. Also the angle MN'm is less than the angle MNm.

Thus the nodes shift their places in a direction opposite to that of her motion, or move to the westward; the axis of the orbit changes its position, and the orbit itself changes its inclination to the ecliptic. These momentary changes are different in different parts of the orbit, according to the position of the line of the nodes. Sometimes the inclination of the orbit is increased, and sometimes the nodes move to the eastward. But, in general, the inclination increases from the time that the nodes are in the line of syzygee, till they get into quadrature, after which it diminishes till the nodes

PRECESSION.

are again in syzygie. The nodes advance only while they are in the octants after the quadratures, and while the moon passes from quadrature to the node, and they recede in all other situations. Therefore the recess exceeds the advance in every revolution of the moon round the earth, and, on the whole, they recede.

What has been said of one moon would be true of each of a continued ring of moons surrounding the earth, and they would thus compose a flexible ring, which would never be flat, but waved according to the difference (both in kind and degree) of the disturbing forces acting on its different parts. But suppose these moons to cohere, and to form a rigid and flat ring, nothing would remain in this ring but the excess of the contrary tendencies of its different parts. Its axis would be perpendicular to its plane, and its position in any moment will be the mean position of all the axis of the orbits of each part of the flexible ring; therefore the nodes of this rigid ring will continually recede, except when the plane of the ring passes through the sun, that is, when the nodes are in syzygie; and (says Newton) the motion of these nodes will be the same with the mean motion of the nodes of the orbit of one moon. The inclination of this ring to the ecliptic will be equal to the mean inclination of the moon's orbit during any one revolution which has the same situation of the nodes. It will therefore be least of all when the nodes are in quadrature, and will increase till they are in syzygie, and then diminish till they are again in quadrature.

Suppose this ring to contract in dimensions, the disturbing forces will diminish in the same proportion, and in this proportion will all their effects diminish. Suppose its motion of revolution to accelerate, or the time of a revolution to diminish; the linear effects of the disturbing forces being as the squares of the times of their action, and their angular effects as the times, those errors must diminish also on this account; and we can compute what those errors will be for any diameter of the ring, and for any period of its revolution. We can tell, therefore, what would be the motion of the nodes, the change of inclination, and deviation of the axis, of a ring which would touch the surface of the earth, and revolve in 24 hours; nay, we can tell what these motions would be, should this ring adhere to the earth. They must be much less than if the ring were detached; for the disturbing forces of the ring must drag along with it the whole globe of the earth. The quantity of motion which the disturbing forces would have produced in the ring alone will now (says Newton) be produced in the whole mass; and therefore the velocity must be as much less as the quantity of matter is greater: But still all this can be computed.

Now there is such a ring on the earth: for the earth is not a sphere, but an elliptical spheroid. Sir Isaac Newton therefore engaged in a computation of the effects of the disturbing force, and has exhibited a most beautiful example of mathematical investigation. He first asserts, that the earth must be an elliptical spheroid, whose polar axis is to its equatorial diameter, as 229 to 230. Then he demonstrates, that if the sine of the inclination of the equator be called π , and if t be the number of days (sidereal) in a year, the annual motion of

then shows that the effect of the disturbing force on this ring is to its effect on the matter of the same ring, distributed in the form of an elliptical stratum (but still detached) as 5 to 2; therefore,

the motion of the nodes will be $360^\circ \times \frac{3\sqrt{1-\pi^2}}{10t}$

or $16' 16'' 24'''$ annually. He then proceeds to show, that the quantity of motion in the sphere is to that in an equatorial ring revolving in the same time, as the matter in the sphere to the matter in the ring, and as three times the square of a quadrantal arch to two squares of a diameter, jointly: Then he shows, that the quantity of matter in the terrestrial sphere is to that in the protuberant matter of the spheroid, as 52900 to 461 (supposing all homogeneous). From these premises it follows, that the motion of $16' 16'' 24'''$, must be diminished in the ratio of 10717 to 100, which reduces it to $9' 07'''$ annually. And this (he says) is the precession of the equinoxes, occasioned by the action of the sun; and the rest of the $50\frac{3}{4}''$, which is the observed precession, is owing to the action of the moon, nearly five times greater than that of the sun. This appeared a great difficulty: for the phenomena of the tides show that it cannot much exceed twice the sun's force.

Nothing can exceed the ingenuity of this process. Justly does his celebrated and candid commentator, Daniel Bernoulli, say (in his Dissertation on the Tides, which shared the prize of the French Academy with M'Laurin and Euler), that Newton saw through a veil what others could hardly discover with a microscope in the light of the meridian sun. His termination of the form and dimensions of the earth, which is the foundation of the whole process, is not offered as any thing better than a probable guess, in *re difficilima*; and it has been since demonstrated with geometrical rigour by M'Laurin.

His next principle, that the motion of the nodes of the rigid ring is equal to the mean motion of the nodes of the moon, has been most critically discussed by the first mathematicians, as a thing which could neither be proved nor refuted. Frisius has at least shown it to be a mistake, and that the motion of the nodes of the ring is double the mean motion of the nodes of a single moon; and that Newton's own principles should have produced a precession of $18\frac{1}{2}$ seconds annually, which removes the difficulty formerly mentioned.

His third assumption, that the quantity of motion of the ring must be shared with the included sphere, was acquiesced in by all his commentators, till D'Alembert and Euler, in 1749, shewed that it was not the quantity of motion round an axis of rotation which remained the same, but the quantity of momentum or rotatory effort. The quantity of motion is the product of every particle, by its velocity; that is, by its distance from the axis; while its momentum, or power of producing rotation, is as the square of that distance, and is to be had by taking the sum of each particle multiplied by the square of its distance from the axis. Since the earth differs so little from a perfect sphere, this makes no sensible difference in the result. It will increase Newton's precession about three fourths of a second.

The real source of Newton's mistake in the solution of this intricate and interesting problem was first detected by Mr. Landen, in the first volume of his Memoirs. That excellent mathematician discovered that when a rigid annulus revolves

a detached ring will be $360^\circ \times \frac{3\sqrt{1-\pi^2}}{4t}$. He

with two motions, one in its own plane, and the other round one of its diameters, half the motive force acting upon the ring is counteracted by the centrifugal force arising from the compound motion, and half only is efficacious or accelerating the plane of the annulus round its diameter. Mr. Landen did not expressly demonstrate this; but it has been done very elegantly by Dr. Brinkley, in the 7th volume of the Memoirs of the Irish Academy.

We cannot enter further upon this subject here; but beg to refer the mathematical reader to Dr. Milner's paper in the Philosophical Transactions, to Dr. Abram Robertson's paper in the Philosophical Transactions for 1807, to the Dissertation of Frisius already specified, and to the popular view of this problem by M. Laplace in his Exposition, book iv. ch. 13.

To find the precession in right ascension and declination.

Put d = the declination of a star,
and a = its right ascension;
then their annual variations of precessions will be nearly as follow:

viz. $20'' \cdot 084 \times \cos. a$ = the annual precession in declinat.

and $46'' \cdot 0619 + 20'' \cdot 084 \times \sin. a \times \text{tang. } d$
= that of right ascension. See the Connoissance des Temps for 1792, pa. 206, &c.

PRECIE. In botany. Early ripe. The name of an early sort of grape in Virgil. The fifty-first order in Linneus's Fragments; and the twenty-first in his Natural Orders: comprehending such plants as flower early in the spring.

PRECINCT. *s.* (*precinctus*, Latin.) Outward limit; boundary (*Hooker*).

PRECIOUSITY. *s.* (from *pretiosus*, Latin.) 1. Value; preciousness: not used. 2. Any thing of high price: not used (*More*).

PRECIOUS. *a.* (*precieux*, Fr. *pretiosus*, Lat.) 1. Valuable; being of great worth (*Ad-dison*). 2. Costly; of great price (*Milton*).

PRECIOUSLY. *ad.* (from *precious*.) Valuably; to a great price.

PRECIOUSNESS. *s.* (from *precious*.) Valuableness; worth; price (*Wilkins*).

PRECIPICE. *s.* (*præcipitium*, Latin.) A headlong steep; a fall perpendicular (*Sandys*).

PRECIPITANCE. PRECIPITANCY. *s.* (from *precipitant*.) Rash haste; headlong hurry (*Milton*).

PRECIPITANT. *a.* (*precipitans*, Latin.) 1. Falling or rushing headlong (*Phillips*). 2. Hasty; urged with violent haste (*Pope*). 3. Rashly hurried (*King Charles*).

PRECIPITANTLY. *ad.* (from *precipitant*.) In headlong haste; in a tumultuous hurry.

To **PRECIPITATE.** *v. a.* (*præcipito*, Lat.) 1. To throw headlong (*Wilkins*). 2. To urge on violently (*Dryden*). 3. To hasten unexpectedly (*Harvey*). 4. To hurry blindly or rashly (*Bacon*). 5. To throw to the bottom. A term of chemistry opposed to *sublime* (*Grew*).

To **PRECIPITATE.** *v. n.* 1. To fall headlong (*Shakspeare*). 2. To fall to the bottom

as a sediment (*Bacon*). 3. To hasten without just preparation (*Bacon*).

PRECIPITATE. *a.* (from the verb.) 1. Steeply falling (*Raleigh*). 2. Headlong; hasty; rashly hasty (*Clarend.*). 3. Hasty; violent (*Arbuthnot*).

PRECIPITATE, in chemistry, (*heeder-schlag*, Germ.) In a more limited and appropriate sense a substance thrown down from its solution in a menstruum by the application of a third or additional material, which detaches it, either by a greater affinity to itself or to the menstruum with which it has thus far been combined. (See the article **PRECIPITATION**.) It is necessary, however, for the name of a precipitate in this restricted sense, that the substance thus subsiding should fall in a flocculent or pulverulent form, since if the different particles unite in an angular polyhedral figure it will be a crystallization.

The term, however, is often used in a more extended sense to impart any visible substance, simple or compound, separated from its menstruum whether it sink or swim, or whether it be a crystal or a powder; and in this view precipitation forms one of the great operations in chemistry, and instead of being opposed to the phenomenon of crystallization, is directly opposed to that of solution. It is chiefly from the process of precipitation, as Berthollet has shown in his valuable essays on chemical statics, that philosophers have been led to deduce the supposed order of affinities between different substances.

The precipitates of most importance to attend to are those which occur in the case of acids, alkalies, or earths, and those in the case of metals and metallic compounds. We shall subjoin from Berthollet a few observations upon both these, connected with remarks offered by the Messrs. Aikin.

Among the former there are two principal kinds of precipitates which have been distinguished in chemistry; one, where to a compound produced by an acid and a base, each highly soluble in water, another acid is added which has a great affinity with the base, and forms with it a compound less soluble than the first. In this case the precipitate (which is sometimes but not always crystallized) is composed of the acid last added, in proportions that do not essentially vary. As for example, when sulphuric acid is added to a saturated solution of nitrat of potash a crystallized precipitate of sulphat of potash is produced, the proportions of which scarcely vary in any circumstances, though the actual quantity of precipitate is determined by the quantity of water and of sulphuric acid present.

The second kind of precipitate is that which has been usually supposed to be simple, and which takes place when to a compound of an acid and a base, insoluble or nearly so in water, an alkali or soluble earth is added, which by elective affinity unites with the acid and displaces the former base: and this latter now supposed to be uncombined, and insoluble in the quantity of liquid present, falls to the bot-

P R E C I P I T A T E.

om. This kind of precipitation is constantly resorted to when we wish to obtain the simple earths, as in adding an alkali to a solution of alum in order to precipitate the alumine, to Epsom salts to precipitate magnesia, &c. But the precipitate in all such cases is not (as has been usually supposed) the simple earth, since it always retains after the first operation a small and variable portion of the acid with which it was before combined. Thus, if the alumine, however well edolcorated, be re-dissolved in muriatic acid, and a salt of barytes be added, there will be a sensible precipitate of sulphat of barytes. This retention of acid is variable, and may be reduced to an insensible quantity, if not absolutely taken away by subsequent digestion in very concentrated alkali. Such precipitations therefore are not effected merely by simple affinity, but by a division of the acid into two portions, one of which, and by much the largest, goes to the alkali, and the other remains with the earth, and accompanies it in its precipitation. Even when no precipitation occurs, the acid may be proved to distribute itself in this manner; for as Bergman has remarked, if a calcareous salt be dissolved in fifty times its weight of water and an excess of potash or soda be added, no precipitation takes place, so that the acid continues in part to act upon the lime, and renders it soluble in a much less quantity of water than the lime alone would require for solution.

It may be assumed, therefore, as a general principle, and one that is of great importance in the explanation of chemical decomposition, that when a salt is composed of an acid and a base, insoluble, or little soluble by itself, the decomposition effected by any soluble base is the result not of a simple but a compound action, in which, on the one hand, the decomposing base unites with more or less of the acid and remains in solution, while the other base resumes its insolubility by the separation of part of its acid, and forms a precipitate with the remainder.

This observation will be found to apply still more strikingly in the formation of metallic precipitates, and of those salts which (like the subsulphat of mercury or turbith) were formerly taken for simple oxyds, but are now found to be salts with excess of oxyd.

The metal of any metallic solution in any acid is always in the state of an oxyd, so that the solution must contain at least three substances, the acid, the metal, and oxygen united with the metal. But the proportion of the latter is subject to a great number of variations, and is different both with the several metals and with the same metal in different circumstances.

A metallic solution may be decomposed and its metallic part precipitated either in the reguline state or as an oxyd; and these two methods which have been adopted in the analysis of metallic bodies require to be considered separately.

When a carbonated alkali is added to a metallic solution the precipitate is a carbonated

oxyd of the metal, and like the other carbonats, effervesces on the addition of a stronger acid. But when a pure acid is added only to saturation the precipitate is in some instances nearly a pure oxyd, but in the greater number is an oxyd retaining a small proportion of the acid with which it was united. This acid, however, is not sufficient to render it soluble, and it may be generally entirely taken away by subsequent digestion in a concentrated fixed alkali, provided the oxyd is not soluble therein. Hence the first action of alkalies on most metallic solutions is to cause an unequal division of the acid, the greater part of which unites with the alkali, and the remainder falls down along with the oxyd now rendered insoluble. If ammonia be the alkali employed there is also in general a partition of the alkali, and the precipitate is a quadruple compound of the metal, the oxygen united with it, and a small portion of the acid, and of the ammonia; and the solution contains the greater part of the acid of the alkali, and often a small part of the metallic oxyd sufficient to be very sensible to the taste and to chemical tests. According to Proust, lime also, when used as a precipitant, enters in a small proportion into the precipitate.

Metallic solutions sometimes yield precipitates on the mere addition of water, by the simple distribution of the constituents into two portions, a soluble and an insoluble one, the former of which has an excess of acid, and the latter of oxyd. Thus when the clear nitrat of bismuth is diluted with water a white precipitate falls down, which is chiefly oxyd of bismuth, and the supernatant liquor contains an excess of acid and a small portion of metal, which may be separated by evaporation, or by an alkali. In like manner, if sulphuric acid and mercury be treated together, sulphureous acid is given out, and the white mass that remains is an uniform acid sulphat which deliquesces into a dense solution. But if hot water be added, the turbeth or yellow subsulphat of mercury is precipitated, and the solution contains an acid sulphat.

The second species of metallic precipitates are those in which the metal appears in its reguline form. This takes place when one metal is precipitated by another, as when a piece of iron is immersed in a solution of copper, and also when phosphorus is kept for some time in certain metallic solutions.

Before the discovery of oxygen, and of the oxydation of metals being necessary to their solution in acids, the precipitation of one metal by another was supposed to be produced by simple elective attraction; and the respective affinities of the metals for the acids was put down in the order of the precipitations which they produced. But this explanation, though true in general, does not explain a number of apparent anomalies in metallic precipitation, so that we must take into consideration the force of other agents and other affinities.

The order of the precipitation of one metal by another is the following among those that have been most accurately examined,—zinc, iron,

lead, tin, copper, silver, mercury, gold: that is to say, zinc precipitates all the other metals; iron precipitates all but zinc; lead all but zinc and iron, &c.

But sometimes the precipitation fails with solutions in one acid though it succeeds in others: thus zinc separates iron in the metallic state from muriatic acid, but only as an oxyd from the nitric. A small excess of acid is necessary to begin the process in all cases.

During this operation the following affinities must act, namely, that of the precipitant (or metal by which the separation is effected) for the oxygen of the metal already dissolved; that of the oxyd thus produced for the acid of the solution; and to this Berthollet adds, that of the two metals for each other when in the reguline state. The sum of these affinities must overcome that which exists between the constituent parts of the metallic salt intended to be decomposed.

The metals which phosphorus separates from their solutions in the reguline state are principally gold, silver, mercury, and copper. Thus if a stick of clean newly-melted phosphorus be immersed in an acidulated solution of sulphat of copper, in a day or two it becomes beautifully spangled with little knobs of bright metallic copper which gradually increase to a thick crust, after which if the stick be put into boiling water the phosphorus will melt out and leave a delicate hollow cylinder of copper.

PRECIPITATELY. *ad.* (from *precipitate*.) 1. Headlong; steeply down. 2. Hastily; in blind hurry (*Pope*).

PRECIPITATION. *s.* (from *precipitate*.) 1. The act of throwing headlong (*Shakspeare*). 2. Violent motion downward (*Woodward*). 3. Tumultuous hurry; blind haste (*Woodward*).

PRECIPITATION. (from *præcipito*, to cast down.) In chemistry. When two bodies are united, for instance, an acid and an oxyd, or metallic calx, and a third body is added, such as an alkali, which has a greater affinity with the acid than the metallic oxyd, the consequence is, that the alkali combines with the acid, and the oxyd, thus deserted, appears in a separate state at the bottom of the vessel in which the operation was performed. This decomposition is commonly known by the name of precipitation, and the substance that sinks is named a precipitate. The substance, by the addition of which the phenomenon is produced, is denominated the precipitant.

By this operation, bodies are recovered from their solution, by means of the addition of some other substance, with which either the menstruum or the body dissolved have a greater affinity than they have with each other.

Precipitation, therefore, is of two kinds; one, where the substance superadded unites with the menstruum, and occasions that which was before dissolved to be thrown down; the other, in which it unites with the dissolved body, and falls with it to the bottom. Of the first, we have an example in the precipitation of sulphur from alkaline lixivium, by the means

of acids; of the second, in the precipitation of mercury from aquafortis by the muriatic acid.

The subjects of this operation, as well those which are capable of being precipitated, as those which precipitate, will readily appear by the Table of Attractions.

The manner of performing it is so simple, as to need no particular directions. All that is required, is to add the precipitant by degrees, as long as it continues to occasion any precipitation. When the whole of the powder has fallen, it is to be well edulcorated, that is, washed in several fresh parcels of water, and afterwards dried for use.

When metals are employed as precipitants, as in the purification of martial vitriol from copper by the addition of fresh iron, they ought to be perfectly clean, and free from any rusty or greasy matter, otherwise they will not readily, if at all, dissolve, and consequently the precipitation will not succeed; for the substance to be precipitated separates only by the additional one dissolving and taking its place. The separated powder, often, instead of falling to the bottom, lodges upon the precipitant, from which it must be occasionally shaken off, for reasons sufficiently obvious.

Though, in this operation, the precipitated powder is generally the part required for use, yet some advantage may be frequently made of the liquor remaining after the precipitation. Thus, when fixed alkaline salt is dissolved in water and sulphur dissolved in this lixivium, the addition of acids separates and throws down the sulphur, only in virtue of the acid uniting with, and neutralizing the alkali by which the sulphur was held dissolved; consequently, if the precipitation be made with the vitriolic acid, and the acid gradually dropt in till the alkali be completely saturated, that is, as long as it continues to occasion any precipitation or turbidness, the liquor will yield, by proper evaporation and crystallization, a neutral salt, composed of the vitriolic acid and fixed alkali, that is, vitriolated tartar. In like manner, if the precipitation be made with the nitrous acid, a true nitre; if with the muriatic, the salt called cubic nitre; and if with the acid of vinegar, the kali acetatum.

PRECIPITOUS. *a.* (*præcipitis*, Latin.) 1. Headlong; steep (*King Charles*). 2. Hasty; sudden (*Evelyn*). 3. Rash; Heady (*Dryden*).

PRECISE. *a.* (*præcisus*, Latin.) 1. Exact; strict; nice; having strict and determinate limitations (*Hooker*). 2. Formal; finical (*Addison*).

PRECISELY. *ad.* (from *precise*.) 1. Exactly; nicely; accurately (*Newton*). 2. With superstitious formality; with too much scrupulosity.

PRECISENESS. *s.* (from *precise*.) Exactness; rigid nicety (*Watts*).

PRECISION. *s.* (from *precise*.) 1. One who limits or restrains (*Shakspeare*). 2. One who is superstitiously rigorous (*Watts*).

PRECISION. *s.* (*precision*, French.) Exact limitation (*Pope*).

PRECISIVE. *a.* (from *precisus*, Latin.) Exactly limiting (*Watts*).

TO PRECLUDE. *v. n.* (*præcludo*, Latin.) To shut out or hinder by some anticipation (*Pope*).

PRECOCIOUS. *a.* (*præcociis*, Latin; *precoce*, French.) Ripe before the time (*Br.*).

PRECOCITY. *s.* (from *precocious*.) Ripeness before the time (*Howel*).

TO PRECOGITATE. *v. á.* (*præcogito*, Latin.) To consider or scheme beforehand.

PRECOGNITION. *s.* (*præ* and *cognitio*, Latin.) Previous knowledge; antecedent examination.

PRECONCEIT. *s.* (*pre* and *conceit*.) An opinion previously formed (*Hooker*).

TO PRECONCEIVE. *v. a.* (*pre* and *conceive*.) To form an opinion beforehand; to imagine beforehand (*South*).

PRECONCEPTION. *s.* (*pre* and *conception*.) Opinion previously formed (*Hakewill*).

PRECONTRACT. *s.* (*pre* and *contract*.) A contract previous to another (*Shakspeare*).

TO PRECONTRACT. *v. a.* To contract or bargain beforehand (*Ayliffe*).

PRECOP, or **PEREKOP**, a town and fortress of Russia, in the government of Catharienslaf, and province of Taurida, seated on the isthmus that joins the Crimea to the continent. A deep trench, four miles in length, is cut across the isthmus, over which is a bridge, and upon that a vaulted gate, called the Golden Gate of the Tartars. The town is now reduced to about 60 wooden houses; and its only riches consist of the salt works in its vicinity. It is 65 miles S.E. of Cherson. Lon. 35. 34 E. Lat. 46. 8 N.

PRECORDIA, in anatomy, a general name for the parts situated about the heart, in the forepart of the thorax; as the diaphragm, pericardium, and even the heart itself, with the spleen, lungs, &c.

PRECURSE. *s.* (from *præcurro*, Latin.) Forerunning (*Shakspeare*).

PRECURSOR. *s.* (*præcursor*, Latin.) Forerunner; harbinger (*Pope*).

PREDACEOUS. *a.* (from *præda*, Latin.) Living by prey (*Derham*).

PREDAL. *a.* (from *præda*, Latin.) Robbing; practising plunder (*Sa. Boyse*).

PREDATORY. *a.* (*predatorius*, Latin.)

1. Plundering; practising rapine (*Bacon*).

2. Hungry; preying; rapacious; ravenous (*Bacon*).

PREDECEASED. *a.* (*pre* and *deceased*.) Dead before (*Shakspeare*).

PREDECESSOR. *s.* (*predecessor*, Fr.)

1. One that was in any state or place before another (*Prior*). 2. Ancestor.

PREDESTINARIAN. *s.* (from *predestinate*.) One that holds the doctrine of predestination (*Decay of Piety*).

TO PREDESTINATE. *v. a.* (*predestiner*, French.) To appoint beforehand by irreversible decree (*Shakspeare*).

TO PREDESTINATE. *v. n.* To hold predestination. In ludicrous language (*Dryden*).

PREDESTINATION, the decree of God, whereby he is supposed to have, from all eternity, unchangably appointed whatsoever comes to pass; and hath more especially fore-ordained certain individuals of the human race to everlasting happiness, and hath passed by the rest, and fore-ordained them to everlasting misery. The former of these are called the elect, and the latter are called the reprobate.

This doctrine is the subject of one of the most perplexing controversies that has occurred among mankind. But it is not altogether peculiar to the Christian faith. The opinion, that whatever occurs in the world at large, or in the lot of private individuals, is the result of a previous and unalterable arrangement by that Supreme Power which presides over nature, has always been a favourite opinion among the vulgar, and has been believed by many speculative men.

The ancient Stoics, Zeno and Chrysippus, whom the Jewish Essenes seem to have followed, asserted the existence of a Deity that, acting wisely, but necessarily, contrived the general system of the world; from which, by a series of causes, whatever is now done in it unavoidably results. This series or concatenation of causes, they held to be necessary in every part; and that God himself is so much the servant of necessity and of his own decrees, that he could not have made the smallest object in the world otherwise than it now is, much less is he able to alter any thing.

According to the words of Seneca, “Eadem necessitas et Deos alligat. Irrevocabilis divina pariter atque humana cursus vehit. Ille ipse omnium condito ac rector scripsit quidem fata sed sequitur. Semper parat, semel jussit.”

“The same chain of necessity constrains both gods and men. Its unalterable course regulates divine as well as human things. Even he who wrote the Fates, the Maker and Governor of all things, submits to them. He did but once command, but he always obeys.” The stoical fate differs, however, from the Christian predestination in several points. They regard the divine nature and will as a necessary part of a necessary chain of causes; whereas the Christians consider the Deity as the Lord and Ruler of the Universe, omnipotent and free, appointing all things according to his pleasure. Being doubtful of the immortality of the soul, the Stoics could have no idea of the doctrine of election and reprobation; nor did they ever doubt their own freedom of will, or power of doing good as well as evil, as we shall presently see the Christian predestinarians have done.

Mahomet introduced into his Koran the doctrine of an absolute predestination of the course of human affairs. He represented life and death, prosperity and adversity, and every event that befalls a man in this world, as the result of a previous determination of the one God who rules over all; and he found this opinion the best engine for inspiring his followers with

P R E D E S T I N A T I O N .

that contempt of danger which, united to their zeal, has extended the empire of their faith over the fairest portion of the habitable globe.

The controversy concerning predestination first made its appearance in the Christian church about the beginning of the fifth century. See Mosheim's Instit. Hist. Eccl. Pelagius a British, and Celestius an Irish monk, who both lived at Rome during that period, and were with justice celebrated for their exemplary piety, and integrity, and great learning, contended that the doctrines of predestination and original sin were false. On the contrary, the famous Augustine, bishop of Hippo, strenuously asserted the depravity of human nature since the fall of the first man, the necessity of a special interposition of divine grace to enable us to do any one good action; and, consequently, that none could obtain salvation excepting those whom God has thought fit to elect, and upon whom he bestows this grace. In the course of the same century these opinions assumed a variety of forms and modifications. One party, called Predestinarians, carried Augustine's doctrine fully further than he himself had ventured to do in express words; and asserted, that God had not only predestinated the wicked to punishment, but also that he had decreed that they should commit those very sins on account of which they are hereafter to be punished. Another party moderated the doctrine of Pelagius, and were called Semipelagians. Their peculiar opinion is expressed in a different manner by different writers; but all the accounts sufficiently agree. Thus, some represent them as maintaining that inward grace is not necessary to the first beginning of repentance, but only to our progress in virtue. Others said that they acknowledge the power of grace, but held that faith depends upon ourselves, and good works upon God; and it is agreed upon all hands, that these Semipelagians held that predestination is made upon the foresight of good works. The assistance of Augustine, though then far advanced in life, was called in to combat these tenets, and he wrote several treatises upon the subject. In all these he strenuously maintained, that the predestination of the elect was independent of any foresight of their good works, but was according to the good pleasure of God only; and that perseverance comes from God, and not from man. Thereafter the doctrine of Augustine, or St. Austin as he is often called, became general. He was the oracle of schoolmen. They never ventured to differ from him in sentiment: they only pretended to dispute about the true sense of his writings.

The whole of the earliest reformers maintained these opinions of Augustine. They assumed under Luther a more regular and systematic form than they had ever formerly exhibited. But as the Lutherans afterwards abandoned them, they are now known by the name of Calvinistic Doctrines, from John Calvin, of Geneva. He asserted, that the everlasting condition of mankind in a future world was

determined from all eternity by the unchangeable decree of the Deity, arising from his sole good pleasure or free will.

There are two kinds of Calvinists or Predestinarians, viz. the Supralapsarians, who maintain that God did originally and expressly decree the fall of Adam, as a foundation for the display of his justice and mercy; while those who maintain that God only permitted the fall of Adam are called Sublapsarians, their system of decrees concerning election and reprobation being, as it were, subsequent to that event. But, as Dr. Priestley justly remarks, if we admit the divine prescience, there is not, in fact, any difference between the two schemes; and accordingly that distinction is now seldom mentioned.

The points chiefly at issue between the Calvinists and Arminians are the following.—First, with what views and purposes did God create the world and frame his decrees concerning mankind? Did he contrive a great unalterable scheme of creation and providence only for the sake of manifesting his own glory and perfections? Or did he first consider the free motions of those rational agents whom he intended to create, and frame his decrees upon the consideration of what they might choose or do in all the various circumstances in which he intended to place them? The second and following questions are branches of this leading one.—Did Christ die for a particular portion of the human race, who shall therefore certainly be saved? or was his death intended as a benefit to all, from which none are excluded excepting those who willingly reject it? Is the divine grace certainly and irresistibly efficacious in all those minds to which it is given? or does its effect depend upon the good use which men may or may not make of it? Can any good action be done without it? Do those who have once received it certainly persevere and obtain salvation? or is it possible for any of them to fall away and perish finally? These are questions the discussion of which would lead us far beyond our usual limits, and the tediousness of it would hardly be compensated by any prospect of utility.

The weak side of the Calvinistic doctrine consists in the impossibility of reconciling the absolute and unconditional decree of reprobation with our ideas of the justice and goodness of God. The weak side of the Arminian scheme consists in the difficulty of accounting for the certainty of the divine foreknowledge, upon the supposition of a contingency of events, or an absolute freedom of will in man.

To elude the former of these difficulties, some of the late writers upon philosophical necessity, and Dr. Priestley is among the number, have given up the doctrine of reprobation, and asserted that this world is only a state of preparation for another, in which all men of every description and character shall attain to final and everlasting happiness, when God shall be all, and in all. On the other side, some of the supporters of free agency, and

Montesquieu is among the number, have been disposed to deny the divine attribute of prescience.

Whatever may be thought of the practical tendency of the two most prevailing opinions, there is one remark which we think ourselves bound in justice to make, although it appears to us to be somewhat singular. It is this, that from the earliest ages down to our own days, if we consider the character of the ancient Stoics, the Jewish Essenes, the modern Calvinists, and Jansenists, when compared with that of their antagonists the Epicureans, the Saducees, Arminians and the Jesuits, we shall find that they have excelled in no small degree in the practice of the most rigid and respectable virtues, and have been the highest honour of their own ages, and the best models for imitation to every age succeeding. At the same time, it must be confessed, that their virtues have often been rendered unamiable by a tinge of gloomy and severe austerity.

So far as the speculative foundation of their principles is considered, however, neither party seems liable to censure in a moral point of view. Each of them wishes to support, though in a different manner from the other, the honour of the divine character. The Calvinists begin their argument with the notion of infinite perfection, independency, and absolute sovereignty, and thence deduce their opinions; making every difficulty yield to these first and leading ideas. Their opponents are more jealous of the respect due to the divine attributes of justice, truth, holiness, and mercy, and deduce their sentiments from the idea which they have formed of these. Each party lays down general maxims that are admitted by the other, and both argue plausibly from their first principles. These are strong grounds for mutual charity and forbearance. For our own parts, we have long been of opinion that there is an intermediate point between these opposed systems, in which all that is good in both will be found to meet, and all that is objectionable excluded.

PREDESTINATOR. *s.* (from *predestinate*.) One that holds predestination or the prevalence of preestablished necessity (*Cowley*).

To PREDESTINE. *v. a.* (*pre* and *destine*.) To decree beforehand.

PREDETERMINATION. *s.* (*predetermination*, French.) Determination made beforehand (*Hammond*).

To PREDETERMINE. *v. a.* (*pre* and *determine*.) To doom or confine by previous decree; to judge or settle principles (*Hale*).

PRE'DIAL. *a.* (*prædium*, Latin.) Consisting of farms (*Ayliffe*).

PRE'DICABLE. *a.* (*predicable*, French; *predicabilis*, Latin.) Such as may be affirmed of something.

PRE'DICABLE. *s.* (*prædicabile*, Latin.) A logical term, denoting one of the five things which can be affirmed of any thing (*Watts*).

PREDICAMENT. *s.* (*predicament*, Fr. *prædicamentum*, Latin.) 1. A class or arrange-

ment of beings or substances ranked according to their natures: called also *catagorema* or *catagory* (*Harris*). 2. Class or kind described by any definite marks (*Shakspeare*).

PREDICAMENTAL. *a.* (from *predicament*.) Relating to predicaments.

PREDICANT. *s.* (*prædicans*, Latin.) One that affirms any thing.

To PRE'DICATE. *v. a.* (*prædico*, Latin.) To affirm any thing of another thing (*Locke*).

To PRE'DICATE. *v. n.* To affirm; to comprise an affirmation (*Hale*).

PREDICATE. *s.* (*prædicatum*, Latin.) That which is affirmed or denied of the subject: as, *man is rational*; *man is not immortal*.

PREDICA'TION. *s.* (*predicatio*, Latin.) Affirmation concerning any thing (*Locke*).

To PREDICT. *v. a.* (*prædictus*, Latin.) To foretell; to foreshow (*Gov. of the Tongue*).

PREDI'CTION. *s.* (*predictio*, Latin.) Prophecy; declaration of something future (*South*).

PREDI'CTOR. *s.* (from *predict*.) Foreteller.

PREDIGESTION. *s.* (*pre* and *digestion*.) Digestion too soon performed (*Bacon*).

To PREDISPOSE. *v. a.* (*pre* and *dispose*.) To adapt previously to any secret purpose (*South*).

PREDISPOSING CAUSE. (*causa prædugmena*.) In medicine. That which renders the body susceptible of disease. The most frequent predisposing causes of diseases are, the temperament and habit of the body, idiosyncrasy, age, sex, and structure of the part diseased.

PREDISPOSITION. (*prædispositio*.) In medicine. That constitution or state of the solids or fluids, or of both, which disposes the body to the action of disease.

PREDISPOSITION. *s.* (*pre* and *disposition*.) Previous adaptation to any certain purpose (*Wiseman*).

PREDOMINANCE. **PREDOMINANCY.** *s.* (*præ* and *dominor*, Latin.) Prevalence; superiority; ascendancy; superiour influence (*Shakspeare*, *Brown*).

PREDOMINANT. *a.* (*predominant*, Fr.) Prevalent; supreme in influence; ascendant (*Shakspeare*).

To PRE'DOMINATE. *v. n.* (*predominer*, French.) To prevail; to be ascendant; to be supreme in influence (*Newton*).

To PRE'ELECT. *v. a.* (*pre* and *elect*.) To choose by previous decision.

PREE'MINENCE. *s.* (*preeminence*, Fr.) 1. Superiority of excellence (*Addison*). 2. Precedence; priority of place (*Hooker*). 3. Superiority of power or influence (*Brown*).

PREE'MINENT. *a.* (*preeminent*, French.) Excellent above others (*Sprat*).

PREEMPTION. *s.* (*præemptio*, Latin.) The right of purchasing before another (*Carew*).

To PREEN. *v. a.* (*pruinen*, Dutch.) To trim the feathers of birds, to enable them to glide more easily through the air (*Bailey*).

To PREENGA'GE. *v. a.* (*pre* and *engage*.)

P R E

To engage by precedent ties or contracts (Rogers).

PREENGAGEMENT. *s.* (from *preengage*.) Precedent obligation (Boyle).

To PREESTABLISH. *v. a.* (*pre* and *establish*.) To settle beforehand.

PREESTABLISHMENT. *s.* (from *preestablish*.) Settlement beforehand.

To PREEXIST. *v. a.* (*præ* and *existo*, Latin.) To exist beforehand (Dryden).

PREEXISTENCE. *s.* (*preexistence*, Fr.) 1. Existence before (Burnet). 2. Existence of the soul before its union with the body (Addison).

PREEXISTENT. *a.* (*preexistent*, French.) Existing beforehand; preceding in existence (Pope).

PREFACE. *s.* (*preface*, French.) Something spoken introductory to the main design; introduction; something proemial (Peacham).

To PREFACE. *v. n.* (*præfari*, Lat.) To say something introductory (Spectator).

To PREFACE. *v. a.* 1. To introduce by something proemial (Southern). 2. To face; to cover (Cleaveland).

PREFACER. *s.* (from *preface*.) The writer of a preface (Dryden).

PREFATORY. *a.* (from *preface*.) Introductory (Dryden).

PREFECT, in ancient Rome, one of the chief magistrates who governed in the absence of the kings, consuls, and emperors. This power was greatest under the emperors. His chief care was the government of the city, taking cognizance of all crimes committed therein and within 100 miles.

PREFECTURE. *s.* (*prefecture*, French; *præfectura*, Latin.) Command; office of government.

To PREFER. *v. a.* (*preferer*, French. *præfero*, Latin.) 1. To regard more than another (Romans). 2. To advance; to exalt; to raise (Clarendon). 3. To present ceremoniously (Pope). 4. To offer solemnly; to propose publicly; to exhibit (Sandys).

PREFERABLE. *a.* (*preferable*, French; from *prefer*.) Eligible before something else (Locke).

PREFERABLENESS. *s.* (from *preferable*.) The state of being preferable.

PREFERABLY. *ad.* (from *preferable*.) In preference; in such a manner as to prefer one thing to another (Dennis).

PREFERENCE. *s.* (*preference*, Fr. from *prefer*.) The act of preferring; estimation of one thing above another; election of one rather than another (Sprat).

PREFERER. *s.* (from *prefer*.) One who prefers.

PREFERMENT. *s.* (from *prefer*.) 1. Advancement to a higher station (Shakspeare). 2. A place of honour or profit (L'Estrange). 3. Preference; not in use (Brown).

To PREFIGURATE. *v. a.* (*præ* and *figuro*, Latin.) To show by an antecedent representation.

PREFIGURATION. *s.* (from *prefigure*.) Antecedent representation (Norris).

P R E

To PREFIGURE. *v. a.* (*præ* and *figuro*, Latin.) To exhibit by antecedent representation (Hammond).

To PREFINE. *v. a.* (*præfino*, Latin.) To limit beforehand (Knolles).

To PREFIX. *v. a.* (*præfigo*, Latin.) 1. To appoint beforehand (Sandys). 2. To settle; to establish (Hale). 3. To put before another thing: as, he prefixed an advertisement to his book.

PREFIX. *s.* (*præfixum*, Latin.) Some particle put before a word, to vary its significance (Brown).

PREFIXION. *s.* (*prefixion*, Fr. from *prefix*.) The act of prefixing.

To PREFORM. *v. a.* (*pre* and *form*.) To form before hand; not in use (Shakspeare).

PREGNANCY. Utero gestation. The particular manner in which pregnancy takes place has hitherto remained involved in obscurity, notwithstanding the laborious investigation of the most eminent philosophers of all ages.

Although pregnancy is a state which (with a few exceptions) is natural to all women, it is in general the source of many disagreeable sensations, and often the cause of diseases, which might be attended with the worst of consequences if not properly treated.

It is now, however, universally acknowledged, that those women who bear children enjoy, usually, more certain health, and are much less liable to dangerous diseases, than those who are unmarried, or who prove barren. See MIDWIFERY.

PREGNANT. *a.* (*pregnans*, Latin.) 1. Teeming; breeding (Prior). 2. Fruitful; fertile; impregnating (Dryden). 3. Full of consequence (Woodward). 4. Evident; plain; clear; obsolete (Shak.). 5. Easy to produce any thing (Shak.). 6. Free; kind; obsolete (Shakspeare).

PREGNANTLY. *ad.* 1. Fruitfully. 2. Fully; plainly; clearly (Shakspeare).

PREGUSTATION. *s.* (*præ* and *gusto*, Latin.) The act of tasting before another.

PREHENSILE, or PRENSILE, in zoology, a term applied to the tails of animals when they have the power of coiling them round other substances and suspending their bodies by them.

To PREJUDGE. *v. a.* (*prejurer*, French.) To determine any question beforehand; generally to condemn beforehand (Swift).

To PREJUDICATE. *v. a.* (*præ* and *judico*, Latin.) To determine beforehand to disadvantage (Sandys).

PREJUDICATE. *a.* (from the verb.) 1. Formed by prejudice; formed before examination (Watts). 2. Prejudiced; prepossessed by opinions (Brown).

PREJUDICATION. *s.* (from *prejudicate*.) The act of judging without examination.

PREJUDICE. *s.* (*prejudice*, French; *prejudicium*, Latin.) 1. Prepossession; judgment formed beforehand without examination (Clarendon). 2. Mischief; detriment; hurt; injury (Bacon).

P R E J U D I C E.

PREJUDICE, or PREJUDGMENT, from *præ* and *judicium*, means a judgment formed beforehand, without examination; the preposition *præ* expressing an anticipation, not so much of time as of knowledge and due attention: hence the schoolmen have called it anticipation and a preconceived opinion.

Prejudice arises from the associating principle, and it is a weakness from which no human mind can be wholly free. Some are indeed much more than others under its influence; but there is no man who does not occasionally act upon principles, the propriety of which he never investigated; or who does not hold speculative opinions, into the truth of which he never seriously enquired. Our parents and tutors, yea our very nurses, determine a multitude of our sentiments: our friends, our neighbours, the custom of the country where we dwell, and the established opinions of mankind, form our belief; the great, the pious, the learned, and the ancient, the king, the priest, and the philosopher, are characters of mighty efficacy to persuade us to regulate our conduct by their practice, and to receive as truth whatever they may dictate.

The case cannot indeed be otherwise. The occasions of acting are so frequent, and the principles of action are so various, that were a man to investigate accurately the value of every single motive which presents itself to his mind, and to balance them fairly against each other, the time of acting would in most instances pass away long before he could determine what ought to be done; and life would be wasted in useless speculation. The great laws of religion and morality, which ought to be the general and leading principles of action, no man of science will take upon trust; but in the course of a busy life a thousand circumstances will occur in which we must act with such rapidity, that, after being satisfied of the lawfulness of what we are about to do, we must, for the prudence of it, confide entirely in the general customs of our country, or in the practice of other individuals placed in circumstances similar to ours. In all such cases, though we may act properly, we act from prejudice.

But the dominion of prejudice is not confined to the actions of the man of business: it extends over the speculations of the philosopher himself, one half of whose knowledge rests upon no other foundation. All human sciences are related to each other (see *PHILOSOPHY*), and there is hardly one of them in which a man can become eminent unless he has some general acquaintance with the whole circle; but no man could ever yet investigate for himself all those propositions which constitute the circle of the sciences, or even comprehend the evidence upon which they rest, though he admits them perhaps as truths incontrovertible. He must therefore receive many of them upon the authority of others, or, which is the same thing, admit them by prejudice.

To this reasoning it may be objected, that

when a man admits as true abstract propositions, which, though not self-evident, he cannot demonstrate, he admits them not by prejudice, but upon testimony, which has been elsewhere shown to be a sufficient foundation for human belief. The objection is plausible, but it is not solid; for testimony commands belief only concerning events, which, falling under the cognizance of the senses, preclude all possibility of mistake; whereas abstract propositions, not self evident, can be proved true only by a process of reasoning or by a series of experiments; and in conducting both these, the most vigorous mind is liable to mistake. When sir Isaac Newton told the world that it was the fall of an apple which first suggested to him the general law of gravitation, he bore testimony to a fact concerning which he could not be mistaken; and we receive his testimony for the reasons assigned in the article referred to. When he lays down the method of obtaining the fluxion or moment of the rectangle or product of two indeterminate quantities, which is the main point in his doctrine of fluxions, he labours to establish that method on the basis of demonstration; and whoever makes use of it in practice, without understanding that demonstration, receives the whole doctrine of the modern geometrical analysis, not as a matter of fact upon the credit of sir Isaac's testimony, but as a system of abstract truth on the credit of his understanding: in other words he is a fluxionist by prejudice.

In vain will it be said, that in mathematical demonstration there is no room for mistake; and that therefore the man who implicitly adopts the method of fluxions may be considered as relying upon the veracity of its author, who had no inducement to deceive him, and whose comprehension was confessedly greater than his. In fluxionary mathematics, which treat of matters of which it is extremely difficult, if not impossible, to have adequate and steady conceptions, the most comprehensive mind is liable to mistake; and it is well known that the celebrated bishop of Cloyne wrote his Analyst to prove that the incomparable author of the method of fluxions had committed two mistakes in his fundamental proposition, which balancing one another, produced a true conclusion by false reasoning. One or other of these great men, of whom the least was an eminent mathematician, must have been bewildered in his reasoning, and have fallen into error; and therefore whoever follows either of them implicitly without perceiving the error of the other, is unquestionably under the influence of prejudice. This was long the case with the writer of the present article. He perceived not the error of bishop Berkeley's reasoning, and yet he admitted the doctrine of fluxions on the authority of sir Isaac's demonstration. That demonstration he then did not pretend to understand; and therefore he admitted the doctrine through prejudice.

We have made these observations to point out the absurdity of the fashionable cry against the harbouring of any prejudices. To eradicate

P R E J U D I C E.

all prejudices from the human mind is impossible; and if it were possible, it would be very unwise: for we see that prejudice may exist on the side of truth as well as on that of falsehood; and that principles professed and believed by any individual may be useful and true, though he were brought to them not by a train of fair and candid reasoning, but through the medium of prepossession or authority. Indeed such is our nature, and such are the laws of association, that many of our best principles, and our obligation to perform many of the most amiable of our duties in common life, must evidently be acquired in this way. From endearing associations, and authoritative instruction, we acquire a knowledge of our duty to our parents, and a facility in performing it, together with the first principles of religion, without a single effort of our own reason. Even when reason has begun to assert its power and shows us the propriety of such duties, we are wonderfully assisted in performing them by the amiable prejudices which we had before acquired, and which now appear to be natural to us. He who has never had the advantage of such associations, and who acquires a knowledge of the duties suggested by them after he has come to years of discretion, and chiefly by the efforts of his own reason, will seldom, *ceteris paribus*, perform these duties with an energy and delight equal to that of the person who has. This remark appears to be confirmed by experience; for it is often found, that the children of the great, who have been given out to nurse in their infancy, and who have seldom been in the company of their parents till their reasoning faculties have been far advanced, are much less dutiful and affectionate than those in the middle or lower stations of life, who have scarcely ever been out of their parents' company.

Would it then be wise, even if it were practicable, to dissolve all those associations which tend so powerfully to increase the mutual affections of parents and children? We cannot think that it would; as we believe it might be easily shown that public spirit springs out of private affection. Plato indeed held an opinion very different from ours; for in order to extend that affection which is usually lavished at home to the whole state, he proposed that children should be educated at the public expense, and never permitted to know the authors of their being. But this is only one of the many visionary projects of that great man, of which daily experience shows the absurdity. In modern times, we are certain that less dependence is to be had upon the patriotism of the man who, for the love which he pretends to his country, can overlook or forget his own partial connections in it, than to him who, at the same time that he wishes his country well, is feelingly alive to all the endearments of kindred affection.

Such affection may be called partial, and very probably has its foundation in that which is the source of all our prejudices: but if it be properly trained in early life, it will gradually

extend from our nearest relations to the persons with whom we associate, and to the place which not only gave us birth, but also furnished our youthful and most innocent enjoyments. It is thus that the *amor patriæ* is generated, which in minds unseduced by false principles is exceedingly strong; and though a partial affection, is of the most general utility. It is this prejudice which reconciles the Laplander to his freezing snows, and the African to his burning sun; which attaches the native of the Highlands or of Wales as much to his mountains and rocks, as the apparently happier inhabitant of the southern counties of England is to the more fertile and delightful spot where he drew his first breath. And we find in fact, that when a native of Kent and a Scotch Highlander have in some distant corner of the world gained a competent fortune without being corrupted by luxury, they return, one to his hop-gardens, and the other to his mountains. Were this prejudice, for such it surely is, wholly eradicated from the human mind, it is obvious that large tracts of country which are now full of inhabitants would be totally deserted; and that the hungry barbarians, to make room for themselves, would exterminate the proprietors of more favourable climes. From an affection to our friends and to our country, we naturally contract an affection for that mode of government under which we live; and unless it be particularly oppressive to ourselves or any order of citizens, we come as naturally to prefer it to all other modes, whether it deserve that preference or not. This no doubt is prejudice, but it is a beneficial prejudice; for were the multitude, who are wholly incapable of estimating the excellencies and defects of the various modes of government, to become dissatisfied with their own, and rise in a mass to change it for the better, the most horrible consequences might justly be dreaded. Of this truth the present state of Europe affords too melancholy and convincing a proof. The man, therefore, who, under the pretence of enlightening the public mind and extirpating prejudices, paints to the illiterate vulgar, in aggravated colours, the abuse of that government which has hitherto protected them from the ferocity of each other, is one of the greatest criminals if his views be selfish, and one of the worst reasoners, if they be disinterested, that human imagination can easily conceive.

With the selfish patriot we have at present no concern, but we may with propriety ask the disinterested lover of truth, whether he thinks it possible, that in a large community, of which nine-tenths of the members are necessarily incapable of taking comprehensive views of things, or feeling the force of political reasonings, any form of government can be acceptable to the people at large, which does not gain their affections through the medium of prejudice? It has been shown by Mr. Hume, with great strength of argument, that government is founded on opinion, which is of two kinds, viz. opinion of interest, and opinion

PREJUDICE.

of right. By opinion of interest, he understands the sense of the general advantage which is reaped from government, together with the persuasion that the particular government which is established is equally advantageous with any other that could easily be settled. The opinion entertained of the right of any government is always founded in its antiquity; and hence arises the passionate regard which under ancient monarchies the people have for the true heir of their royal family. These opinions, as held by the philosopher, conversant with the history of nations, are founded upon reasoning more or less conclusive; but it is obvious, that in the minds of the multitude they can have no other foundation than prejudice. An illiterate clown or mechanic does not see how one form of government promotes the general interest more than another; but he may believe that it does, upon no other evidence than the declamation of a demagogue, who, for selfish purposes, contrives to flatter his pride. The same is the case with respect to the rights of hereditary monarchy. The anatomist finds nothing more in the greatest monarch than in the meanest peasant, and the moralist may perhaps frequently find less; but the true philosopher acknowledges his right to the sovereignty: and though he be weak in understanding, or infirm in years, would, for the sake of public peace and the stability of government, maintain him in his throne against every competitor of the most shining talents. The vulgar, however, who would act with this philosopher, are influenced by no such views, but merely by their prejudices in favour of birth and family; and therefore it is ridiculous to think of changing the public mind with respect to any form of government by pure reasoning.

The influence of prejudice is not more powerful in fixing the political opinions of men, than in dictating their religious creed. Most children of religious fathers receive their faith by inheritance long before they are capable of judging whether it be agreeable or disagreeable to the word of God and the light of reason. This experience shows to be the fact; and sound philosophy declares that it cannot be otherwise. Parents are appointed to judge for their children in their younger years, and to instruct them in what they should believe, and what they should practise in the civil and religious life. This is a dictate of nature, and doubtless would have been so in a state of perfect innocence. It is impossible that children should be capable of judging for themselves before their minds are furnished with a competent number of ideas, and before they are acquainted with any principles and rules of just reasoning; and therefore they can do nothing better than run to their parents, and receive their directions what they should believe and what they should practise.

This mode of tutoring the infant mind, and giving to our instructions the force of prejudice, before reason can operate with much effect, will, we know, be highly displeasing to many

who challenge to themselves alone the epithet of liberal. With them it will be cramping the genius and perverting the judgment: but we cannot help thinking that such an objection, if it should be made, would be the offspring of ignorance; for it requires but very little knowledge of human nature to be able to see, that if children be not restrained by authority, and if we do not insinuate a love of good principles into their minds, bad ones will insinuate themselves, and a little time will give them the force of inveterate prejudice, which all the future efforts of reason and philosophy will find it difficult to eradicate. The idea of keeping a child ignorant of the being of a God, and the grand duties of morality and religion, till he shall come to years of discretion, and then allowing him to reason them for himself, is an absurd chimæra: it is an experiment which never has been tried, which to us it appears impossible to try, and which, if it could be tried, could not possibly produce any good effect. For suppose we had a youth just arrived at years of discretion, totally ignorant of all these things, and unbiassed to any system of opinions, or rather possessed of no opinions at all—it would, in the first place, we suspect, be absolutely necessary to direct his thoughts into a particular train, and for some person to lead him on from one idea to another, till he should arrive at some conclusion: but in all this there is the influence of authority, association, and of prejudice.

It being therefore absolutely necessary that sentiments of religion be instilled into the minds of children, before they be capable of discovering by the use of their reason whether those sentiments be just or not, it need not excite wonder, nor is it any reflection upon religion, that most men adhere with bigotry to the creed of their fathers, and support that creed by arguments which could carry conviction to no minds but their own. The love and veneration which they bear to the memory of those from whom they imbibed their earliest opinions do not permit them to perceive either the falsehood of those opinions, or their little importance supposing them true. Hence the many frivolous disputes which have been carried on among christians; and hence the zeal with which some of them maintain tenets which are at once contrary to scripture, to reason, and to common sense. A due reflection, however, on the source of all prejudices, ought to moderate this zeal; for no man is wholly free from that bias which he is so ready to condemn in others: and indeed a man totally free from prejudice, would be a more unhappy being than the most violent bigot on earth. In science, he would admit nothing which he could not himself demonstrate; in business, he would be perpetually at a stand for want of motives to influence his conduct: he could have no attachment to a particular country; and therefore must be without patriotism, and without the solaces of friendship; and his religion, we are afraid, would be cold and lifeless.

What, it will be said, are the authors of a

PREJUDICE.

work which professes to enlighten the public mind by laying before it a general view of science and literature become at last the advocates of prejudice, which is the bane of science, and the prop of superstition? No, we are advocates for no prejudice which is either inimical to science or friendly to absurdity; but we do not think that the moralist would act wisely who should desert his proper business to make himself master of the higher mathematics, merely that he might not be obliged to trust occasionally to the demonstrations of others. The writer of this article is not skilled in trade; but it is not his opinion that the merchant would soon grow rich, who should never make a bargain till he had previously calculated with mathematical exactness all the probabilities of his gain or loss. That to dissolve all the associations which are the source of partial attachments of kindred, affection, and private friendship, would tend to promote the public happiness, we cannot possibly believe. And we think that the experience of the present eventful day abundantly confirms Mr. Hume's opinion, that far from endeavouring to extirpate the people's prejudices in favour of birth and family, we should cherish such sentiments, as being absolutely requisite to preserve a due subordination in society. That men would be better Christians if they were to receive no religious instruction till they should be able by their own reason to judge of its truth, daily observation does not warrant us to conclude; for we see those who have seldom heard of God when children, "live without him in the world" when they are men.

Pernicious prejudices should be prevented by proper attention in the education of children; and the earlier such attention is paid, the more effectual it will be found; for it is much easier to keep prejudices out of the mind than to remove them after they have been admitted. This, however, must be sometimes attempted; and where prejudices are strong, several methods have been recommended for rendering the attempt successful. The following are taken mostly from Dr. Watts's Improvement of the Mind.

1. Never attack the prejudice directly, but lead the person who is under its influence step by step to the truth. Perhaps your neighbour is under the influence of superstition and bigotry in the simplicity of his soul; you must not immediately run upon him with violence, and show him the absurdity or folly of his own opinions, though you might be able to set them in a glaring light; but you must rather begin at a distance, and establish his assent to some familiar and easy propositions, which have a tendency to refute his mistakes, and to confirm the truth; and then silently observe what impression this makes upon him, and proceed by slow degrees as he is able to bear, and you must carry on the work perhaps at distant seasons of conversation. The tender or diseased eye cannot bear a deluge of light at once.

Overhastiness and vehemence in arguing is oftentimes the effect of pride; it blunts the

poignancy of the argument, breaks its force, and disappoints the end. If you were to convince a person of the falsehood of the doctrine of transubstantiation, and you take up the consecrated bread before him and say, "You may see, and taste, and feel this is nothing but bread; therefore whilst you assert that God commands you to believe it is not bread, you most wickedly accuse God of commanding you to tell a lie." This sort of language would only raise the indignation of the person against you, instead of making any impressions upon him. He will not so much as think at all on the argument you have brought, but he rages at you as a profane wretch, setting up your own sense and reason above sacred authority; so that though what you affirm is a truth of great evidence, yet you lose the benefit of your whole argument by an ill management, and the unreasonable use of it.

2. Where the prejudices of mankind cannot be conquered at once, but will rise up in arms against the evidence of truth, there we must make some allowances, and yield to them for the present, as far as we can safely do it without real injury to truth; and if we would have any success in our endeavours to convince the world, we must practise this complaisance for the benefit of mankind. Take a student who has deeply imbibed the principles of the Peripatetics, and imagines certain immaterial beings, called substantial forms, to inhabit every herb, flower, mineral, metal, fire, water, &c. and to be the spring of all its properties and operations; or take a Platonist, who believes an *anima mundi*, "an universal soul of the world," to pervade all bodies, to act in and by them according to their nature, and indeed to give them their nature and their special powers; perhaps it may be very hard to convince these persons by arguments, and constrain them to yield up those fancies. Well then, let the one believe his universal soul, and the other go on with his notion of substantial forms, and at the same time teach them how by certain original laws of motion, and the various sizes, shapes, and situations of the parts of matter, allowing a continued divine concurrence in and with all, the several appearances in nature may be solved and the variety of effects produced, according to the corpuscular philosophy, improved by Descartes, Mr. Boyle, and sir Isaac Newton; and when they have attained a degree of skill in this science, they will see these airy notions of theirs, these imaginary powers, to be so useless and unnecessary, that they will drop them of their own accord. The Peripatetic forms will vanish from the mind like a dream, and the Platonic soul of the world will expire.

We may give another instance of the same practice, where there is a prejudicate fondness of particular words and phrases. Suppose a man is educated in an unhappy form of speech, whereby he explains some great doctrine of the gospel, and by the means of this phrase he has imbibed a very false idea of that doctrine; yet he is so bigotted to his form of words, that

he imagines if those words are omitted the form is lost. Now, if we cannot possibly persuade him to part with his improper terms, we will indulge them a little, and try to explain them in a scriptural sense, rather than let him go on in his mistaken ideas. A person who has been bred a Papist, knows but little of religion, yet he resolves never to part from the Roman Catholic faith, and is obstinately bent against a change. Now it cannot be unlawful to teach such an one the true Christian, i. e. the Protestant religion, out of the Epistle to the Romans, and show him that the same doctrine is contained in the Catholic Epistles of St. Peter, James, and Jude, and thus let him live and die a good Christian in the belief of the religion taught him out of the New Testament, while he imagines he is a Roman Catholic still, because he finds the doctrine he is taught in the Catholic Epistles, and in that to the Romans. Sometimes we may make use of the very prejudices under which a person labours, in order to convince him of some particular truth, and argue with him upon his own professed principles as though they were true. Suppose a Jew lies sick of a fever, and is forbid flesh by his physician; but hearing that rabbits were provided for the dinner of the family, desired earnestly to eat of them; and suppose he became impatient, because his physician did not permit him, and he insisted upon it that it could do him no hurt—surely rather than let him persist in that fancy and that desire to the danger of his life, we might tell him that these animals were strangled, a sort of food forbidden by the Jewish law, though we ourselves might believe that law to be abolished.

Where we find any person obstinately persisting in a mistake in opposition to all reason, especially if the mistake be very injurious or pernicious, and we know this person will hearken to the sentiment or authority of some favourite name; it is needful sometimes to urge the opinion and authority of that favourite person, since that is likely to be regarded much more than reason. We are almost ashamed indeed to speak of using any influence of authority in reasoning or argument; but in some cases it is better that poor, silly, perverse, obstinate creatures, should be persuaded to judge and act right, by a veneration of the sense of others, than to be left to wander in pernicious errors, and continue deaf to all argument, and blind to all evidence. They are but children of a larger size; and since they persist all their lives in their minority, and reject all true reasoning, surely we may try to persuade them to practise what is for their own interest by such childish reasons as they will hearken to. We may overawe them from pursuing their own ruin by the terrors of a solemn shadow, or allure them by a sugar plum to their own happiness. But after all, we must conclude, that wheresoever it can be done, it is best to remove and root out those prejudices which obstruct the entrance of truth

into the mind, rather than to palliate, humour, or indulge them; and sometimes this must necessarily be done, before you can make a person part with some beloved error, and lead him into better sentiments.

On the whole, we would recommend more mutual forbearance and less acrimony than is commonly found among writers on disputed subjects, as the only means by which our differences in religion, politics, and science, ever can be healed, and truth certainly discovered. If men were less violent in defending their particular opinions, they would always gain a more patient hearing, they would be less suspected of, and less liable to, prejudice, and of course more apt either to convince, or to be convinced. They would likewise by so doing show, in the most unequivocal manner, their attention to sound philosophy, and above all to genuine Christianity; which, though it is far from encouraging scepticism, or a temporizing spirit, recommends, in the strongest terms, among all its professors, universal charity and mutual forbearance. See PROBABILITY, TRUTH, and SUPERSTITION.

TO PREJUDICE. *v. a.* (from the noun.) 1. To prepossess with unexamined opinions; to fill with prejudices (*Prior*). 2. To obstruct or injure by prejudices previously raised (*Whilgift*). 3. To injure; to hurt; to diminish; to impair; to be detrimental to (*Prior*).

PREJUDICIAL. *a.* (*prejudiciable*, Fr.) 1. Obstructed by means of opposite prepossessions (*Holyday*). 2. Contrary; opposite (*Hooker*). 3. Mischievous; hurtful; injurious; detrimental (*Atterbury*).

PREJUDICIALNESS. *s.* (from *prejudicial*.) The state of being prejudicial; mischievousness.

PRELACY. *s.* (from *prelate*.) 1. The dignity or post of a prelate or ecclesiastic of the highest order (*Ayliffe*). 2. Episcopacy; the order of bishops (*Dryden*). 3. Bishops. Collectively (*Hooker*).

PRELATE. *s.* (*prelat*, Fr. *prælatus*, Lat.) An ecclesiastic of the highest order and dignity (*Shakspeare*).

PRELATICAL. *a.* (from *prelate*.) Relating to prelates or prelacy.

PRELATION. *s.* (*prælatus*, Latin.) Preference; setting of one above the other.

PRELATURE. **PRELATURESHIP.** *s.* (*prælatúra*, Latin.) The state or dignity of a prelate.

PRELECTION. *s.* (*prælectio*, Latin.) Reading; lecture; discourse (*Hale*).

PRELIBATION. *s.* (from *prælibo*, Lat.) Taste beforehand; effusion previous to tasting (*More*).

PRELIMINARY. *a.* (*preliminaire*, Fr.) Previous; introductory; proemial (*Dryden*).

PRELIMINARY. *s.* Something previous; preparatory act (*Pope*).

PRELUDE, PRELUDIO, or PRELUDIUM. (From the Lat.) A short introductory composition, or extempore performance, to prepare the ear for the succeeding movements.

PRELUDE denotes, 2. something introductory; something that only shows what is to follow (*Addison*).

To PRELUDE *v. a.* (*preluder*, Fr. *préludo*, Lat.) To serve as an introduction; to be previous to (*Dryden*).

PRELUDIOUS *a.* (from *prelude*.) Previous; introductory (*Cleaveland*).

PRELUDIUM *s.* (Latin.) Prelude (*Dryden*).

PRELUSIVE *a.* (from *prelude*.) Previous; introductory; proemial (*Thomson*).

PREMATURE *a.* (*præmaturus*, Latin.) Ripe too soon; formed before the time; too early; too soon said, or done; too hasty (*Hammond*).

PREMATURELY *ad.* Too early; too soon; with too hasty ripeness.

PREMATURENESS. PREMATUREITY. *s.* (from *premature*.) Too great haste; unreasonable earliness.

To PREMEDITATE *v. a.* (*præmeditor*, Latin.) To contrive or form beforehand; to conceive beforehand (*Dryden*).

To PREMEDITATE *v. n.* To have formed in the mind by previous meditation; to think beforehand (*Hooker*).

PREMEDITATION *s.* (*premeditatio*, Latin.) Act of meditating beforehand (*More*).

To PREMIERIT *v. a.* (*præmereor*, Lat.) To deserve before (*King Charles*).

PREMICES *s.* (*primitiæ*, Latin; *premiées*, French.) First fruits (*Dryden*).

PREMIER *a.* (Fr.) First; chief (*Camden*).

To PREMISE *v. a.* (*præmissus*, Lat.) 1. To explain previously; to lay down premises (*Burnet*). 2. To send before the time: not used (*Shakspeare*).

PREMISES *s.* (*præmissa*, Lat.) 1. Propositions antecedently supposed or proved (*Hooker*). 2. In law language, houses or lands.

PREMISS *s.* (*præmissum*, Latin.) Antecedent proposition (*Watts*).

PREMIUM *s.* (*præmium*, Lat.) Something given to invite a loan or a bargain.

PREMIUM OF ASSURANCE, is the sum of money given to an insurer, or to a company, either annually, or at one or more distant payments, to secure a certain advantage or privilege.

PREMISLAU, a town of Poland, in the palatinate of Lemburg, with a strong castle, and a Greek and Latin bishop's see. It is seated on the river Sana, 60 miles W. by S. of Lemburg. Lon. 21. 0 E. Lat. 49. 0 N.

PREMNA, in botany, a genus of the class didynamia, order angiospermia. Calyx two-lobed; corol four-cleft; seeds solitary. Three species; trees of the East Indies.

To PREMONISH *v. a.* (*præmoneo*, Lat.) To warn or admonish beforehand.

PREMONISHMENT *s.* (from *premonish*.) Previous information (*Wolton*).

PREMONITION *s.* (from *premonish*.) Previous notice; previous intelligence (*Chapman*).

PREMONITORY *a.* (from *præ* and *mones*, Lat.) Previously advising.

To PREMONSTRATE *v. a.* (*præ* and *mones*, Latin.) To show beforehand.

PREMONTVAL (Peter le Guay de), was born at Charenton in 1716, and became a member of the academy at Berlin; at which place he died in 1767, at the age of 51. His best work is his *Preservatifs contre la corruption de la langue Française*, written in German.

PREMUNIRE. See **PRÆMUNIRE**.

PREMUNITION *s.* (from *præmunio*, Lat.) An anticipation of objection.

PRENANTHES. Wild lettuce. In botany, a genus of the class syngenesia, order polygamia equalis. Receptacle naked; calyx invested with scales; down simple, mostly sessile; florets in a single row. Thirty-three species, scattered over the globe; one, *P. muralis*, common to our own groves.

To PRENOMINATE *v. a.* (*præ* and *nominio*, Latin.) To forename (*Shakspeare*).

PRENOMINATION *s.* (*præ* and *nominio*, Latin.) The privilege of being named first (*Brown*).

PRENOTION *s.* (*prenotion*, French.) Foreknowledge; prescience (*Brown*).

PRENTICE *s.* (contracted from *apprentice*.) One bound to a master, in order to instruction in trade (*Shakspeare*).

PRENTICESHIP *s.* (from *prentice*.) The service of an apprentice (*Pope*).

PRONUNCIATION *s.* (*prænuncio*, Lat.) The act of telling before.

PREOCCUPANCY *s.* (from *preoccupate*.) The act of taking possession before another.

To PREOCCUPATE *v. a.* (*preoccupar*, Fr.) 1. To anticipate (*Bacon*). 2. To prepossess; to fill with prejudices (*Wolton*).

PREOCCUPATION *s.* (*preoccupation*, French.) 1. Anticipation. 2. Prepossession. 3. Anticipation of objection (*South*).

To PREOCCUPY *v. a.* To prepossess; to occupy by anticipation or prejudices (*Arbuthnot*).

To PREOMINATE *v. a.* (*præ* and *ominor*, Latin.) To prognosticate; to gather from omens any future event (*Brown*).

PREOPINION *s.* (*præ* and *opinio*, Lat.) Opinion antecedently formed; prepossession (*Brown*).

To PREORDAIN *v. a.* (*præ* and *ordain*.) To ordain beforehand (*Hammond*).

PREORDINANCE *s.* (*præ* and *ordinance*.) Antecedent decree: not in use (*Shakspeare*).

PREORDINATION *s.* (from *preordain*.) The act of preordaining.

PREPARATION *s.* (*præparatio*, Latin; *préparation*, French.) 1. The act of preparing or previously fitting any thing to any purpose (*Wake*). 2. Previous measures (*Burne*). 3. Ceremonious introduction (*Shakspeare*). 4. The act of making or fitting by a regular process (*Arbuthnot*). 5. Any thing made by pro-

PREPARATION.

ness of operation (*Brown*). 6. Accomplishment; qualification: out of use (*Shakspeare*).

PREPARATION OF ANIMALS, and parts of animals: of vegetables and parts of vegetables, for the purpose of preserving them.

This is a very extensive and important subject. It is obviously extensive from its range; and it is of great importance, as it affords the best and most direct mode of conveying instruction, and of communicating a knowledge of natural facts, of which, in thousands of instances, we could never otherwise become eye-witnesses. We shall examine it, therefore, in the order in which we have now noticed it, and shall treat successively of the preservation, first of animal, and secondly of vegetable substances.

I. PREPARATION OF ANIMAL SUBSTANCES.

Of the two distinct branches, this is by far the most momentous; and it has been studied to a certain extent in all ages.

Animals are prepared in such manner that the exterior and entire form may be preserved; or only that particular parts of it, dissected from the rest, may be distinctly and permanently presented to the view. The former method comprises the art of embalming and of preparing animals for cabinets and museums of natural history: the latter comprehends the art of anatomical and zootomical preparations.

Embalming.—This appears first of all to have been practised in Egypt, where it constituted a branch of medical science, and was carried to so high a degree of perfection, that the bodies which were the subjects of it, and which, when duly prepared, were called mummies, have in many instances been preserved to the present day, and have consequently descended through a period of many thousand years. Upon this topic, however, we have already treated, under the word **EMBALMING**, and without encumbering our pages further, shall refer the reader to that article.

Preparation of animals for museums.—The art of chemistry, which is of high importance in the process of embalming, is of equal value in the assistance it affords the naturalist in the preparing quadrupeds, birds, fishes, and other animals, for his cabinet of curiosities. It points out the means not only of giving them duration and consistence, but of continuing to them as long as possible their general appearance in a living state, their natural attitudes, positions, and distinctive characters.

Reaumur will be found to have published a treatise upon this subject, in the *Philosophical Transactions*, vol. XLV. and there is another treatise that at one time was regarded as of considerable consequence in the *Dictionnaire d'Histoire Naturelle*; neither of which, however, are very satisfactory, or capable of leading us to much perfection in this delicate art. The hints thrown forth by Dr. Hunter, and to which we have adverted in the article **EMBALMING**, are of far more importance, and should be studied and put in practice in connection with the directions afforded by the principal writers upon this subject, among whom we may place Kuckham, Chaptal, and Pinel.

Kuckham published a process for the preparation of birds in the *Philosophical Transactions*, vol. LX. His composition to preserve them from putrefaction is a mixture composed of a quarter of a pound of corrosive sublimate; half a pound of

calced saltpetre; a quarter of a pound of calced alum; half a pound of flowers of sulphur; a quarter of a pound of musk; one pound of black pepper; and one pound of pulverised tobacco: these are to be kept mixed together in a well-closed glass vessel, and in a dry place. The corrosive sublimate is an useful ingredient in the preparation of various quadrupeds: but it is fatal to all except the coleopterous or crustaceous insects; and another objection to the entire compound is its expence. On this last account, Pinel recommends the following substitute: equal parts of corrosive sublimate, or arsenic, calced alum, camphor and canella, or any other aromatic: all which are in like manner to be pulverised and mixed together.

Pinel has also strongly recommended the following varnish, which was for a long period kept as a profound secret, and was well known to have been employed with great success, especially in preventing the generation of minute insects in the skins of dead animals, as well as in destroying them if hatched: so that for three or four years, till they can be conveniently placed in the collection for which they are designed, the keeping such preparations under glasses may be dispensed with, and they may be packed up without injury in close cases. It is composed of the following articles: Four ounces of pulverised arsenic are to be put into one pound of brandy, and the mixture is to be gently heated; a quantity of black soap and aloes are then to be added, so as to form a kind of magma, which must be lightly extended while warm in the interior of the animal with a brush, the soft parts having been removed, the same process being applied to the external surface of the skin. When used, however, he recommends it to be diluted with alcohol: and immediately after its use the preparation should be mounted, as the evaporation of the fluid part occasions the skin to become harsh and difficult to soften again.

It is with this magma that cotton or flax ought to be impregnated, with which the internal parts of animal bodies are to be filled; and it is found to be far superior to the mixture composed of a solution of camphor in rectified spirit of wine, which is the preparation commonly used in our own country. It is likewise necessary that the zoologist should be provided with caustic soda, a solution of which corrodes the soft parts, and by uniting with the fat parts forms a species of soap that is afterwards easily taken out by repeated lotions. Chaptal recommends the cranium and intestines, when deprived of their contents, to be syringed with sulphuric ether.

Small animals or parts of large ones are often preserved by being kept in spirit of wine; for which purpose it is remarked by Leonhardi that a little water and a fifth part of spirit of sal ammoniac should be added, which will continue the colour and the softness.

Anatomical preparations.

These consist of viscera in a healthy or a morbid state. We shall notice both in their order.

Preparations of the viscera in a healthy state.—The various parts of the body may be preserved in a healthy state, either to exhibit their form or structure, or to compare them with morbid parts.

When removed from the body, and the useless parts dissected away, the part to be preserved is

P R E P A R A T I O N .

to be soaked in water, in order to get out the blood.

When it is necessary to give parts their natural form, which is lost by macerating; put them into a saturated solution of alum, or rectified spirit, retaining them by any means in the required form until they become hardened. If it be a hollow part, as the stomach, bladder, &c. fill it with, and immerse it in, the solution, or spirit.

When an opening is to be exhibited, as that of the ureter, the bile-duct, the lacunæ of the urethra, Stenonian duct, Fallopian tube, &c. introduce a bristle. After this manner preserve the uterus and its appendages, cutting open the vagina and cavity of the uterus, the bladder, intestine, stomach, heart in the pericardium, liver, spleen, kidney, &c. &c.

All preparations of the brain are best hardened in a saturated solution of corrosive sublimate.

The parts are to be suspended in proof spirit by raw silk, in a tie-over bottle, and covered with putrid bladder, taking care to exclude all air. When dry, varnish the bladder with mucilage of gum arabic several times; then put a sheet of thin lead over, and varnish its edges with mucilage; and, lastly, tie another bladder over, and give it a coat of common spirit varnish, in which lamp-black, or other colouring matter, is mixed, or with Brunswick varnish.

Preparations of morbid parts.—All morbid parts should, immediately after their removal from the body, be put into rectified spirit of wine for a day or two, and then preserved in proof spirit. These preparations foul a great quantity of spirit, and should therefore be kept in stopper-glasses, from which the spirit can easily be removed, and fresh put in, until the preparation ceases to foul the spirit, when it may be put into a tie-over bottle.

Preparations made by macerating.—Preparations obtained by this process are very various.

Let the water be frequently changed, until it is no longer coloured with blood, but never after the blood is steeped away. Let the macerating pan be placed in a warm place, to facilitate putrefaction, for if it be put in a cold place, the spermatic-like conversion of the soft parts will be formed, and the part spoiled. The soft parts surrounding bones are a long time before they detach themselves from the bones. Bones, when macerated, should be exposed to the sun's rays, and frequently wetted with clean water, or they may be bleached with the diluted oxygenated muriatic acid.

Bones are macerated, to be preserved whole; or they are sawed, to expose their internal structure. In preparing the bones of the head, put the whole head, without disturbing the flesh or brains, into the pan. When sufficiently macerated, all the soft parts will come away with the periosteum; then detach the vertebrae, and wash out the brain. Bones are separated from each other by filling the cranium with peas, and putting it into water. The same method is to be adopted with other bones.

In preparing bones in general for structure, divide the femur into two halves: the os innominatum, the petrous portion of the temporal bone, the parietal bone, &c.: these, when macerated, will exhibit the compact, the spongy, laminated, and reticular substance of bones.

Fœtus.—Cut carefully away the fatty substance

enveloping a fœtus, but do not cut any of the cartilages. Steep out its blood, and macerate. It should be frequently looked at, and taken out when the flesh is all destroyed, before the cartilages are separated. The following preparations are obtained in this way:

The superior extremity, to shew its bones, the progress of ossification, and the cartilage to be formed into bone. The lower extremity, to expose the same circumstance. The spine, which forms a beautiful preparation. The pelvis, not less elegant. The mode of preservation is by proof spirit.

The cuticle of the hand and foot may be separated by maceration: the former is called chirotheca, the latter podatheca. The arm and foot of a large fœtus are to be preferred; they are first to be well washed with a soft sponge in soap and water.

Preservation.—Suspend them in proof spirit: first tie the part by which they are to be suspended, then put them into the bottle with the spirit, and gently pour some spirit into the cuticle, to distend it like a glove or stocking.

Injecting instruments.—The celebrated Dutch anatomist, Ruysch, first invented the art of injecting animal bodies; hence it is termed the Ruyschian art.

There are three kinds of apparatus used in making injected preparations. The one for the coarse and fine injections, and the minute injection; the other for injecting with quicksilver; and the third, called the oyster syringe, for injecting minute preparations with the minute injection only.

The first consists of a brass syringe made for the purpose, of various sizes, from one carrying six ounces to one sufficiently large to hold two pounds. The point of these syringes is adapted to the pipes into which it is to be affixed. To this syringe belong a stop-cock, and a great variety of pipes.

The instrument for injecting quicksilver consists of a long glass tube, at whose end is fixed, by screwing in, a steel pipe, the end of which is extremely fine.

The oyster syringe is similar to the large syringe, except in size. It is so small, that when the syringe is in the hand, and full, its piston may be commanded by the thumb of that hand to throw its contents into any preparation in the other hand. The pipe affixed by being screwed to the end of this syringe is nearly as small as that belonging to the quicksilver tube.

These instruments are always to be had at the surgical instrument-makers.

The injections employed for anatomical purposes are of four different kinds: coarse, fine, minute, and mercurial.

Coarse injections.—Red.—Yellow bees' wax, sixteen ounces—the palest resin, eight ounces—turpentine varnish, six ounces, by measure—finely levigated vermilion, three ounces.

Yellow.—Yellow bees' wax, sixteen ounces—pale resin, eight ounces—turpentine varnish, six ounces—king's yellow, two ounces and a half.

White.—Fine virgin wax, sixteen ounces—pale resin, eight ounces—turpentine varnish, six ounces—best flake white, five ounces and a half.

Pale blue.—Fine virgin wax, sixteen ounces—pale resin, eight ounces—turpentine varnish, six ounces—best flake white, three ounces and a half—fine blue smalt, three ounces and a half.

P R E P A R A T I O N.

Dark blue.—Fine virgin wax, sixteen ounces—pale resin, eight ounces—turpentine varnish, six ounces—blue verditer, ten ounces and a half.

Black.—Yellow bees' wax, sixteen ounces—pale resin, eight ounces—turpentine varnish, six ounces—pure lamp-black, one ounce.

Green.—Yellow bees' wax, sixteen ounces—pale resin, eight ounces—turpentine varnish, six ounces—levigated crystallized verdigrise, four ounces and a half—best flake white, one ounce—levigated gamboge, one ounce.

Liquefy the wax, resin, and turpentine varnish over a slow fire, in an earthen pipkin; then add the colouring matter, having previously mixed it in another pipkin, with a very small quantity of the melted composition. Stir the whole well together with a wooden pestle, so that the colouring ingredients may be intimately and smoothly blended; place the whole again over the fire, and, when they have acquired their due heat, the injection will be fit for use.

Fine injections.—Brown spirit varnish, white spirit varnish, of each four ounces—turpentine varnish, one ounce.

These are to be put together in an earthen pipkin, over a slow fire, until they have acquired the necessary degree of heat. To make it of a red colour, put one ounce of finely levigated vermilion into another pipkin, and gradually add the heated materials, stirring the whole with a wooden pestle, that the colour may be equally diffused.

One ounce and a quarter of king's yellow—two ounces of best flake white—one ounce and a half of fine blue smalt, with one ounce and a quarter of best flake white—four ounces of blue verditer—half an ounce of pure lamp-black—are the proportions for the various colours to the quantity of ingredients ordered above.

Minute injections.—The size, which forms the vehicle to the colouring matter in these injections, is made in the following manner:

Take, of the finest and most transparent glue, one pound, break it into small pieces, put it into an earthen pot, and pour on it three pints of cold water; let it stand twenty-four hours, stirring it now and then with a stick; then set it over a slow fire for half an hour, or until all the pieces are perfectly dissolved; skim off the froth from the surface, and strain it through a flannel for use.

Isinglass and the cuttings of parchment make an elegant size for very particular injections; and those who are not very nice may use the best double size of the shops.

Red.—Size, one pint—Chinese vermilion, two ounces.

Yellow.—Size, one pint—king's yellow, two ounces and a half.

White.—Size, one pint—best flake white, three ounces and a half.

Blue.—Size, one pint—fine blue smalt, six ounces.

Green.—Size, one pint—levigated crystallized verdigrise, two ounces—best flake white, levigated gamboge, of each eight scruples.

Black.—Size, one pint—lamp-black, one ounce.

All injections are to be heated to such a degree as not to destroy the texture of the vessels they are intended to fill: the best criterion of this degree of heat is dipping the finger into the injection. If the finger can bear the heat, the texture of the vessels will not be hurt.

All the coloured materials should be as finely levigated as possible, before they are mixed with the injection.

Great care should be taken lest the oily ones boil over, or bubble; and that the heat be gentle, otherwise the colour will be altered. They should be constantly stirred, lest the colouring material, which is much heavier than the vehicle, fall to the bottom. The instrument to stir them with should be a wooden pestle, and there should be one for each colour. A large tin pan to contain water, with two or three lesser ones fixed in it for the injections, will be found very useful, and prevent all accidents, and the colour from spoiling when on the fire.

Preparations made with coarse injection.—The blood-vessels are mostly filled with coarse injection, and the parts dissected, to shew their course; and when the anatomist wishes to exhibit the minuter branches, the fine injection is to be thrown in first, and followed by the coarse.

There are several circumstances to be observed in injecting with the fine and coarse injections, which are applicable to every part into which they are thrown; these are—the part to be injected should be freed from its blood as much as possible, by steeping it for several hours in warm water, and repeatedly changing it. Having emptied the part of its blood, the pipes are to be fixed in their proper vessels, and all other vessels to be tied with a ligature. The heat of the water is then to be gradually increased to the same temperature with the injection to be thrown in. The injecting syringes should be steeped in the water with the part to be injected until wanted. The injection being finished, and the subject cold, remove the pipes and tie up the parts they were in. Whenever a vessel is open, by accident or otherwise, be sure to secure it by a ligature, or cover it with a piece of thin and moist bladder, or the injection will always be oozing out. The parts dissected and dried are to be varnished twice with copal or hard varnish, first washing them free from grease with some soap-lees, and well drying them again.

Blood-vessel subject.—Select an emaciated subject, between the age of two and fourteen years.

Make an incision through the integuments the whole length of the sternum: then, with a saw, divide the sternum longitudinally into two equal parts; introduce a dissecting knife under the divided bone on each side, separate it from the mediastinum, and lay open the thorax, by bending back the two portions of the sternum and the cartilages of the ribs: an incision is then to be made into the pericardium, and the left ventricle of the heart, and a large pipe introduced into the aorta, and secured by a ligature. The subject is next to be put into warm water, and gradually heated. The time generally required to heat the whole subject is four hours, in a large body of water.

If the veins are to be injected, three more pipes are required: one to be put into the angular vein, at the corner of the orbit; another into a vein as near the fingers as possible; and the third into a vein as near to the toes as possible.

The subject and injection being properly heated, throw the coarse red injection into the heart pipe, which will fill the arterial system; and then the coarse yellow injection into the head pipe first, and next into the pipes of the extremities. The subject, when injected, should be put into cold water, with its face downwards.

P R E P A R A T I O N .

Open the abdomen by an incision from the sternum to the umbilicus, and thence to each ilium. Cut away the abdominal viscera, the stomach, spleen, and intestines; leaving the mesenteric vessels as long as possible: dissect away the liver, leaving the vena portæ and hepatic artery as long as possible. This done, dissect away the fat and cellular membrane from the vessels; secure the mesenteric vessels in an arborescent form on a piece of pasteboard. The kidneys, urinary bladder, uterus, and its appendages, are to be preserved and dried in their situations. From the thorax are to be removed the lungs and heart, or the latter may remain. The integuments being carefully dissected from the sternum, it is to be bent back, and kept in that situation, to expose the internal mammary arteries. The dissecting away the skin is next, in order to exhibit the muscles, and expose the arteries and veins. The skin should only be removed from time to time to carry on the dissection, and never more than that covering the part to be dissected; otherwise the parts from which the skin is removed will become dry, and the dissection be spoiled. In dissecting the arteries and veins, the dissector will find no difficulty, if he proceeds cautiously from the larger trunks towards their extremities. The brain is to be removed by sawing away a large portion of the bone on each side of the longitudinal sinus of the dura mater. The cheeks should be pushed out by introducing horse-hair into the mouth.

When dissected, or before, the subject should be hung up by the head in a frame: one arm is to be placed at a little distance from the side, and the other turned up over the head, with the palm of the hand in front: the legs at a little distance from each other, and kept in these postures by pack-thread. Should any muscles obstruct the sight of the arteries, they are to be separated to a proper distance by pieces of wood. This done, expose it to a current of air, in a place where it cannot get wet; and if the weather be moist, remove, from time to time, all moisture, by a soft sponge.

Varnish it several times, and keep it in a dry place, and in a proper case, with a glass front and back.

A head for arteries and veins.—Choose an emaciated head of an adult, separated from the body, by a transverse section, about the sixth or seventh vertebra.

Put a pipe into each carotid, or, what is better, one pipe with a bifurcation: remove a portion of bone over the longitudinal sinus of the dura mater, about the middle of the parietal bones, and secure a pipe in the longitudinal sinus, pointed towards the occiput. Put the head into warm water, to soak, pressing the blood occasionally out of the external and internal jugulars. Then tie up the jugular veins and vertebral arteries, and all the small vessels.

Into the carotids throw the red injection, and the yellow, or dark blue, into the pipe in the sinus of the dura mater. The former will fill the arteries, the latter the veins.

Follow the course of the larger trunks, dissect out the globes of the eyes, and remove with a fine saw the portion of the jaw-bone behind the last molaris, to shew the course of the internal carotids. To prepare the whole head, a portion of the cranium must be removed, by sawing on one side of the longitudinal sinus of the dura mater, from the frontal sinus to the horizontal spine of the occipital bone, and then sawing horizontally above the ear, from one extremity of the former incision to the other.

The dura mater should be removed with a pair of scissors, the brain carefully washed out, and the tentorium and falx preserved. It is better to make a perpendicular section of the head, a little to one side of the sagittal suture, through the nose, foramen magnum, and vertebra; and thus prepare each side. The course of the cervical artery is to be shewn by dissecting away the muscles, &c. from between the transverse processes.

Varnish it several times, and keep it in a glass-case, suspended; or fix it by the neck, and cover it with a glass bell.

An arm, for arteries and veins.—Remove the superior extremity from the trunk, by separating the clavicle from the sternum, raising it, and passing the knife under it to the articulation, including the greater part of the pectoral muscle. Then cut under the scapula, so as to remove with the arm the clavicle, scapula, and subscapularis muscle.

After soaking it in warm water, force out the blood from the veins, by pressing the extremity from the fingers towards the shoulder. Fix a pipe in the axillary artery, and another in the largest vein on the back of the hand; some warm water may be injected into the vein, so as to wash out the blood; and, when pressed out, the axillary vein should be tied. Tie any muscular branches that may be gaping.

Red injection may be thrown into the artery, and yellow, or dark blue, into the vein.

This is very simple; it requires only the removal of all the cellular and fatty membrane, and exposing the course of the vessels. Tie up the limb by the clavicle.

When varnished, keep it in a cool and dry place.

A lower extremity, for arteries and veins.—Having removed the contents of the abdomen, make a section through the symphysis of the pubis, and the ligaments connecting the ilium and sacrum, so as to remove one side of the pelvis.

Fix a pipe in a vein as near the toes as possible, and another in the iliac artery. When the limb has been well soaked in warm water, press out the blood from the veins, or throw in some warm water at the venal pipe; but carefully press it out again, and tie up the iliac vein. Secure all divided vessels.

Blue injection, or yellow, may be put into the vein, and red into the artery.

Expose the course of the artery and veins, particularly the profunda of the thigh.

The gravid uterus, for arteries and veins.—The gravid uterus, or the uterus soon after it has expelled the fœtus, may be injected, to shew its large and tortuous vessels. It may be injected whilst in the body; but this is always attended with much difficulty, and never succeeds so well as when removed from the body. Therefore separate the spermatic and hypogastric vessels as far from the uterus as possible, and cut out the uterus with the bladder, vagina, and external parts of generation.

Put a pipe in each spermatic artery, and each hypogastric, and also one into each spermatic and hypogastric vein; so that, at least, there will be four pipes for arteries, and four for veins, necessary. Be very careful that all the divided vessels be secured by ligature, which only can ensure success.

Red and yellow are mostly preferred; the former for the arteries, the latter for the veins. Be careful that the red be thrown into all the arterial pipes, and the yellow into the venal; and, to prevent mistakes, it will be better to have the pipes of the veins different from those of the arteries.

P R E P A R A T I O N .

Distend the vagina and uterus with horse-hair, either by introducing it through the vagina, or, if the fœtus be in it, by a perpendicular section through the anterior parietes, which is to be sewed up again. Then dissect away all loose cellular structure and fat, preserving the round and broad ligaments, and Fallopian tubes. Should the fœtus be in the uterus, an incision should be made, as above directed, except the placenta be adhering there, which is known by the great number of vessels, and then on the opposite side, and through the membranes, to remove the child; cut the umbilical cord close to the fœtus, and fix a pipe in one umbilical artery, and another in the umbilical vein; the latter carrying arterial blood, should be filled with red injection, and the artery with yellow: the cord is to be laid round the placenta.

When well varnished, suspend it in a case, with a glass front and back.

A placenta, for arteries and veins.—This is perhaps the easiest preparation to make with coarse injection; and should, therefore, be the first attempt of the student.

Fix a large pipe in the vein, and a small one in one of the arteries. The difficulty usually attendant on getting the pipe into the artery is obviated in a great measure by introducing the point of the scissors into these vessels, and slitting them down for about half an inch, then spreading the artery open upon the fore-finger, and keeping it so by pressure with the thumb, by which the pipe may be carried in without difficulty. A ligature should be passed round each pipe with a needle, taking care not to puncture any of the vessels.

The usual colours are to be selected; but instead of throwing the yellow into the vein, it should be pushed into the artery, for the artery here performs the functions of a vein, and *vice versa*. When there are two placenta there should be different colours used.

The spongy substance is to be carefully dissected away from the injected vessels, the placenta soaked in cold water, to get rid of its blood, and then dried, curling the cord around it; and should the membranes not be much torn, they may be distended with curled hair over it.

Varnish it well; fix its bottom in a case with a glass top.

The heart, in situ, with the head, and adjacent vessels.—For this purpose choose the head of a young subject, or an adult, whose heart is free from fat. The liver, stomach, spleen, &c. are to be removed from the abdomen, and the aorta divided just as it gives off the cœliac artery. The incision into the chest should be carried through the integuments, from the trachea to the ensiform cartilage, the sternum sawed through, and bent one half on each side, from the extremity of the cartilages nearest the ribs; then divide one of the pulmonary veins as near as possible to the lungs, and remove a portion of bone over the longitudinal sinus of the dura mater.

Having well soaked the parts in warm water, and squeezed the blood from the heart and vessels, by the inferior cava and pulmonary vein, put a pipe into the longitudinal sinus of the dura mater, pointed towards the occipital bone, another into the pulmonary vein, a third into the vena azygos, and one into the receptaculum chyli, or thoracic duct. Tie up carefully the aorta and the vena cava inferior, and put a strong ligature around the middle of each arm.

Three colours are required:—one for the arteries, which should be red; another for the veins,

which may be yellow or blue; and the third for the thoracic duct, which should be white, to imitate chyle. Throw the red injection into the pipe in the pulmonary vein, which will fill the left auricle, ventricle, aorta, and all the arteries. The pipe in the head is for the yellow injection: by this will be filled the veins of the head, face, neck, and chest, the right auricle of the heart, the right ventricle, and the pulmonary arteries. Should the vena azygos not be injected, the yellow injection is to be thrown into it. A small quantity of white injection is sufficient for the thoracic duct.

Remove the body by a transverse section at the last dorsal vertebra, then amputate the arms at their middle, saw away one side of the bones of the skull, and wash away the brain: then dissect away all the loose cellular membrane and fat, and expose the various parts in the best manner; dissect away the lungs, leaving the pulmonary arteries as long as possible.

This is, when well done, a valuable preparation, and deserving of great care. Varnish it well, and preserve it in a square glass-case.

A fœtus, to exhibit the peculiarities of its circulation.—For this purpose select a still-born fœtus; and, if possible, one that died from a flooding of the mother.

Dissect the umbilical vein from the arteries, about four inches from the umbilicus, and fix a pipe in it, taking care not to include the arteries. Throw warm water into this pipe, and wash out the blood, which will flow out by the umbilical arteries. Having drained away as much of the water as possible, tie a ligature very loose on the umbilical arteries.

The fœtus being heated, throw in gently any coloured injection. The water will come away first through the umbilical arteries; and, when the injection appears, make the ligature firm, to prevent its further egress.

The peculiarities in the fœtal circulation are the umbilical cord, the ductus venosus, the ductus arteriosus, and foramen ovale. When the body is cold, proceed to the dissection; remove the head from the cervical vertebrae, the arms, with the scapulæ, and pectoral muscles; the inferior extremity at the articulation with the pelvis, the whole of the parietes of the abdomen, leaving the arteries running to the cord by the sides of the bladder; the anterior part of the thorax, with the sternum, cartilages, and part of the ribs, the integuments and muscles of the back. Next cut away the lungs, and remove the pericardium; keep the diaphragm in its place, and turn up the liver, so as to expose the ductus venosus. Some discretion and care is here necessary. Dissect away the stomach and intestines, and lay out the mesenteric vessels, distend the bladder with air, and cut away any thing that may obstruct the view of the vessels. The foramen ovale cannot be exhibited.

After having varnished it, hang it in a glass bell, with a hook at its top.

The penis may be injected, to shew the two corpora cavernosa, the corpus spongiosum, and glans, with the arteries and veins. For this purpose any healthy penis will do, but large ones are generally preferred. Having cut through the integuments and soft parts in the pelvis, in the direction the saw is to be passed, saw through the middle of each crista of the pubis, straight down and through the ascending ramus of each ischium, close to their commencement, and thus remove the pubis, with the bladder and external parts of generation.

PREPARATION.

Make an incision into either of the crura of the corpora cavernosa, and into the bulbous part of the urethra, as near to the prostate gland as possible; soak it in hot water, and carefully press out the blood from every part. Introduce a probe along the vena magna ipsius penis, by an incision at its root, to break down its valves; fix a pipe in each of these incisions, and another in each vas deferens, at its entrance into the vesiculæ seminales, and secure all the divided vessels.

Four colours are necessary; those generally preferred are red, yellow, blue, and white. Throw the red into the corpus spongiosum, which will distend the glans; the yellow into the corpus cavernosum pipe; the blue into the vena magna ipsius penis; and the white into the vasa deferentia.

Inflate the bladder, dissect away all the soft parts, and keep the penis erect against the symphysis pubis. Preserve it in a covered box.

A testicle of an adult should be chosen free from disease, and great care is requisite in removing it from the body. First, enlarge the ring of the oblique muscle, push the testicle through from the scrotum, and separate its cellular connecting substance; then cut the spermatic artery and pampiniform plexus as high as possible, and then the vas deferens.

When well soaked, press out the blood from the veins; put a pipe into the spermatic artery, and another into a vein; and secure all other open mouths.

Red is to be sent into the artery, and yellow or blue into the vein, which is without valves. Then fix the quicksilver tube in the vas deferens, and suspend it in water; this done, fill it with mercury, and in twenty-four hours it may be removed to be dissected.

Cut away the tunica vaginalis and the tunica albuginea, which requires great care: then remove all the cellular and adipose membrane, and dry it on a board previously waxed. Preserve it in a common preparation glass, on a blue or green paper ground.

The system of the vena portæ.—Remove the liver, spleen, stomach, and intestines all together, of a person whose mesentery is free from fat, cutting away at the root of the mesentery, behind the peritoneum.

Cut into a mesenteric vein, as near to the intestine as possible, and secure it with a ligature passed around it with a needle, taking care not to wound any other vein. Inject warm water, and let it again run out by the divided vessels. Drain its water off, and secure all the veins, the hæmorrhoidal especially.

Throw any colour into the pipe, which will pass into the splenic, mesenteric, and internal hæmorrhoidal vein, and into the vena portæ.

Remove all the soft parts; the stomach, spleen, and intestines; cutting the vessels as long as possible, and dry them in the best manner, either attached to the liver, or dissect away the liver from the vena portæ, taking care to preserve some of its ramifications. Preserve the preparation in a covered box.

The heart is mostly injected out of the body, to shew its common and proper vessels. For this purpose, choose a lean heart. Cut through the thoracic viscera immediately at the top of the thorax; divide the intercostal arteries by drawing the knife down the pleura, over the ribs beyond their origin; separate the vena cava inferior and aorta, in the abdomen, with the cavæ hepaticæ;

and remove the thoracic viscera, with the portion of the diaphragm surrounding the vessels.

Soak the blood and coagula out of the cavities of the heart, and press the blood from the coronaries. Put a pipe into the vena cava superior, and another into one of the pulmonary veins. Then tie the lungs at their root, the vena cava inferior, the arteria innominata, the left carotid and subclavian; and pass a ligature, with a slip knot, round the sinus of the aorta, and secure all other open vessels.

The common coloured injections, red and yellow, only are wanted. Throw the former into the pulmonary vein, which will fill the left auricle, ventricle, aorta, and coronary arteries. The yellow, being sent into the superior cava, will distend the right auricle, coronary veins, right ventricle, and pulmonary artery. In order to fill the coronaries well, the injector must stop two or three times in the course of the process, to squeeze on the injection in them with his nail; then heat the whole again, and throw in more injection. The preparation having cooled, a pipe is to be fixed at the bottom of the aorta, and some red injection, just hot enough to run through the syringe, is to be pushed along the aorta, an assistant throwing cold water on the intercostals, if the injection runs through them.

Cut away the lungs, pericardium, and all the soft parts. Preserve it either in a covered box, or under a glass bell.

Stomach. Intestines. Bladder.—These are best injected with the whole subject, but may be removed and injected separately.

The anatomist can only succeed by having the preparation constantly heated as he is throwing in the injection.

The injection should be thrown in very gradually.

When injected, the part should be immediately immersed in cold water.

Preparations with minute injection.—The vascularity of bones is to be demonstrated, by throwing fine injection into an extremity, cutting out the bone when cold, separating it from all the soft parts, immersing it in water for a few days, to soak out the blood, and then putting it into a mixture of muriatic acid and water in the proportion of one ounce to a quart, for three or four months, adding about, every month, a drachm of acid. The limb of a rickety child is to be chosen.

Put a pipe into the largest artery of the extremity, and throw gradually the red injection into it, fixing the stop-cock in the pipe.

Still-born children, when injected with minute injection, afford a number of beautiful preparations.

No water should be thrown into the vessels. Fix a pipe with a stop-cock into the umbilical vein, and tie the arteries in the ligature.

Red injection is always chosen for this purpose; and throw it in with great care, until the abdomen and skin all over become very tumid. First mucus comes from the nose and mouth, then the meconium from the anus, and often pure size.

Cut off the head from the shoulders, the arms below the shoulder joint, and the legs just below the acetabulum; then preserve a small quantity of the integuments around the navel, and remove all the anterior parietes of the abdomen and chest, so as to exhibit the thoracic and abdominal viscera. Cut away the integuments and posterior part of the theca vertebralis, to exhibit the medulla spinalis.

PREPARATION.

Soak out the blood, and preserve it in proof spirit, to shew the viscera and their vascularity.

From a well-injected fœtus may be obtained the following preparations:

If the fœtus be about seven months old, the membrana pupillaris.

If it be male of this age, the testicle in the abdomen, with the gubernaculum.

The vascular and radiated fibres of the parietal bones.

The vascular membrane, including the teeth.

The viscera of the chest separate, if better injected than those of the abdomen, shewing the vascularity of the lungs, thymus gland, and heart.

The stomach, which is to be inverted, to shew its vascular villous coat.

The intestines, which are to be separated from the mesentery, and inverted, to shew their villous coat.

The glandulæ renales and kidneys together, to exhibit their relative size, and the lobulated structure of the kidney.

The uterus and its appendages, to shew the long ovaria and plicæ of the neck of the uterus and vagina.

The external parts of the female organs of generation, to shew the hymen.

A red portion of the skin, to exhibit its vascularity.

The medulla spinalis, to shew its vessels, and the cauda equina.

The membrana tympani, to exhibit its vascularity.

The cavity of the tympanum, to shew its vascularity, and that of the periosteum of its bones.

The vestibulum and cochlea, to shew the membranous semicircular canals of the former, with their ampullæ injected, and the vascularity of the zona mollis.

The head, to shew the natural appearance of the face, the papillæ of the lips, tongue, &c.

The hand, to shew its natural colour.

The above preparations are all to be well soaked from their blood, and preserved in proof spirit of wine.

A portion of skin, freed of its adeps, to shew its vascularity.

The membrana tympani, to shew its vessels.

The heart, to shew the foramen ovale, by distending the cavities with air; and, when dry, cutting away the outermost sides of the auricles, and introducing a bristle.

Any large muscle, freed from its cellular membrane and fat, and dried, to shew the vascularity of the muscle.

These are all to be dried, well varnished, and preserved in bottles. Some prefer putting them into spirit of turpentine; but this should be avoided as much as possible, for the turpentine is always oozing in warm weather, and dirtying the glass.

The object of injecting a uterus with fine injection is to exhibit the vascularity of its internal membrane, which furnishes the catamenia. For this purpose the uterus of a person whose menstruation has not been stopped by age or disease is to be selected.

Remove the uterus, by dividing the vessels as long as possible, the round and broad ligaments, and as much as possible of the vagina. Tie a pipe in each hypogastric artery, and secure all the divided vessels.

Any coloured injection may be chosen, but red looks best.

Cut away all the loose cellular membrane, bladder, and rectum, if there be any, from around the vagina, and cut it open along the middle of its superior part; continue this incision on each side of the anterior part of the uterus, so as to exhibit the posterior surface of its cavity.

If the injection be successful, which it seldom is more than one time in ten, suspend it by the ligaments, and preserve it in proof spirit.

An adult head.—Separate the head as low as the last cervical vertebra from the shoulders.

Put a bifurcated pipe into the carotids. Secure the vertebral arteries and jugular veins, and all the divided parts. The red injection is always preferred.

From an adult head injected in this way may be made the following preparations:

The upper eyelid, to shew the vascularity of Meibomius's glands. The choroid membrane, exhibiting its vascularity. The retina, suspended by the optic nerve, exhibiting its vascularity. A section of the optic nerve, to exhibit the central artery. The whole of the cerebrum, cerebellum, and medulla oblongata, with the pia mater; or, the pia mater, separated from the convolutions of the brain, to exhibit the intergyral processes and the tomentum cerebri. One half of the nostrils, to exhibit the vascularity of Schneider's membrane, and that of the membrane lining the antrum of Highmore. The tongue, lying in the jaw, and suspended by the palatum molle, with the posterior fauces cut away, to shew the epiglottis and glottis, the uvula and velum pendulum palati, the tongue, its papillæ and excretory ducts, and the vascularity of the gums and sublingual glands.

The above preparations are to be soaked well in cold water, to get out all the blood, and then preserved in proof spirit.

Preparations with quicksilver.—Mercury cannot be coloured by any substances; it must, therefore, always present the same silver colour.

The parts should always be injected in a proper tray, that the mercury may be easily collected. A lancet, with a curved needle ready threaded, should be always at hand; and likewise, a bottle, whose neck is not so wide as to permit the quicksilver tube going to the bottom, when put into it. When injecting, if any circumstance render it necessary for the injector to put aside the tube with the mercury, it should be placed in the bottle, the mercury remaining in it, to be handy and prevent delay. Injecting with mercury is always tedious, and frequently unsuccessful. The parts exposed must be kept moist, by sprinkling them with cold water.

To inject the lymphatics of an arm, choose one from a dropsical subject, without fat; make an incision into the skin around the wrist, and seek diligently with a magnifying-glass, for an absorbent, into which the pipe is to be put, when the quicksilver will immediately run. The shoulder should now be placed considerably lower than the hand; and, when the mercury runs out at the divided vessels in the axilla, tie them up, and also the lymphatic, into which the pipe was introduced. Then seek for another absorbent. When the mercury ceases to run in a lymphatic, tie the vessel, and seek for another.

Begin at the lymphatics, where the mercury entered, and trace them; removing every thing that obstructs their view, but preserve the glands.

An inferior extremity for this purpose should also be taken from a dropsical person, and the

P R E P A R A T I O N .

same method adopted as with the superior extremity, seeking as near to the toes as possible for the lymphatics.

A parotid gland.—Cut down upon the masseter muscle, and seek for the Stenonian duct, which is the excretory duct of the parotid. Tie the quicksilver pipe in it, then fix the tube, and pour into it the quicksilver; and, when it ceases to run, remove the tube and pipe, and tie the duct. Be particularly careful, in dissecting away the gland, not to cut it.

Dry it on a waxed board, and preserve it on a blue paper and pasteboard, in spirit of turpentine.

The lymphatics running on the peritoneal coat of the liver, and over the gall-bladder, make a beautiful preparation. The liver should be well soaked for several days, and the pipe put into the lymphatics of the suspensory and coronary ligaments, and the mercury forced along them, breaking down the valves with the nail, by pressing on the mercury. Secure the vessels at the portæ of the liver, when the mercury gets there, and tie the lymphatics when filled. Should the anatomist's attempt to force the quicksilver beyond the valves be unsuccessful, he must fix upon the most minute obvious branch, and let it run its proper course.

Throw some coarse injection into the cavæ hepaticæ and vena portæ, without heating the liver thoroughly; inflate the gall-bladder, and dry the whole. Varnish it, and preserve it in the best manner under a glass bell, or preserve the injected part in proof spirit, without any wax injection.

The superficial lymphatics of the lungs are to be filled from the part most remote from the root of the lungs.

Cut away the part on which the lymphatics are filled. Dry it on a waxed board, varnish it, and preserve it in a bottle, on a green or blue piece of paper; or preserve it in proof spirit, without drying it.

Hand.—Select the hand of an aged female (separated from the arm by a transverse section, three inches above the wrist) that has died of a lingering disease. Soak out the blood in warm water; fix the pipe in the radial artery, then add the tube, and pour into it the mercury. As the mercury appears in the other arteries and veins, take them up and secure them with ligatures. Should the mercury still escape from small branches, put a cord round the arm, and with a piece of wood tighten it, by twisting the wood, taking care not to prevent the mercury passing into the hand. Then suspend the hand in a glass filled with water, and suspend also the tube and quicksilver in the manner represented in the annexed plate, for a day or two, that the mercury may get into the small vessels. When injected, remove the pipe, and tie, by a strong string, the fore-arm; put the hand into water, until putrefaction separates the cuticle.

Dry it carefully, and varnish it; then fix the fore-arm in a pedestal of plaster of Paris, and keep this beautiful preparation under a glass bell.

Lacteals.—Remove the mesentery and intestines, if the former be perfectly free from fat, and let them remain several days in water, which should be frequently changed. Search for an absorbent, on the intestine, into which introduce the quicksilver, which will run on to the glands in the mesentery, where it will stop. When the lacteals are filled, the preparation will be more elegant if

red and yellow coarse injection be thrown into the mesenteric arteries and veins.

Spread the mesentery on a waxed board, inflate a portion of the intestine, clear away all that is useless; dry and varnish, and preserve it in a glass frame.

Corroded preparations.—These preparations are made by filling the vessels with coarse injection, and corroding the soft parts, so as to exhibit those vessels.

The liquor for corrosion is to consist of three parts of muriatic acid, and one of water. The liquor should be kept in a well-glazed earthen vessel, with a top to it, also well glazed. The part to be corroded should be carefully moved in and out of this liquor, as the slightest force may break the vessels. When corroded, the pulpy flesh is to be carefully washed away, by placing it under a cock of water, the water flowing very slowly; or, in some instances, by squirting it away. When the preparation is freed of its flesh, it should be fixed in the situation it is to remain in, either in a plaster of Paris pedestal, or on a flat surface. If the flesh be not perfectly destroyed, the preparation is to be returned to the corroding liquor for a fortnight or month longer, or until it becomes pulpy.

Heart and lungs.—These viscera, occupying less space in children than adults, are to be preferred. It is of no consequence whether they are fat or lean. The integuments should be cut from the fore part of the neck; and the trachea, jugular veins, and carotid arteries removed, and, with them, the viscera of the thorax, carefully separating the subclavian vessels from the clavicle, without injuring them, and dividing the axillary vessels and the cava inferior and aorta, just below the diaphragm.

Soak the whole well, to free it of its blood, and press out all the fluids: fix a pipe in the inferior cava, and another in one of the pulmonary veins, taking care not to injure the others, by tying it. Then secure the carotids, the jugulars, the axillary vessels, the vertebral artery, the intercostals, the aorta, after it has formed its arch, the internal mammaries, and every vessel that can be found.

Red and yellow are generally preferred, but red and blue are more proper, and more elegant. Throw the blue into the vena cava inferior, which will distend the right auricle, the superior cava, the jugular veins, and great coronary vein, the right ventricle, and pulmonary arteries. The red injection will fill the left auricle and pulmonary veins, the aorta, subclavians, carotids, &c.

Great care is requisite in freeing the injection from the pulpy flesh. When done, let the apex of the heart be placed immediately in a plaster of Paris pedestal, and cover it with a glass. If the pulmonary vessels are well preserved, it forms a valuable preparation. If one good preparation be obtained in ten trials, it will amply repay the anatomist.

Heart.—A fat heart will do for this purpose. Inject it as directed in the article *heart, in situ*, three pages back, and put it into the corroding liquor. Lay it on some cotton, on a pedestal, and cover it with a glass.

Liver.—The liver of a child is to be preferred to that of an adult, it occupying much less room: its vessels should be cut long, and with it the portion of the duodenum, perforated by the bile duct.

Fix a pipe into the hepatic artery, another into

the vena portæ, a third into the ductus communis choledochus, and a fourth in the vena cava hepatica. The four injections are the red, yellow, dark blue, and light blue. First, throw the red injection into the hepatic artery, next the dark blue into the vena portæ, then the light blue into the cava hepaticæ, and lastly, the yellow into the ductus communis choledochus. Remove the pipes as soon as the injection will permit; and, when corroded, fix the trunks in the best manner possible, upon a proper pedestal; then wash away the flesh, dry it, and cover it with a glass.

Kidney.—Choose the kidney of an old drunkard. Cut the emulgent vessels close to the aorta and cava, and the ureter, very low; then remove the kidney, with all its surrounding adeps.

Soak out the blood, and press out all the fluid. Fix a pipe in the emulgent artery, another in the vein, and a third in the ureter; and tie up all the open-mouthed vessels.

Red, blue, and yellow. First throw the yellow into the vein, then the red into the artery, and lastly, the blue into the ureter.

Preserve under a glass bell. The kidneys of different animals form a beautiful exhibition.

It hence appears then, in few words, that the manner of preserving anatomical preparations is either by drying them thoroughly in the air, or putting them into a proper liquor. In drying parts which are thick, when the weather is warm, care must be taken to prevent putrefaction, flyblows, insects, &c. This is easily done by the use of a solution of corrosive sublimate in spirit of wine, in the proportion of two drams of sublimate to a pound of spirit: the part should be moistened with this liquor as it dries, and by this method the body of a child may be kept safe even in summer. Dried preparations are apt to crack and moulder away in keeping; to prevent this, their surface should be covered with a thick varnish, repeated as often as occasion requires.

Though several parts prepared dry are useful, yet others must be so managed as to be always flexible, and nearer a natural state. The difficulty has been to find a proper liquor for this purpose. Dr. Monro says, the best he knows is a well rectified colourless spirit of wine, to which is added a small quantity of the spirit of vitriol or nitre. When these are properly mixed, they neither change their colour nor the consistence of the parts, except where there are serous or mucous liquors contained in them. The brain, even of a young child, in this mixture grows so firm as to admit of gentle handling, as do also the vitreous and crystalline humours of the eye. The liquor of the sebaceous glands and the semen are coagulated by this spirituous mixture; and it heightens the red colour of the injection of the blood-vessels, so that after the part has been in it a little time, several vessels appear which were before invisible. If you will compare these effects with what Ruysch has said of his balsam, you will find the liquor above-mentioned to come very near to it.

The proportion of the two spirits must be changed according to the part prepared. For the brain and humours of the eye, you must put two drams of spirit of nitre to one pound of spirit of wine. In preserving other parts which are harder, 30 or 40 drops of the acid will be sufficient; a larger quantity will make bones flexible, and even dissolve them.

Dr. Christ. Jac. Trew prefers the rectified spirit of grain for preserving anatomical preparations to

spirit of wine, or to compositions of alcohol, amber, camphor, &c. because these soon change into a brown colour, whereas the spirit from malt preserves its limpid appearance. When any part is to be preserved wet, wash it with water till it is no more tinged. The water is next to be washed away with spirits, and then the preparation is to be put among spirits in a glass, the mouth of which is to be closely covered with a glass head, over which a wet bladder and leaf-tin are to be tied. Com. Lit. Norimb. 1731, semest. 1 specim. 9. See also Pole's Anatomical Instructor, and American Transactions, vol. ii. p. 366.

II. PREPARATION OF VEGETABLES.

This is of as essential consequence to a thorough knowledge of botany, as the preparation of animals is to a thorough knowledge of zoology or anatomy. The plant or part of a plant in this process is first carefully dried, and then pasted into blank books of sufficient magnitude for their reception without being cramped. The volumes thus filled are denominated a *HORTUS SICCUS*; and as we have described the method of drying plants and pasting them into volumes under that name, we shall refer the reader to the article which it contains.

PREPARATION OF DISCORDS. See MUSIC.

PREPARATIONS, in pharmacy, the medicines when mixed together in such a manner as to be fit for the use of the patient. See PHARMACY.

PREPARATIVE. a. (*preparatif*, French.) Having the power of preparing, qualifying, or fitting (*South*).

PREPARATIVE. s. (*preparatif*, French.) 1. That which has the power of preparing or previously fitting (*Decay of Piety*). 2. That which is done in order to something else (*King Charles*).

PREPARATIVELY. ad. (from *preparative*.) Previously; by way of preparation (*Hale*).

PREPARATORY. a. (*preparatoire*, Fr.) 1. Antecedently necessary (*Tillotson*). 2. Introductory; previous; antecedent (*Hale*).

To PREPARE. v. a. (*præparo*, Lat.) 1. To fit for any thing; to adjust to any use; to make ready for any purpose (*Blackmore*). 2. To qualify for any purpose (*Addison*). 3. To make ready beforehand (*Milton*). 4. To form; to make (*Psalms*). 5. To make by regular process; as, he prepared a medicine.

To PREPARE. v. n. 1. To take previous measures (*Peacham*). 2. To make every thing ready; to put things in order (*Shakspeare*). 3. To make one's self ready; to put himself in a state of expectation.

PREPARE. s. (from the verb.) Preparation; previous measures: not in use (*Shakspeare*).

PREPAREDLY. ad. (from *prepared*.) By proper precedent measures (*Shakspeare*).

PREPAREDNESS. s. (from *prepare*.) State or act of being prepared.

PREPARER. s. (from *prepare*.) 1. One that prepares; one that previously fits (*Wotton*). 2. That which fits for any thing (*Mortimer*).

PREPENSE. **PREPENSED.** *a.* (*præpensus*, Lat.) Fore-thought; preconceived; contrived beforehand: as, *malice prepense*.

To PREPONDER. *v. a.* (from *preponderate*.) To outweigh: not used (*Wotton*).

PREPONDERANCE. **PREPONDERANCY.** *s.* (from *preponderate*.) The state of outweighing; superiority of weight (*Locke*).

To PREPONDERATE. *v. a.* (*prepondero*, Latin.) 1. To outweigh; to overpower by weight (*Glanville*). 2. To overpower by stronger influence.

To PREPONDERATE. *v. n.* 1. To exceed in weight (*Bentley*). 2. To exceed in influence or power analogous to weight (*Locke*).

PREPONDERATION. *s.* (from *preponderate*.) The act or state of outweighing any thing (*Watts*).

To PREPOSE. *v. a.* (*proposer*, Fr.) To put before.

PREPOSITION. *s.* (*preposition*, Fr. *præpositio*, Lat.) In grammar, a particle governing a case. See **GRAMMAR**.

PREPOSITOR. *s.* (*præpositor*, Latin.) A scholar appointed by the master to overlook the rest.

To PREPOSSESS. *v. a.* (*pre* and *possess*.) To fill with an opinion unexamined; to prejudice (*Wiseman*).

PREPOSSESSION. *s.* (from *prepossess*.) 1. Preoccupation; first possession (*Hammond*). 2. Prejudice; preconceived opinion.

PREPOSTEROUS. *a.* (*præposterus*, Lat.) 1. Having that first which ought to be last (*Woodward*). 2. Wrong; absurd; perverted (*Denham*). 3. Applied to persons: foolish; absurd (*Shakspeare*).

PREPOSTEROUSLY. *ad.* In a wrong situation; absurdly (*Bentley*).

PREPOSTEROUNESS. *s.* (from *preposterous*.) Absurdity; wrong order or method.

PREPOTENCY. *s.* (*præpotentia*, Latin.) Superiour power; predominance (*Brown*).

PREPUCE. *s.* (*præputium*, Latin.) That which covers the glans; foreskin. See **ANATOMY**.

To PRE REQUIRE. *v. a.* (*pre* and *require*.) To demand previously (*Hammond*).

PREREQUISITE. *a.* (*pre* and *requisite*.) Previously necessary (*Hale*).

PREROGATIVE. *s.* (*prerogatif*, French.) An exclusive or peculiar privilege (*Sidney*).

PREROGATIVE (Royal), in law, means all the rights and privileges which by law the king hath, as chief of the commonwealth, and as intrusted with the execution of the laws; and this can be only according to magna charta. We shall here briefly set down those articles which are enumerated by lord chief baron Comyns, in his Digest, as belonging to the king's prerogative, premising only, that many things are laid down in our law-books from ancient authorities, which do not thoroughly accord with the spirit of the constitution, as improved at the revolution; and that every thing which is contrary to that glorious spirit may be well

questioned to be law at the present day. Those who were formerly called prerogative lawyers were little better than the willing slaves of absolute monarchy.

As to his domestic concerns, the care of the marriages in the royal family belongs to the king, and is now regulated by statute 12 George III. c. 11.

As to foreign nations, he has the sovereignty of the seas surrounding England, and may make treaties and alliances, and send ambassadors and envoys to foreign states, and a league is said to be broken by a prohibition of all the commodities of a kingdom in amity. He may, in virtue of the same right, grant reprisals, by taking the goods of foreign subjects, here or elsewhere, and he is entitled to all prizes; but, by certain acts called the prize-acts, they are distributed in certain shares amongst the captors, according to a proclamation to be made in every new war, and 5l. a head is allowed to ships of war for every man killed. The king may also grant letters of safe conduct to an enemy here; and without these, it is said, a foreign prince, though in amity, cannot come here.

With respect to the king's own subjects, he has the sole authority to declare war or peace, and to levy soldiers, and by 11 Henry VII. c. 1. and 18, every man is bound to serve the king in his wars, but not out of the realm, except for wages; nor can he be sent out of the kingdom even with an office. In like manner, the right of impressing seamen is acknowledged; but it must not be exercised wantonly, as by taking a captain of a merchantman to serve as a common man, and, by 13 George II. c. 17, persons of fifty-five years of age, and under eighteen, and every person going to sea for two years, and every apprentice during three years, are exempted; and also all foreigners; besides which there are other particular exemptions; nor are mariners, except deserters, to be impressed in the West Indies. He has also the sole command of the forces, as well militia as regulars, and that, by 13 Charles II. c. 6, independent of the houses of parliament. His troops may be billeted all over the kingdom; and no one but the king can build forts.

With respect to time of peace, he enacts laws, together with his parliament; but cannot by grant or charter alter the law. He may issue proclamations to enforce laws; and by 1 James, c. 25, and 12 Charles II. 4, s. 12; may restrain the transportation of corn, and gunpowder, arms, and ammunition, generally, or from particular places. By statute 31 Henry VIII. since repealed, he might, in effect, make new laws by his proclamation. But now he cannot suspend the execution of a law for any time, as till the meeting of the next parliament. It is said, that the king may dispense with a thing prohibited, so as to make it lawful, in case of necessity, to the party to do the prohibited thing; but dispensations are odious, and, indeed, except under the following limitations, the king's dispensing power may now

P R E R O G A T I V E .

be questioned. As, however, he may grant a pardon when the offence is committed, it seems not of so much importance. He may unquestionably dispense with any thing which is for his benefit, as a penalty due to the king; but not with a thing *malum in se*, nor in which the subject has an interest. He may grant a pardon of all offences, as well in the ecclesiastical as the criminal court; but cannot reverse a judgment without process.

With respect to things ecclesiastical, he has jurisdiction in all ecclesiastical causes, is head of the church, and may punish and repress heresies and superstitions, by statute 37 Henry VIII. c. 17. And ecclesiastical laws, which consist of ancient synods, and canons, and constitutions, and customs, formed with the assent of the king, without the parliament, are of legal authority in England, and, it is said, he may dispense with those laws. He may, with his commissioners, pass ecclesiastical censure, and shall have the ordering of all ecclesiastical appeals, without appeal to the pope. The highest appeal, by statute 25 Henry VIII. c. 19, is to the king, in chancery, who issues a commission to his delegates; but where the king is concerned; it is to the upper house of convocation; and although the appeal to the delegates is final, yet the king may grant a commission of review.

The king's prerogative, as to temporal jurisdiction, enables him to make what courts he pleases, for the administration of the common law, and where he pleases; but he cannot erect a court of chancery, or conscience, the common law being the birthright of the subject. The king may also grant such commissions as are warranted or allowed by the common or statute law, as of oyer and terminer, &c.; but, it is said, he cannot grant a commission of inquiry only, without a clause to hear and determine. He may grant franchises also, because all franchises and liberties are derived from him, as a county palatine, or jurisdiction temporal, or ecclesiastical.

As to nobility and honour, the king is the fountain of all dignity, and may, it is said, compel all persons of 20l. per annum inheritance to be knights, or persons named to be sergeants to take the degree.

The king may also grant privileges, such as those of a forest, chase, warren, park, fair, market, with tolls, or casual profits, as wreck, waifs, strays, deodands, treasuretrove, royal fish, mines, derelict lands, most of which belong to the king, together with certain privileges in trade, for which see TRADE. So he may grant exemptions from those charges which, by his grant, he may impose, as to be quit of toll for merchandise, in every town in England, and to be exempt from offices under the crown, such as that of constable, provided there be a sufficient number to serve; but he cannot grant an exemption from the jurisdiction of any court, if he does not erect a jurisdiction of the same nature in lieu of it, for that would create a failure of justice; nor to be

exempt from punishment from felony or trespass. He may also by proclamation or special writ, directed to the party, or to the sheriff, restrain any person from quitting the kingdom, and may, for reasons of state, lay an embargo upon a ship. So he may inhibit a public nuisance. He may also recalc, by summons, a subject who goes out of the kingdom with or without licence, and if he returns not, upon service of summons, then his lands and goods are forfeited. But, it is said, merchants may abide beyond sea, and a king, in amity, need not deliver up those who fly to him.

The king may, by his prerogative, command mayors and corporate officers to restrain annoyances, and keep streets clean; but not in places which are no corporations; and cannot inhibit a lawful occupation, such as making cards, under pretence of inconvenience, nor restrain the exercise of foot-ball, cock-fighting, or other vain sports, except, perhaps, on Sundays.

As to offices, the king has the nomination of all public officers within the kingdom; but he cannot create a new office with a fee, nor appoint an old office with a new fee, to burthen the public, without his parliament.

As to trade, he may erect societies for the management of it; but cannot grant an embargo on ships, for the benefit of a private trader or company.

As to matters of revenue, the king can alone coin money within his dominions, upon which the duties are now settled, as in statute 18 Charles II.; but the aid, for knighthood, marriage, &c. are taken away by statute 12 Charles II. c. 24.

With respect to purveyance, he may dig for saltpetre in the lands, stables, and other places of a subject; but not where he cannot leave the place in the same plight as before. He must leave room for the horses, &c. of the person, and not dig at improper times, nor return there for a long time, nor can he grant it to another, and the saltpetre must be used for the defence of the realm only, and the subject is at liberty still to dig in his own soil. But he cannot claim any other necessities, such as timber, wood, fuel, cattle, grain, hay, victuals, carts, carriages, &c. without the consent of the owner, by statute 12 Charles II. c. 24.

The customs upon merchandise exported and imported are the ancient inheritance of the crown, which, it is said, were originally by act of parliament; they were distinguished into *customa magna, et parva*, to which were added prisage, or a duty of two tons out of every ship laden with twenty tons of wine; and butlerage, or a levy of 2s. per ton, for every ton of wine of a merchant stranger. The citizens of London were exempt from this duty in the port of London. These duties, it seems, are now repealed by statute 27 George III. c. 13, called the consolidation act, which affixes a certain rate to the commodities therein enumerated, and 27l. 10s. per cent. with a drawback of 25l. per cent. on exportation, upon every other commodity. We have, how-

P R E R O G A T I V E .

ever, read in the public prints during this year, (1807) of the claim of prisage being made in Ireland, by one of the grantees of the crown, and allowed; but we presume, so heavy a tax, if it can be claimed, in addition to the duty on wines, must be repealed by parliament. Customs are not paid where the king has granted goods of a pirate to a patentee, for the king shall not pay custom to himself; and it is said, the king may grant to an alien to pay no more customs than a subject; but this must be subject to the consolidation act.

The king may, by his prerogative, charge an imposition upon the subject for his benefit, as he may grant a certain rate for things sold in a town, for the walls of the town, or repairing the bridge, or the security of those parts. Or that a man may build a wall, or keep a ferry, and take toll for the support of it. But he cannot charge the subject where he has no benefit from it, or a *quid pro quo*, nor levy new customs, &c. Nor can the merchants, by their consent, grant to the king a tax upon their goods, for their wares would thereby be sold the dearer. Upon all which we must observe that it should appear this branch of the prerogative is fallen into disuse, and can scarcely now be claimed as being altogether inconsistent with the spirit of the revolution in 1688. And we now see that in all cases where a pier is to be built, or a turnpike-road made, or improvements are made in cities, application is had to parliament, and a bill is passed. This, it is true, may be partly, because it is often necessary to borrow large sums of money, and to purchase lands by compulsion, &c.; but we still may venture to question this prerogative, although we find it in books of great authority previously to the reigns of Charles the First and Second.

As to casual profits, the king is entitled to all goods which have no owner, as, wreck, flotsan, jetsan, and ligan, waifs, strays, goods of felons, deadlands, treasure-troves, escheats, and lands forfeited. He is entitled also to royal mines, and the fishery of every navigable river, as high as the sea flows: but every one may fish in the sea of a common-right, although foreign nations cannot fish in the British Seas, without the king's licence. There are also certain fines, upon legal proceedings, which the king claims by his prerogative; and anciently, a fine was paid for liberty to have right and justice, which is now abolished by *magna charta* 29, *nulli vendemus*, &c. So fines for beau pleader, for grants of liberties, and for misdemeanors, with all americiaments which are levied by the sheriff and estreated into the exchequer.

All the lands in the kingdom, it is said, are holden mediately, or immediately, of the king, who has no superior; and this is the foundation of the law of forfeiture and escheats: but this, however in practice it may be harmless, is a principle rather derived from the divine right of kings, than the spirit of the revolution, which considers the king rather as deriv-

ing every thing from the people, and holding the throne itself in trust.

Whatsoever lands, or tenements, the king has, belong to him in right of his crown, and are called the sacred patrimony, or demesnes of the crown, says lord Coke; and whether lands descend, or are devised, or given to him and his heirs by statute, or otherwise, they go as parcel of the crown. The king, therefore, it seems, cannot divest himself of his public character, but has all his real possessions, for it does not seem to extend to money, merely as king.

All conveyances to the king ought to be, by deed, enrolled; and where a subject would not have possession without entry, there the king has it not without office found, or other record. But if the king's title is so found upon an inquisition, he is in possession without seizure; and where a common person cannot enter without an action, there the king ought to have a *scire facias*. But no office is necessary where the king's title appears by other matter of record, and where he is so seised he can never be ejected, or disseised; but every one who enters upon his possessions is called an intruder; the remedy upon which is by an information of intrusion. The remedy against the king is by petition to the king in parliament, in chancery, or some other court, for there can be no writ, because the king cannot command himself as it is quaintly expressed. There is also another proceeding by *monstrance de droit*, which is, where the suitor's title appears by the same record as that of the king. Even upon an office found there may now be, by statute 34 Edward III. c. 14, a traverse, denial, or litigation of it.

The king, by his prerogative, may sue in what court he pleases, and shall not be prejudiced by any neglect to pursue his right, which is meant by the maxim *nulium tempus*, &c. or no time runs against the king. Though now, by statute 9 George III. c. 16, the king's suit, except for liberties and franchises, is limited, under certain conditions, to 60 years for lands.

As to the disposal of the personal revenue of the king, this can only be by the great, or privy seal; and every one who receives money out of the exchequer, without due warrant, is accountable for it. He may, it is said, dispose of his lands and other real revenues of inheritance, by patent, to others, when he pleases. And by statute 1 Anne 7, s. 5, all grants by the king of any manors, lands, &c. advowsons of churches and vicarages excepted, shall be void, except for 31 years or under, or for three lives, &c. subject to waste, and at the usual rent or more, or if no usual rent, then a rent at least one-third of the annual value. By the same act, the hereditary excise, revenue of the post-office, first fruits and tenths, fines for writs of covenant, and entry at the alienation office, post fines, wine licences, sheriffs profers, and compositions, and seizures for unaccustomed and prohibited goods, shall not be alienable for

longer than the life of the king who grants them.

It is to be observed that much of the king's prerogative, producing revenue, has been from time to time granted out with various manors; and the article of forfeitures, which might in some cases be somewhat profitable, is very little enforced. When a forfeiture is discovered, the officers of the crown generally allow a portion to the informer; sometimes one-sixth. It has been proposed, by Mr. Bentham, to make forfeitures of land supply, in some measure, the place of taxes, and to restrain the power of bequest of land to certain degrees of kindred only. Blackstone and others, however, though they approve of the statute of Anne to prevent the improperly granting away crown lands, consider the great diminution of the landed demesnes of the crown well exchanged by the subject for the lighter burthen of taxes, since, had things remained as at the conquest, the king would, by forfeiture and otherwise, have possessed all the land in the kingdom. The observation is short-sighted enough, for no people would have tolerated it. William possessed all the lands by force, only to parcel them out like a robber among his troops; and had he not speedily parted with them, he and they must have found that he who grasps all loses all. See REVENUE.

PREROGATIVE COURT, the court wherein all wills are proved, and all administrations taken, which belong to the archbishop by his prerogative; that is, in cases where the deceased had goods of any considerable value out of the diocese wherein he died; and that value is ordinarily 5*l.* except it be otherwise, by composition, between the archbishop and some other bishop, as in the diocese of London, it is 10*l.*

PREROGATIVED. *a.* (from *prerogative*.) Having an exclusive privilege (*Shakspeare*).

PRESAGE. *s.* (*presage*, French; *præsigium*, Lat.) Prognostic; presension of futurity (*Addison*).

To **PRESAGE.** *v. n.* (*presager*, French; *præsigio*, Latin.) 1. To forebode; to foreknow; to foretel; to prophesy (*Milton*). 2. To foretoken; to foreshow (*Shakspeare*).

PRESAGEMENT. *s.* (from *presage*.) 1. Forebodement; presension (*Wotton*). 2. Foretoken (*Brown*).

PRESBURG, the capital of the kingdom of Lower Hungary, called by the inhabitants Posony and Presporen, situated on the Danube, about 46 miles east from Vienna, and 75 from Buda. The castle, in which the regalia are kept, stands on a hill above the town. Here the states assemble; and in the cathedral, dedicated to St. Martin, the king is crowned. The town is not very large, nor well built; but is very ancient, pleasantly situated, and enjoys a good air. Its fortifications are only a double wall and ditch. In the lower suburbs is a hill, where the king, after his coronation, goes on horseback, and brandishes St. Stephen's

sword towards the four cardinal points, intimating, that he will defend his country against all its enemies. Besides the cathedral, there are several other Popish and one Lutheran church, with a Jesuits college, three convents, and two hospitals. It gives name to a county; and is the residence of the archbishop of Gran, who is primate, chief secretary, and chancellor of the kingdom, *legatus natus* of the Papacy, and prince of the holy Roman empire. Lon. 17. 30 E. Lat. 48. 20 N.

PRESBYOPIA. (*πρεσβυωπια*, from *πρεσβυς*, old, and *ως*, sight; because it is frequent with old men.) That defect of the sight by which objects close are seen confusedly, but at remoter distances, distinctly. As the myopia is common to infants, so the presbyopia is a malady common to the aged. The proximate cause is a tardy adunation into the focus, so that it falls beyond the retina. The species are, 1. Presbyopia from a flatness of the cornea. By so much the cornea is flatter, so much the less and more tardy it refranges the rays into the focus. This evil arises, 1st, from a want of aqueous or vitreous humour, which is common to the aged; or may arise from some disease; 2d, from a cicatrix, which diminishes the convexity of the cornea; 3d, from a natural conformation of the cornea. 2. Presbyopia from too flat a crystalline lens. This evil is most common to the aged, or it may happen from a wasting of the crystalline lens. 3. Presbyopia from too small density of the cornea or humours of the eye. By so much more these humours are thin or rarified, so much the less they refrange the rays of light. Whosoever is a myops from this cause is cured in older age; for age induces to a greater density of the cornea and lens. From this it is an observed fact, that the presbyopes are often cured spontaneously, and throw away their glasses, which younger persons in this disease are obliged to use. 4. Presbyopia from a custom of viewing continually remote objects; hence artificers who are occupied in remote objects are said to contract this malady. The reason of this phenomenon is not very clear. 5. Presbyopia senilis. From a multitude of causes aged persons are presbyopes; from a penury of humours, which render the cornea and lens flatter, and the bulb shorter. When in senile age, from dryness, the bulb of the eye becomes flatter and shorter, and the cornea flatter, those who were short-sighted or myopes before, see now without their concave glasses. 6. Presbyopia from too close a proximity of objects. The focus is shorter of distant, but longer of nearer objects. 7. Presbyopia from a coarctated pupil. By so much smaller is the aperture of the diaphragm in an optic tube, so much remoter is the focus. 8. Presbyopia mercurialis, which arises from the use of mercurial preparations. The patient feels a pressing pain in the eye, which, from being touched is increased, and the bulb of the eye appears as if rigid, and with difficulty can be moved. Near objects the patient can scarce distinguish, and distant only

in a confused manner. Many have supposed this disorder an imperfect amaurosis.

PRESBYTÆ, persons who are afflicted with the disorder of the sight called presbyopia. See the preceding article.

PRESBYTER, a priest, or person in priest's orders. He is thus called from the Greek *πρεσβύτερος*, elder; of *πρεσβυς*, old; because, anciently, none were ordained but such as were advanced in years.

The great dispute between the retainers to the Geneva and the Roman discipline is, about the sameness or difference of presbyters and bishops, in the times of the apostles.

Those who consult Acts xx. 17, 28. Phil. i. 1. Tit. i. 5. 7. and 1 Tim. iii. 1. may perhaps be led to conclude, that these titles were applied to the same persons.

The learned bishop Usher expressly says, "I have ever declared my opinion to be, that *episcopus et presbyter gradu tantum differunt, non ordine*; and consequently, that in places where bishops cannot be had, the ordination by presbyters stands valid." And being asked by his majesty at the Isle of Wight, "Whether he found in antiquity, that presbyters alone ordained any?" he replied, "Yes; and that he could shew his majesty more; even where presbyters alone successively ordained bishops;" and instanced in Jerom's words (*Epist. ad Evagrium*) of the presbyters of Alexandria choosing and making their own bishops from the days of Mark, till Heraclius and Dionysius. Baxter's Life, p. 206.

This was the constant sense of our first reformers, Cranmer, Pilkington, Jewel, Grindal, Whitgift, Bancroft, &c. Bishop Burnet expressly says, "As for the notion of distinct offices of bishop and presbyter, I confess, it is not so clear to me; and therefore since I look upon the sacramental actions as the highest of sacred performances, I cannot but acknowledge those who are empowered for them must be of the highest office in the church." Vind. of the Church of Scotland, pa. 336. See **BTSHOP**.

PRESBYTERIAL. PRESBYTERIAN. a. (*πρεσβυτερικόν*.) Consisting of elders; a term for a modern form of ecclesiastical government (*Holyday. King Charles*).

PRESBYTERIANS, a denomination comprehending a very considerable number of persons in Great Britain; but very differently applied in England and Scotland. The English presbyterians do not materially differ from the independents with regard to church-government and discipline, and mode of worship; but they generally allow a much greater latitude of religious sentiments and communion in their churches. The appellation, in this restricted use of it, implies no attachment to the authority of synods, presbyteries, or ecclesiastical assemblies composed of deputies from different churches, any more than to episcopacy and the ecclesiastical hierarchy; and, therefore, according to its original use, it is improperly applied to many who are now distinguished by

it, and who form a very respectable class of nonconformists, or protestant dissenters in this kingdom. See **INDEPENDENTS**.

But the presbyterians, properly so called, that is, those of the established church of Scotland, maintain that the government of the church appointed in the New Testament was by presbyteries, that is, by associations of ministers and ruling elders, possessed all of equal powers, without any superiority among them either in office or in order.

The presbyterians believe, that the authority of their ministers to preach the gospel, to administer the sacraments of baptism and the Lord's supper, and to feed the flock of Christ, is derived from the Holy Ghost by the imposition of the hands of the presbytery; and they oppose the independent scheme of the common rights of Christians by the same arguments which are used for that purpose by the episcopalians (see **EPISCOPACY**). They affirm, however, that there is no order in the church as established by Christ and his apostles superior to that of presbyters; that all ministers, being ambassadors of Christ, are equal by their commission; that presbyter and bishop, though different words, are of the same import; and that prelacy was gradually established upon the primitive practice of making the moderator or speaker of the presbytery a permanent officer.

These positions they maintain against the episcopalians by a great variety of arguments, and tenets of scripture.

The presbyterians of Scotland say that their church is formed upon the primitive model. Her mode of worship, say they, is simple and solemn; her established faith agreeable to the confessions of most other protestant churches; her judicatories are calculated to maintain the rights of the people; and her pastors are men of liberal minds. We cannot therefore more properly continue this article than with a short view of her constitution.

No one is ignorant, that from the first dawn of reformation in Scotland, till the era of the revolution, there was a perpetual struggle between the court and the people for the establishment of an episcopal or a presbyterian form of church government. The former model of ecclesiastical polity was patronised by the house of Stuart on account of the support which it gave to the prerogatives of the crown; the latter was the favourite of the majority of the people, perhaps not so much on account of its superior claim to apostolical institution, as because the laity are mixed with the clergy in church judicatories, and the two orders, which under episcopacy are kept so distinct, incorporated, as it were, into one body. In the Scottish church, every regulation of public worship, every act of discipline, and ever ecclesiastical censure, which in other churches flows from the authority of a diocesan bishop, or from a convocation of the clergy, is the joint work of a certain number of clergymen and laymen acting together with equal authority, and de-

PRESBYTERIANS.

ending every question by a plurality of voices. The laymen who thus form an essential part of the ecclesiastical courts of Scotland, are called ruling elders; and hold the same office, as well as the same name, with those brethren who joined with the apostles and elders at Jerusalem in determining the important question concerning the necessity of imposing upon the Gentile converts the ritual observances of the law of Moses. These lay-elders Paul enjoined Timothy to account worthy of double honour, if they should rule well, and discharge the duties for which they were separated from the multitude of their brethren. In the church of Scotland every parish has two or three of those lay-elders, who are grave and serious persons chosen from among the heads of families, of known orthodoxy and steady adherence to the worship, discipline, and government of the church. Being solemnly engaged to use their utmost endeavours for the suppression of vice and the cherishing of piety and virtue, and to exercise discipline faithfully and diligently, the minister, in the presence of the congregation, sets them apart to their office by solemn prayer; and concludes the ceremony, which is sometimes called ordination, with exhorting both elders and people to their respective duties.

The kirk-sessions, which is the lowest ecclesiastical judicatory, consists of the minister and those elders of the congregation. The minister is *ex officio* moderator, but has no negative voice over the decision of the session; nor indeed has he a right to vote at all, unless when the voices of the elders are equal and opposite. He may indeed enter his protest against their sentence, if he think it improper, and appeal to the judgment of the presbytery; but this privilege belongs equally to every elder, as well as to every person who may believe himself aggrieved by the proceedings of the session. The deacons, whose proper office it is to take care of the poor, may be present in every session, and offer their counsel on all questions that come before it; but, except in what relates to the distribution of alms, they have no decisive vote with the minister and elders.

The next judicatory is the presbytery, which consists of all the pastors within a certain district, and one ruling elder from each parish commissioned by his brethren to represent, in conjunction with the minister, the session of that parish. The presbytery treats of such matters as concern the particular churches within its limits; as the examination, admission, ordination, and censuring of ministers; the licensing of probationers, rebuking of gross or contumacious sinners, the directing of the sentence of excommunication, the deciding upon references and appeals from kirk-sessions, resolving cases of conscience, explaining difficulties in doctrine or discipline; and censuring, according to the word of God, any heresy, or erroneous doctrine which hath been either publicly or privately maintained within the bounds of its jurisdiction. One part of the

constitution of the church of Scotland gives an equal vote, in questions of heresy, to an illiterate mechanic and his enlightened pastor. This has been the source of trouble to many a clergyman; who, from the laudable desire of explaining the scriptures and declaring to his flock all the counsel of God, has employed a variety of expressions of the same import, to illustrate those articles of faith which may be obscurely expressed in the established standards. The fact however is, that, in presbyteries, the only prerogatives which the pastors have over the ruling elders, are the power of ordination by imposition of hands, and the privilege of having the moderator chosen from their body.

From the judgment of the presbytery there lies an appeal to the provincial synod, which ordinarily meets twice in the year, and exercises over the presbyteries within the province a jurisdiction similar to that which is vested in each presbytery over the several kirk-sessions within its bounds. Of these synods there are in the church of Scotland fifteen, which are composed of the members of the several presbyteries within the respective provinces which give names to the synods.

The highest authority in the church of Scotland is the general assembly, which consists of a certain number of ministers and ruling elders delegated from each presbytery, and of commissioners from the universities and royal boroughs. A presbytery in which there are fewer than twelve parishes, sends to the general assembly two ministers and one ruling elder; if it contain between 12 and 18 ministers, it sends three of these, and one ruling elder; if it contain between 18 and 24 ministers, it sends four ministers and two ruling elders; and of 24 ministers, when it contains so many, it sends five, with two ruling elders. Every royal borough sends one ruling elder, and Edinburgh two; whose election must be attested by the kirk-sessions of their respective boroughs. Every university sends one commissioner from its own body. The commissioners are chosen annually six weeks before the meeting of the assembly; and the ruling elders are often men of the first eminence in the kingdom for rank and talents. In this assembly, which meets once a year, the king presides by his commissioner, who is always a nobleman; but he has no voice in their deliberations. The order of their proceedings is regular, though sometimes the number of members creates a confusion, which the moderator, who is chosen from among the ministers, to be as it were the speaker of the house, has not sufficient authority to prevent. Appeals are brought from all the other ecclesiastical courts in Scotland to the general assembly; and in questions purely religious no appeal lies from its determinations.—In the subordination of these assemblies, parochial, presbyterial, provincial, and national, the less unto the greater, consist the external order, strength, and steadfastness of the church of Scotland.

PRESBYTERY, *s.* (from *presbyter*.)

Body of elders, whether priests or laymen (*Cleveland*).

PRESCIENCE. *s.* (*prescience*, Fr.) Foreknowledge; knowledge of future things (*Sou.*).

PRESCIENT. *a.* (*præsciens*, Lat.) Foreknowledge; prophetic (*Bacon*).

PRESCIOUS. *a.* (*præsciens*, Lat.) Having foreknowledge (*Dryden*).

To PRESCIND. *v. a.* (*præscindo*, Latin.)

To cut off; to abstract (*Norris*).

PRESCINDENT. *a.* (*præscindens*, Lat.) Abstracting (*Cheyne*).

To PRESCRIBE. *v. a.* (*præscribo*, Lat.)

1. To set down authoritatively; to order; to direct (*Hooker*). 2. To direct medically (*Swift*).

To PRESCRIBE. *v. n.* 1. To influence by long custom (*Brown*). 2. To influence arbitrarily (*Locke*). 3. (*prescrire*, Fr.) To form a custom which has the force of law (*Arbuthnot*). 4. To write medical directions and forms of medicine (*Pope*).

PRESCRIPT. *a.* (*præscriptus*, Latin.) Directed; accurately laid down in a precept (*Hooker*).

PRESCRIPT. *s.* (*præscriptum*, Latin.) 1. Direction; precept; model prescribed (*Milton*). 2. Medical order (*Fell*).

PRESCRIPTION. *s.* (*præscriptio*, Lat.) 1. Rules produced and authorized by long custom; custom continued till it has the force of law (*South*). 2. Medical receipt (*Temple*).

PRESEANCE. *s.* (*preseance*, Fr.) Priority of place in sitting: not used (*Carew*).

PRESENCE. *s.* (*presence*, Fr. *præsentia*, Latin.) 1. State of being present; contrary to absence (*Shakspeare*). 2. Approach face to face to a great personage (*Daniel*). 3. State of being in the view of a superiour (*Milton*). 4. A number assembled before a great person (*Shakspeare*). 5. Port; air; mien; demeanour (*Collier*). 6. Room in which a prince shows himself to his court (*Spenser*). 7. Readiness at need; quickness at expedients (*Waller*). 8. The person of a superiour (*Milton*).

PRESENCE-CHAMBER. PRESENCE-ROOM. *s.* (*presence and chamber or room*.) The room in which a great person receives company (*Addison*).

PRESENTION. *s.* (*præsentio*, Lat.) Perception beforehand (*Brown*).

PRESENT. *a.* (*present*, Fr. *præsens*, Lat.)

1. Not absent; being face to face; being at hand (*Taylor*). 2. Not past; not future (*Prior*). 3. Ready at hand; quick in emergencies (*L'Estrange*). 4. Favourably attentive; not neglectful; propitious (*Ben Jonson*). 5. Unforgotten; not neglected (*Watts*). 6. Not abstracted; not absent of mind; attentive. 7. Being now in view; being now under consideration (*Law*).

The PRESENT. An elliptical expression for the present time; the time now existing (*Rowe*).

At PRESENT. (*à present*, Fr.) At the present time; now (*Addison*).

PRESENT. *s.* (*present*, French.) 1. A gift;
VOL. IX.

a donative; something ceremoniously given (*Shakspeare*). 2. A letter or mandate exhibited (*Shakspeare*).

To PRESENT. *v. a.* (*præsento*, low Latin.)

1. To place in the presence of a superior (*Milton*). 2. To exhibit to view or notice (*Shakspeare*). 3. To offer; to exhibit (*Milton*). 4. To give formally and ceremoniously (*Prior*). 5. To put into the hands of another (*Dryden*). 6. To favour with gifts (*Dryden*). 7. To prefer to ecclesiastical benefices (*Atterbury*). 8. To offer openly (*Hayward*). 9. To introduce by something exhibited to the view or notice: not in use (*Spenser*). 10. To lay before a court of judicature, as an object of inquiry (*Swift*). 11. To point a missile weapon before it is discharged.

PRESENTABLE. *a.* (from *present*.) What may be presented (*Ayliffe*).

PRESENTA'NEOUS. *a.* (*præsentaneus*, Lat.) Ready; quick; immediate (*Harvey*).

PRESENTA'TION. *s.* (*presentation*, Fr.)

1. The act of presenting (*Hooker*). 2. The act of offering any one to an ecclesiastical benefice (*Hale*). 3. Exhibition (*Dryden*).

PRESENTATION, in law, the act of a patron offering his clerk to be instituted in a benefice of his gift, the same being void. All persons that have ability to make a purchase or grant may also present to vacant benefices in their gift; though where a clergyman is patron of a church, he cannot present himself, but may pray to be admitted by the bishop, and the admission shall be effectual. An infant of any age may also present in his own name; but a presentation by a feme covert must be in the name of both husband and wife. As coparceners make but one patron, they are either to present jointly, or the eldest may present first, and the rest in their turn. Joint-tenants must also join in a presentation; and when a corporation presents, it must be under their common seal. Aliens born and papists cannot present to benefices, which are presented to by the universities; but a popish recusant may grant his patronage to another, who may present where there is no fraud. A patron may revoke his presentation before institution, but not afterwards; and a right of presenting to the next avoidance of a church, whether granted by will or deed, will pass; but a presentation whilst the church is full is judged void.

PRESENTATIVE. *a.* (from *present*.) Such as that presentations may be made of it (*Spel.*).

PRESENTE'E. *s.* (from *présenté*, Fr.) One presented to a benefice (*Ayliffe*).

PRESENTER. *s.* (from *present*.) One that presents (*L'Estrange*).

PRESENTIAL. *a.* (from *present*.) Supposing actual presence (*Norris*).

PRESENTIA'LITY. *s.* (from *presential*.) State of being present (*South*).

To PRESENTIATE. *v. a.* (from *present*.) To make present (*Grew*).

PRESENTIFIC. *a.* (*præsens and facio*, Latin.) Making present: not in use.

PRESENTIFICALLY. *ad.* (from *presen-*
SS

tific.) In such a manner as to make present (*More*).

PRESENTLY. *ad.* (from *present.*) 1. At present; at this time; now (*Sidney*). 2. Immediately; soon after (*South*).

PRESENTMENT. *s.* (from *present.*) 1. The act of presenting (*Shakspeare*). 2. Any thing presented or exhibited; representation (*Milton*).

PRESENTMENT, in law. See **PROSECUTION.** A presentment, generally taken, is a very comprehensive term; including not only presentments properly so called, but also inquisitions of office, and indictments by a grand jury. A presentment, properly speaking, is the notice taken by a grand jury of any offence from their own knowledge or observation, without any bill of indictment laid before them at the suit of the king: as the presentment of a nuisance, a libel, and the like; upon which the officer of the court must afterwards frame an indictment, before the party presented can be put to answer it. An inquisition of office is the act of a jury, summoned by the proper officer to inquire of matters relating to the crown, upon evidence laid before them. Some of these are in themselves convictions, and cannot afterwards be traversed or denied; and therefore the inquest, or jury, ought to hear all that can be alleged on both sides. Of this nature are all inquisitions of *felo de se*; of flight in persons accused of felony; of deodands, and the like; and presentments of petty offences in the sheriff's tourn or court leet, whereupon the presiding officer may set a fine. Other inquisitions may be afterwards traversed and examined; as particularly the coroner's inquisition of the death of a man, when it finds any one guilty of homicide; for in such cases the offender so presented must be arraigned upon this inquisition, and may dispute the truth of it; which brings it to a kind of indictment, the most usual and effectual means of prosecution. See **INDICTMENT.**

PRESENTNESS. *s.* (from *present.*) Presence of mind; quickness at emergencies (*Clarendon*).

PRESERVATION. *s.* (from *preserve.*) The act of preserving; care to preserve (*Davies*).

PRESERVATIVE. *s.* (*preservatif*, Fr.) That which has the power of preserving; something preventive (*Hooker*).

To PRESERVE. *v. a.* (*preservo*, low Lat.) 1. To save; to defend from destruction or any evil; to keep (*Clarendon*). 2. To season fruits and other vegetables with sugar, and in other proper pickles: as, to preserve plums, walnuts, and cucumbers.

PRESERVE. *s.* (from the verb.) Fruit preserved whole in sugar (*Mortimer*).

PRESERVER. *s.* (from *preserve.*) 1. One who preserves; one who keeps from ruin or mischief (*Addison*). 2. He who makes preserves of fruit.

To PRESIDE. *v. n.* (from *præsidio*, Lat. *presider*, Fr.) To be set over; to have authority over (*Dryden*).

PRESIDENCY. *s.* (*presidence*, Fr. from *president.*) Superintendence (*Ray*).

PRESIDENT. *s.* (*præsidents*, Lat.) 1. One placed with authority over others; one at the head of others (*Watts*). 2. Governour; prefect (*Brerewood*). 3. A tutelar power (*Waller*).

PRESIDENT, an officer created or elected to preside over a company, in contradistinction to the other members, who are called residents.

The lord president of the council is the fourth great officer of the crown, as ancient as king John, when he was stiled conciliarius capitalis. His office is to attend on the king, propose business at the council table, and report the transactions there to the king.

The lord president of the court of session in Scotland is the first of the fifteen lords who presides in that august assembly, which is the supreme court of justice in that kingdom.

PRESIDENTSHIP. *s.* (from *president.*) The office and place of president (*Hooker*).

PRESIDIAL. *a.* (*præsidium*, Lat.) Relating to a garrison.

To PRESS. *v. a.* (*presser*, French.) 1. To squeeze; to crush (*Milton*). 2. To distress; to crush with calamities (*Shakspeare*). 3. To constrain; to compel; to urge by necessity (*Hooker*). 4. To impose by constraint (*Dryden*). 5. To drive by violence (*Shakspeare*). 6. To affect strongly (*Acts*). 7. To enforce; to inculcate with argument or importunity (*Felton*). 8. To urge; to bear strongly on (*Boyle*). 9. To compress; to hug (*Pope*). 10. To act upon with weight (*Dryden*). 11. To make earnest (*Bacon*). 12. To force into military service (*Shakspeare*).

To PRESS. *v. n.* 1. To act with compulsive violence; to urge; to distress (*Tillotson*). 2. To go forward with violence to any object (*Knolles*). 3. To make invasion; to encroach (*Pope*). 4. To crowd; to throng (*Mark*). 5. To come unseasonably or importunately (*Dryden*). 6. To urge with vehemence and importunity (*Bacon*). 7. To act upon or influence (*Addison*). 8. To Press upon. To invade; to push against (*Pope*).

PRESS. *s.* (*pressoir*, Fr. from the verb.) 1. The instrument by which any thing is crushed or squeezed; a wine press, a cider press (*Haggar*). 2. The instrument by which books are printed (*Shakspeare*). 3. Crowd; tumult; throng (*Hooker*). 4. Violent tendency (*Shakspeare*). 5. A kind of wooden case or frame for clothes and other uses (*Shakspeare*). 6. A communication to force men into military service (*Raleigh*).

PRESS, in the mechanic arts, a machine made of iron or wood, serving to squeeze or compress any body very close. The ordinary presses consist of six members, or pieces, viz. two flat smooth planks, between which the things to be pressed are laid; two screws or worms, fastened to the lower plank, and passing through two holes in the upper; and two nuts, in form of an S, serving to drive the upper plank, which is moveable, against the lower, which is stable, and without motion.

P R E S S.

Press used by inlayers, resembles the joiner's press, except that the pieces of wood are thicker, and that only one of them is moveable; the other, which is in form of a tressel, being sustained by two legs or pillars, jointed into it at each end. This press serves them for sawing and cleaving the pieces of wood required in marquetry or inlaid work.

Press (Founder's), is a strong square frame, consisting of four pieces of wood firmly joined together with tenons, &c. This press is of various sizes, according to the sizes of the moulds; two of them are required to each mould, at the two extremes whereof they are placed; so as that, by driving wooden wedges between the mould and the sides of the presses, the two parts of the mould wherein the metal is to be run may be pressed close together.

Press (Printing). See **PRINTING-PRESS**.

Press (Rolling), is a machine used for the taking off prints from copper plates. It is much less complete than that of the letter-printers. See its description and use under the article **ROLLING-PRESS PRINTING**.

Press, in coining, is one of the machines used in striking of money, differing from the balance in that it has only one iron bar to give it motion, and press the moulds or coins: it is not charged with lead at its extremes, nor drawn by cordage. See **COINING**.

Press (Binder's cutting), is a machine used equally by bookbinders, stationers, and paste-board-makers; consisting of two large pieces of wood, in form of cheeks, connected by two strong wooden screws, which, being turned by an iron bar, draw together, or set asunder, the cheeks, as much as is necessary for the putting in the books or paper to be cut. The cheeks are placed lengthwise on a wooden stand, in the form of a chest, into which the cuttings fall. Aside of the cheeks are two pieces of wood, of the same length with the screws, serving to direct the cheeks, and prevent their opening unequally. Upon the cheeks the plough moves, to which the cutting-knife is fastened by a screw; which has its key, to dismount it on occasion to be sharpened.

The plough consists of several parts; among the rest a wooden screw or worm, which, catching within the nuts of the two feet that sustain it on the cheeks, brings the knife to the book or paper which is fastened in the press between two boards. This screw, which is pretty long, has two directories, which resemble those of the screws of the press. To make the plough slide square and even on the cheeks, so that the knife may make an equal paring, that foot of the plough where the knife is not fixed slides in a kind of groove, fastened along one of the cheeks. Lastly, the knife is a piece of steel six or seven inches long, flat, thin, and sharp, terminating at one end in a point, like that of a sword, and at the other in a square form, which serves to fasten it to the plough. See **BOOKBINDING**.

As the long knives used by us in the cutting

of books or paper are apt to jump in the cutting thick books, the Dutch are said to use circular knives with an edge all round, which not only cut more steadily, but last longer without grinding.

Press, in the woollen manufactory, is a large wooden machine, serving to press cloths, serges, ratchens, &c. thereby to render them smooth and even, and to give them a gloss. This machine consists of several members; the principal whereof are the cheeks, the nut, and the worm or screw, accompanied with its bar, which serves to turn it round, and make it descend perpendicularly on the middle of a thick wooden plank, under which the stuffs to be pressed are placed. The calender is also a kind of press, serving to press or calender linens, silks, &c.

Presses used for expressing of liquors are of various kinds; some, in most respects, the same with the common presses, excepting that the under plank is perforated with a great number of holes, to let the juice expressed run through into a tub or receiver underneath.

Plate 142, fig. 3, is a simple packing press, described by M. Buschenderf, in *Les Annales des Arts*. **ABD** is a strong frame of wood; through the upper bar **D** a strong iron rack **E**, similar to a saw, slides a small click **e**, pushed by a spring, prevents it rising after the lever **F** has pressed it down: the lower end of this rack has the bed of the press **K** fixed to it, under which the goods **G** to be pressed are put. The lever **F** has a mortise through it, to admit the rack **E**; and a click **f**, which takes into its teeth the lever, moves round a bolt **g**, as a centre, which can be put through any of the holes in the beam, according to the quantity of the goods to be pressed. The machine operates as follows: When the lever **F** is lifted up its click **f** slips over the sloping side of the teeth, and when it is pulled down the click takes hold of the teeth and draws the rack down with it another tooth: the click **e** then holds it, while the lever is raised to take another tooth as before. The only objection to this simple press is a want of power for pressing many articles, and that the teeth of the rack could not be made fine enough for a man to press down a whole tooth without resting. To remedy the first inconvenience, it has occurred to us that a bolt **h** might be put through two of the beams, and the end of a common handspike **H** put under it. This handspike might be connected with **F** by an endless chain put over both: this chain might have a hook at the end, so as to shorten or lengthen it by hooking it into another link, as occasion required. For the second inconvenience a plate of iron **i**, with teeth in it, might be fastened to the lever **F**, and a long click **I**, connected with the frame, might fall into them, so as to prevent the lever rising. By this means each tooth of the rack may be divided into four or five parts; and when the click **e** takes hold of a new tooth, the long click **I** may be lifted up, and the lever raised. As before, the click might be hooked up when the press **I** is used as above described: the chain or

handspike may be taken away and replaced in a very short time.

Fig. 4. is a screw-press, used for expressing some kinds of oil; the frame ADB is formed of one piece of cast-iron, the upper piece has a brass nut fixed in it, through which the screw E works; the screw has holes through its lower end, to put in a long iron lever F, by which the screw is turned. The substance from which the oil is to be pressed, is tied up in horse-hair bags, and laid under the bed of the press G, with a warm iron plate between each bag; the screw is then turned by men, as long as they can move it; a rope is then hooked to the end of the lever, and the power of a windlass or capstan is used to assist the lever: the oil weeps out of the bags, and runs down through a spout into the reservoir H, placed to raise it.

Fig. 5. is a representation of the hydrostatic press for which Mr. Bramah took out a patent in 1796. The frame of this is like a common press; the bed A is fastened to the piston B, of a stout brass barrel D, the lower end of which communicates by a pipe E, with a forcing pump within the cylindric vessel F; the piston *ff* of this is cut hollow, and has the connecting rod *g* jointed within side of it. The lever *b*, which works the pump, is jointed to the lower end of this rod, so that the circular motion of the lever is allowed by the connecting rod *g* moving in or out of the hollow in the piston rod; and the parallelism of the piston is preserved by a collar H.

Fig. 6. and 7. explain the construction of the pump within the cistern F; I is the barrel of brass, this has the piece J screwed into it lower, and this piece J is screwed into the end of the pipe E, and contains within it a valve opening downwards. To the part L of the barrel, the piece K containing a valve opening inwards is screwed; this is open to the water, oil, &c. contained in the cistern F, when the lever G is raised, the barrel fills with water through the valve K, and when it is pushed down, the valve K shuts, J opens, and the water is forced through the pipes E into the large barrel D, and by pushing out its piston B, presses the goods laid upon the bed A of the press. When the goods are sufficiently pressed, the lever G is pushed down, and the lower end of the piston opens the valves JK, and the detent *k* pushes towards the piston, opens the valves K, which allows the water to pass back into the reservoir, the bed of the press falls down, the valves are composed of a small brass cone, (fig. 4.) which exactly fits its seat, and is kept in its place by a wire fastened to it; this wire is cut flat on one side to allow the water to pass through when the valve is open, and a small spiral spring closes it. (*Gregory's Cyclo.*)

PRESS used by joiners, to keep close the pieces they have glued, especially pannels, &c. of wainscot is very simple, consisting of four members, viz. two screws, and two pieces of wood, four or five inches square, and two or three feet long; whereof the holes at the two ends serve for nuts to the screws.

PRESS (Liberty of the). See LIBERTY.

PRESSBED. *s.* (*press and bed.*) Bed so formed as to be shut up in a case.

PRESSER. *s.* (*from press.*) One that presses or works at press (*Swift*).

PRESSGANG. *s.* (*press and gang.*) A crew that strolls about the streets to force men into naval service.

PRESSING, in the manufactures, is the violently squeezing a cloth, stuff, &c. to render it smooth and glossy. There are two methods of pressing, viz. cold or hot. As to the former, or cold-pressing, after the stuff has been scoured, fulled, and shorn, it is folded square in equal plaits, and a skin of vellum, or pasteboard, put between each plait. Over the whole is laid a square wooden plank, and so put into the press, which is screwed down tight by means of a lever. After it has lain a sufficient time in the press, they take it out, removing the pasteboards, and lay it up to keep. Some only lay the stuff on a firm table, after plaiting and pasteboarding cover the whole with a wooden plank, and load it with a proper weight.

The method of pressing hot is this: when the stuff has received the above preparations, it is sprinkled a little with water, sometimes gum-water, then plaited equal, and between each two plaits are put leaves of pasteboard; and between every sixth or seventh plait, as well as over the whole, an iron or brass plate well heated in a kind of furnace. This done it is laid upon the press, and forcibly screwed down. Under this press are laid five, six, or more pieces, at the same time, all furnished with their pasteboards and iron-plates. When the plates are well cooled, the stuffs are taken out and stitched a little together to keep them in the plaits. This manner of pressing, however, was only invented to cover the defects of stuffs; and accordingly it has been frequently prohibited.

PRESSINGLY. *ad.* (*from pressing.*) With force; closely (*Howell*).

PRESSION. *s.* (*from press.*) The act of pressing (*Newton*).

PRESSITANT. *a.* Gravitating; heavy (*More*).

PRESSMAN. *s.* (*press and man.*) 1. One who forces another into service; one who forces away (*Chapman*). 2. One who makes the impression of print by the press: distinct from the compositor, who ranges the types.

PRESSMONEY. *s.* (*press and money.*) Money given to a soldier when he is taken or forced into the service (*Gay*).

PRESSURE. *s.* (*from press.*) 1. The act of pressing or crushing. 2. The state of being pressed or crushed. 3. Force acting against any thing; gravitation; weight acting or resisting (*Newton*). 4. Violence inflicted; oppression (*Bacon*). 5. Affliction; grievance; distress (*Atterbury*). 6. Impression; stamp; character made by impression (*Shakspeare*).

PRESSURE, is properly the action of a body which makes a continual effort or endeavour to move another; such as the action of a heavy body supported by a horizontal table; in contradistinction from percussion, or a momentary

force or action. Pressure equally respects both bodies, that which presses, and that which is pressed; from the mutual equality of action and reaction.

For remarks on the difference between pressure and percussion, see our articles IMPULSION and PERCUSSION.

PRESSURE OF FLUIDS. See HYDROSTATICS and PNEUMATICS.

PRESSURE (Centre of). See PRESSURE.

PREST. *a.* (*prest*, or *prêt*, Fr.) Obsolete.
1. Ready; not dilatory (*Fairfax*). 2. Neat; tight (*Tusser*).

PREST. *s.* (*prest*, Fr.) A loan (*Bacon*).

PRESTATION-MONEY, is a sum of money paid yearly by archdeacons and other dignitaries to their bishop, *pro exteriori jurisdictione*.

PRESTATION (*prestatio*), was anciently used for other payments: *Et quieti sint de prestatione muragii*. Chart. Hen. VII. Sometimes also for pourveyance.

PRESTEIGN is a town of Radnorshire, distant 149 miles W.N.W. from London, in the direct road to Aberystwith, and throughout South Wales, in N. lat. 52° 12', bounded to the north and north-east by Herefordshire. It is a neat well-built town, with clean and regular streets, and is the residence of many genteel families. The neighbourhood abounds with all the comforts and conveniences of life. It is seated on a gravelly soil on the banks of the river Lug, and at the head of a very fertile vale; the mountains to the west and north-west of the town forming, as it were, an amphitheatre round it. The name of it in Welsh is *Slan-Andras*, which is supposed to be derived from the church, which is dedicated to Saint Andrew. The town is divided into four wards, which have each a separate jurisdiction, separate officers, levies, &c. The curfew-bell of William the Conqueror still remains in this place, and is rung every night. It is a borough by prescription, and is governed by a bailiff annually elected, and sworn in by a steward appointed by the crown.

PRESTER (JOHN or JEAN), an appellation formerly given to an emperor of the Tartars, who was overcome and killed by Jenghiz Khan. Since that time it has been given to the emperor of Abyssinia or Ethiopia: however, in Ethiopia itself this name is utterly unknown, the emperor being there called the grand negus.

PRESTER, a meteor, consisting of an exhalation thrown from the clouds downwards with such violence, as that by the collision it is set on fire. The word is Greek, *πρεστηρ*, the name of a kind of serpent; called also *dipsas*, to which this meteor is supposed to bear a resemblance. The prester differs from the thunderbolt in the manner of its inflammation; and in its burning and breaking every thing it touches with greater violence. The exhalation, however, is usually supposed to be electric; and the meteor to be of the nature of the water-spout. See LUCRETIVS, vi. 23, and Good's note upon the passage.

PRESTER, a word used by some to express

the external part of the neck, which is usually inflated in anger.

PRESTIGATION. *s.* (*præstigatio*, Latin.) A deceiving; a juggling; a playing legerdemain.

PRESTIGES. *s.* (*præstigia*, Lat.) Illusions; impostures; juggling tricks.

PRETISSIMO. (Ital.) In music, the superlative of *presto*. A word denoting the most rapid time.

PRESTO. (Ital.) A word implying that the movement at the beginning of which it is placed is to be performed in a very quick, though not the quickest, time.

PRESTON, a town of England, in the county of Lancaster. This is a large and handsome town, situated on the Ribble, which is navigable for small vessels. Near this town the Scotch were routed, under the command of the duke of Hamilton, who came to assist Charles I.; and in the year 1715, the rebels were defeated by the troops of George I. Here are three markets weekly, Wednesday, Friday, and Saturday. Every twentieth year, a guild or jubilee is held here, which begins the latter end of August, and continues a month. Preston sends two members to the British parliament: 21 miles S. Lancaster, and 214 N.N.W. London. Lon. 2. 53 W. Lat. 53. 46 N.

PRESTON PANS, a village in Haddingtonshire, noted for its saltworks, and for the defeat of the royal army by the rebels, in 1745. It is four miles W. of Haddington.

PRESUMABLY. *ad.* (from *presume*.) Without examination (*Brown*).

To PRESUME. *v. n.* (*presumer*, French; *presumo*, Latin.) 1. To suppose; to believe previously without examination (*Milton*). 2. To suppose; to affirm without immediate proof (*Brown*). 3. To venture without positive leave (*Milton*). 4. To form confident or arrogant opinions (*Locke*). 5. To make confident or arrogant attempts (*Hooker*).

PRESUMER. *s.* (from *presume*.) One that presupposes; an arrogant person (*Wotton*).

PRESUMPTION. *s.* (*præsumptus*, Lat. *presumption*, Fr.) 1. Supposition previously formed (*K. Charles*). 2. Confidence grounded on any thing presupposed (*Clarendon*). 3. An argument strong, but not demonstrative; a strong probability (*Hooker*). 4. Arrogance; confidence blind and adventurous; presumptuousness (*Dryden*). 5. Unreasonable confidence of divine favour (*Rogers*).

PRESUMPTIVE. *a.* (*presumptif*, French.) 1. Taken by previous supposition (*Locke*). 2. Supposed: as, the presumptive heir: opposed to the heir apparent. 3. Confident; arrogant; presumptuous (*Brown*).

PRESUMPTUOUS. *a.* (*presumptueux*, French.) 1. Arrogant; confident; insolent (*Shakspeare*). 2. Irreverent with respect to holy things (*Milton*).

PRESUMPTUOUSLY. *ad.* 1. Arrogantly; confidently. 2. Irreverently (*Addison*). 3. With vain and groundless confidence in divine favour (*Hammond*).

PRESUMPTUOUSNESS. *s.* (from *pre-*

sumptuous.) Quality of being presumptuous; confidence; irreverence.

PRESUPPOSAL. *s.* (*pre* and *supposal.*) Supposal previously formed (*Hooker*).

To PRESUPPOSE. *v. a.* (*presupposer*, French; *pre* and *suppose.*) To suppose as previous; to imply as antecedent (*Hooker*).

PRESUPPOSITION. *s.* (*presupposition*, Fr.) Supposition previously formed.

PRESURMISE. *s.* (*pre* and *surmise.*) Surmise previously formed (*Shakspeare*).

PRETENCE. *s.* (*prætensus*, Latin.) 1. A false argument grounded upon fictitious postulates (*Tillotson*). 2. The act of showing or alleging what is not real; show; appearance (*Wake*). 3. Assumption; claim to notice (*Evelyn*). 4. Claim true or false (*Milton*). 5. Something threatened, or held out to terrify (*Shakspeare*).

To PRETEND. *v. a.* (*prætendo*, Latin.) 1. To hold out; to stretch forward (*Dryden*). 2. To simulate; to make false appearances or representations; to allege falsely (*Milton*). 3. To show hypocritically (*Decay of Piety*). 4. To hold out a delusive appearance (*Milton*). 5. To claim (*Dryden*).

To PRETEND. *v. n.* 1. To put in a claim truly or falsely (*Dryden*). 2. To presume on ability to do any thing; to profess presumptuously (*Brown*).

PRETENDER. *s.* (from *pretend.*) One who lays claim to any thing (*Pope*).

PRETENDINGLY. *ad.* (from *pretending.*) Arrogantly; presumptuously (*Collier*).

PRETENSION. *s.* (*prætensio*, Latin.) 1. Claim true or false (*Swift*). 2. Fictitious appearance (*Bacon*).

PRETER. *s.* (*præter*, Latin.) A particle which, prefixed to words of Latin original, signifies *beside*.

PRETERIMPERFECT. *a.* In grammar, denotes the tense not perfectly past.

PRETERITE. *a.* (*preterite*, French; *præteritus*, Latin.) Past. See **GRAMMAR**.

PRETERITION. *s.* (*preterition*, French; from *preterite.*) The act of going past; the state of being past.

PRETERITION, or PRETERMISSION, in rhetoric, a figure whereby, in pretending to pass over a thing untouched, we make a summary mention thereof. "I will not say he is valiant, he is learned, he is just," &c. The most artful praises are those given by way of preterition.

PRETERITNESS. *s.* (from *preterit.*) State of being past; not presence; not futurity.

PRETERLAPSED. *a.* (*præterlapsus*, Lat.) Past and gone (*Walker*).

PRETERLEGAL. *a.* (*preter* and *legal.*) Not agreeable to law (*King Charles*).

PRETERMISSION. *s.* (*pretermission*, Fr.) The act of omitting.

To PRETERMIT. *v. a.* (*prætermitto*, Lat.) To pass by (*Bacon*).

PRETERNATURAL. *a.* (*preter* and *natural.*) Different from what is natural; irregular.

PRETERNATURALLY. *ad.* In a manner different from the order of nature (*Bacon*).

PRETERNATURALNESS. *s.* (from *preternatural.*) Manner different from the order of nature.

PRETERPERFECT. *a.* (*præteritum perfectum*, Latin.) A grammatical term applied to the tense which denotes time absolutely past (*Addison*).

PRETERPLUPERFECT. *a.* (*præteritum plusquam perfectum*, Latin.) The grammatical epithet for the tense denoting time relatively past, or past before some other past time.

PRETEXT. *s.* (*pretextus*, Lat.) Pretence; false appearance; false allegation (*Daniel*).

PRETEXTA (Toga), among the ancient Romans, a long white gown, with a border of purple round the edges, and worn by children of quality till the age of puberty, viz. by the boys till 17, when they changed it for the toga virilis; and by the girls till marriage.

PRETIUM SEPULCHRI, in old law books, &c. those goods accruing to the church wherein a corpse is buried. In the Irish canons, lib. xix. cap. 6. it is ordered, that along with every body that is buried, there go his cow, horse, apparel, and the furniture of his bed; none of which may be disposed of otherwise than for the payment of debts, &c. as being familiars and domestics of the deceased.

PRETOR, a magistrate among the ancient Romans, not unlike our lord chief justices, or lord chancellor, or both in one; as being vested with the power of distributing justice among the citizens. At first there was only one pretor; but afterwards, another being created, the first or chief one had the title of *prætor urbanus*, or the city pretor: the other was called *peregrinus*, as being judge in all matters relating to foreigners. But, besides these, there were afterwards created many provincial pretors; who were not only judges, but also assisted the consuls in the government of the provinces, and even were invested with the government of provinces themselves.

PRETORIAN GUARD, in Roman antiquity, were the emperor's guards, who at length were increased to 10,000 men: they had this denomination, according to some, from their being stationed at a place called *Prætorium*; their commander was styled *præfectus prætorii*.

PRETORIUM, or PRÆTORIUM, among the Romans, denoted the hall or court wherein the pretor lived, and wherein he administered justice. It likewise denoted the tent of the Roman general, wherein councils of war, &c. were held: also a place in Rome where the Pretorian guards were lodged.

PRETTILY. *ad.* (from *pretty.*) Neatly; elegantly; pleasingly without dignity or elevation (*Bacon*).

PRETTINESS. *s.* (from *pretty.*) Beauty without dignity; neat elegance without elevation (*More*).

PRETTY. *a.* (*pnæz*, finery, Saxon; *pretto*, Italian; *prat*, *prattigh*, Dutch; *pretium*, Lat.) 1. Neat; elegant; pleasing without surprise or elevation (*Watts*). 2. Beautiful without grandeur or dignity (*Spectator*). 3. It is used

in a kind of diminutive contempt in poetry, and in conversation: as, *a pretty fellow indeed!* (Addison). 4. Not very small. A vulgar use (Abbot).

PRE'TTY. *ad.* In some degree: it is less than very; *the words are pretty good*; that is, not very good (Addison. Baker).

To PREVAIL. *v. n.* (*prevailoir*, French.) 1. To be in force; to have effect; to have power; to have influence (Locke). 2. To overcome; to gain the superiority (Shakspeare). 3. To gain influence; to operate effectually (Wilkins). 4. To persuade or induce (Clarendon).

PREVAILING. *a.* (from *prevail*.) Predominant; having much influence (Rowe).

PREVAILMENT. *s.* (from *prevail*.) Prevalence (Shakspeare).

PREVALENCE. **PRE'VALENCY.** *s.* (*prevalence*, Fr. *prævalentia*, low Latin.) Superiority; influence; predominance; efficacy; force; validity (Clarendon).

PREVALENT. *a.* (*prævalens*, Latin.) 1. Victorious; gaining superiority (South). 2. Powerful; efficacious (Milton). 3. Predominant (Woodward).

PREVALENTLY. *ad.* (from *prevalent*.) Powerfully; forcibly (Prior).

To PREVARIATE. *v. n.* (*prævaricor*, Lat.) To cavil; to quibble; to shuffle (Stillingfleet).

PREVARICATION. *s.* (*prævaricatio*, Lat.) Shuffle; cavil (Addison).

PREVARICATOR. *s.* (*prævaricator*, Lat.) A caviller; a shuffler.

To PREVENIE. *v. a.* (*prævenio*, Lat.) To hinder (Philips).

PREVENIENT. *a.* (*præveniens*, Lat.) Preceding; going before; preventive (Milton).

To PREVENT. *v. a.* (*prævenio*, Lat. *prevenir*, Fr.) 1. To go before as a guide; to go before, making the way easy (Common Prayer). 2. To go before; to be before (Bacon). 3. To anticipate (Pope). 4. To preoccupy; to preengage; to attempt first (King Charles). 5. To hinder; to obviate; to obstruct (Atterbury).

To PREVE'NT. *v. a.* To come before the time. A latinism (Bacon).

PREVENTATIVE. See **PREVENTIVE** and **PROPHYLACTIC**.

PREVENTER. *s.* (from *prevent*.) 1. One that goes before (Bacon). 2. One that hinders; a hinderer; an obstructor.

PREVENTION. *s.* (*prevention*, French; from *præventum*, Latin.) 1. The act of going before (Milton). 2. Preoccupation; anticipation (Shakspeare). 3. Hinderance; obstruction (Milton). 4. Prejudice; prepossession (Dryden).

PREVENTIONAL. *a.* (from *prevention*.) Tending to prevention.

PREVENTIVE. *a.* (from *prevent*.) 1. Tending to hinder (Bacon). 2. Preservative; hindering ill (Brown).

PREVENTIVE. *s.* (from *prevent*.) A preservative; that which prevents; an antidote.

PREVENTIVELY. *ad.* In such a manner as tends to prevention (Brown).

PREVESA, a seaport of Turkey in Europe, in Albania, with a bishop's see. It stands on the ruins of the ancient Nicopolis, built by emperor Augustus, in memory of his victory over Antony. It belongs to the Venetians, and was taken by them in 1684. It is seated on a mountain, on the gulph of Larta, 70 miles N.W. of Lepanto. Lon. 21. 5 E. Lat. 39½ 14 N.

PREUILLY, a town of France, in the department of Indre and Loire. Near it are mines of iron; and to the S.W. is La Haye, a small town on the Creuse, famous as the birthplace of Descartes. Preuilly is seated on the Claise, 18 miles S. of Loches.

PREVIOUS. *a.* (*prævius*, Latin.) Antecedent; going before; prior (Burnet).

PREVIOUSLY. *ad.* Beforehand; antecedently (Prior).

PREVIOUSNESS. *s.* (from *previous*.) Antecedence.

PREY. *s.* (*præda*, Latin.) 1. Something to be devoured; something to be seized; ravin; plunder (Clarendon). 2. Ravage; depredation (Shakspeare). 3. Animal of prey, is an animal that lives on other animals (L'Estrange).

To PREY. *v. n.* (*prædor*, Latin.) 1. To feed by violence (Shakspeare). 2. To plunder; to rob (Shakspeare). 3. To corrode; to waste (Addison).

PREYER. *s.* (from *prey*.) Robber; devourer; plunderer.

PRIAMIDES, a patronymic applied to Paris and all the other children of Priam.

PRIAMUS, **PRIAM**, the last king of Troy, was son of Laomedon. When Hercules took the city of Troy, (see **LAOMEDON**) Priam was in the number of his prisoners, but his sister Hesione redeemed him from captivity, and he exchanged his original name, which was Podarces, for that of Priam, which signifies bought or ransomed. Being placed on his father's throne by Hercules, he employed himself with uncommon diligence in fortifying and embellishing the city of Troy. He now divorced Arisba for Hecuba, the daughter of Cisseus. He had by Hecuba 17 children, according to Homer, 19; the most celebrated of whom are Hector, Paris, Deiphobus, Helenus, Pammon, Polites, Antiphus, Hipponous, Troilus, Creusa, Laodice, Polyxena, and Cassandra. Besides these he had many others by concubines. After he had reigned for some time, Priam expressed a desire to recover his sister Hesione, whom Hercules had carried into Greece, and married to Telamon his friend. He manned a fleet of which he gave the command to his son Paris, with orders to bring back Hesione. Paris neglected his father's injunctions, and carried away Helen, the wife of Menelaus, king of Sparta, during the absence of her husband. Priam countenanced his son, by receiving in his palace the wife of the king of Sparta. This rape kindled the flames of the Trojan war. Troy, after a ten years' siege, having been betrayed

into the hands of the Greeks, and Hector, the chief support of the Trojans, slain by Achilles, Priam resolved to die in defence of his country. He put on his armour, and advanced to meet the Greeks, but was detained by the tears and entreaties of his wife at the altar of Jupiter, to which Polites, one of his sons, fled, in the mean time, from the fury of Neoptolemus, who pursued him. The son, wounded and overcome, fell dead at the feet of his parents. The aged father raised his spear, which he darted at Neoptolemus; it only touched his buckler, and fell to the ground. Neoptolemus seized the grey hair of Priam, and plunged his dagger into his breast. His head was cut off, and the mutilated body was left among the heaps of slain.

PRIAPEIA. See **NICOTIANA MINOR**.

PRIAPISM. (*priapismus*, *πριαπισμος*, from *πριαπος*, a heathen god, whose penis is always painted erect.) A continual erection of the penis.

PRIAPUS, a deity among the ancients, who presided over gardens, and the parts of generation in the sexes. He was son of Venus by Bacchus. Priapus was so deformed, that his mother, ashamed to give birth to such a monster, ordered him to be exposed on the mountains. His life, however, was preserved by

shepherds, and he received the name of Priapus, *propter deformitatem & membri virilis magnitudinem*. Festivals were also celebrated in honour of him by the people of Lampsacus, and they gave themselves up to every lasciviousness and impurity during the celebration. His worship was also introduced in Rome; but the Romans revered him more as a god of orchards and gardens, than as the patron of licentiousness. He is generally represented with an human face, and the ears of a goat; he holds a stick in his hand, with which he terrifies birds, as also a club to drive away thieves, and a scythe to prune the trees and cut down the corn.—2. A town of Asia Minor, near Lampsacus. Priapus was the deity of the place, and from him the town received its name, because he had taken refuge there when banished from Lampsacus.

PRIBODA, a town of Sweden, in the province of Smaland, 16 miles S.S.W. of Carlscrona. Lon. 15. 18 E. Lat. 56. 10 N.

PRICE. *s.* (*prix*, Fr. *pretium*, Lat.) 1. Equivalent paid for any thing (*Bacon*). 2. Value; estimation; supposed excellence (*Bacon*). 3. Rate at which any thing is sold (*Locke*). 4. Reward; thing purchased by merit (*Pope*).

To PRICE. v. a. To pay for (*Spenser*),

A TABLE exhibiting the PRICES of various NECESSARIES of LIFE, together with that of Day Labour, in Sterling Money, and also in Decimals, at different Periods from the Conquest to the Year 1800, derived from respectable Authorities; with the Depreciation of the Value of Money inferred therefrom. To which is added, the mean Appraisal of Money, according to a Series of Intervals of 50 Years; and, during the present Century, at shorter Periods, deduced by Interpolation. By Sir George Shuckburgh Evelyn, Bart. F. R. S. and A. S. (From the Philosophical Transactions.)

* The smaller figures denote the price in decimals, whereof those for the year 1550 may be taken for the integer, viz. 100.

PRICE (Rev. Richard), D.D. LL.D. fellow of the royal society of London, and of the academy of sciences, New England, was born at Tynton in Glamorganshire, February 22, 1723. His father was a dissenting minister at Bridgend in that county, and died in 1739. At eight years old he was placed under a Mr. Simmons of Neath; and in four years removed to Pentwyn in Caermarthenshire under the Rev. Samuel Jones, whom he represented as a man of a very enlarged mind, and who first inspired him with liberal sentiments of religion. Having lived as long with him as with Mr. Simmons, he was sent to Mr. Griffith's academy at Talgarth in Breconshire. In 1740 he lost his mother; and on this he quitted the academy and came to London. Here he was settled at that academy of which Mr. Eames was the principal tutor, under the patronage of his uncle the Rev. S. Price, who was co-pastor with Dr. Watts upwards of 40 years. At the end of four years he left this academy, and resided with Mr. Streatfield of Stoke Newington in the quality of domestic chaplain, while at the same time he regularly assisted Dr. Chandler at the Old Jewry, and occasionally assisted others. Having lived with Mr. Streatfield near 13 years, on his death and his uncle's he was induced to change his situation, and in 1757 married Miss S. Blundell of Leicestershire. He then settled at Hackney; but being shortly after chosen minister at Newington Green, he lived there until the death of his wife, which was in 1786, when he returned to Hackney. He was next chosen afternoon-preacher at the meeting-house in Poor Jewry-street; but this he resigned on being elected pastor of the Gravel-pit meeting, Hackney, and afternoon-preacher at Newington Green. These he resigned with a farewell-sermon in February 1791. Shortly after he was attacked with a nervous fever; which disappearing was succeeded by a disorder in his bladder, which reduced him to such a degree that, worn out with agony and disease, he died without a groan on the 19th of April, 1791. He left his property to a sister and two nephews.

Dr. Kippis, speaking of his learning and pursuits, observes, that "his chief aim was to lay a foundation for solid knowledge, by an application to sciences of the noblest kind. It was on the great and fundamental principles and obligations of morality, on the higher species of mathematics, on the sublimer parts of natural philosophy, on the true basis of government, and on the questions which relate to the essential welfare and dignity of man, that his studies were employed; and in the prosecution of these studies he not only enriched his own mind, but was enabled to become of eminent service to his country and to the world. In his moral writings he has laboured with distinguished ability to build the science of ethics on an immutable basis; and what he has advanced will always stand high in estimation, as one of the strongest efforts of human reason in favour of the system he has adopted. For myself (adds Dr. Kippis), I

scruple not to say, that I regard the treatise referred to as a rich treasure of valuable information, and as deserving to be ranked among the first productions of its kind. With respect to his other ethical works, every one must admire the zeal, earnestness, and strength, with which he endeavours to lead men into pious views of God, of providence and prayer; and to promote the exercise of devout and amiable dispositions. In consequence of his profound knowledge in mathematical calculations, he was qualified at a particular crisis for being of singular utility to his fellow-citizens. A number of schemes for insurance for lives, and the benefit of survivorship, promising mighty advantages, were rising up in the metropolis. These ruinous schemes would have been carried to great excess, had not Dr. Price stepped forward and dispelled the delusion. Gratitude will not allow us to forget the ability and spirit with which he awakened the attention of his countrymen to the reduction of the national debt. With him it was that the scheme of the late Mr. Pitt for that purpose originated. What crowned the whole of his character was, its being an assemblage of the most amiable and excellent private virtues. His piety was sincere, humble, and fervent; his soul pure and elevated. In his views disinterested and noble, and in his manners mild and gentle, the applause of his talents and virtues will be transmitted to future ages, and he will be united in the catalogue with the most eminent benefactors of mankind."

This is the panegyric of a friend; but with few abatements it will be admitted, we apprehend, by most of our readers.

The works of Dr. Price were, *A Review of the principal Questions and Difficulties in Morals*, 8vo. 1758; *Dissertations on Providence*, &c. 8vo. 1767; *Observations on Reversionary Payments*, &c. 8vo. 1771; *Appeal on the National Debt*, &c. 8vo. 1773; *Observations on the Nature of Civil Liberty*, 1776; on *Materialism and Necessity*, in a *Correspondence between Dr. Price and Dr. Priestley*, 1779; on *Annuities, Assurances, Population*, &c. 8vo. 1779; on the *Population of England*, 1780; on the *Public Debts, Finances, Loans*, &c. 8vo. 1783; on *Reversionary Payments*, 2 vols. 1783; on the *Importance of the American Revolution*, 1784: besides *Sermons*, and a variety of papers in the *Philosophical Transactions* on astronomical and other philosophical subjects.

To PRICK. *v. a.* (priecken, Saxon.) 1. To pierce with a small puncture (*Arbutnot*). 2. To form or erect with an acuminate point (*Bacon*). 3. To fix by the point (*Newton*). 4. To hang on a point (*Sundys*). 5. To nominate by a puncture or mark (*Shakspeare*). 6. To spur; to goad; to impel; to incite (*Sh.*). 7. To pain; to pierce with remorse (*Acts*). 8. To make acid (*Hudibras*). 9. To mark a tune.

To PRICK. *v. n.* (*prijken*, Dutch.) 1. To dress one's self for show. 2. To come upon the spur (*Spenser*).

PRICK. *s.* (*pricca*, Saxon.) 1. A sharp slender instrument; any thing by which a puncture is made (*Davies*). 2. A thorn in the mind; a teasing and tormenting thought; remorse of conscience (*Shakspeare*). 3. A spot or mark at which archers aim (*Carew*). 4. A point; a fixed place (*Shakspeare*). 5. A puncture (*Brown*). 6. The print of a hare in the ground.

PRICKER. *s.* (from *prick*.) 1. A sharp-pointed instrument (*Moxon*). 2. A light horseman; not used (*Hayward*).

PRICKET. *s.* (from *prick*.) A buck in his second year (*Manwood*).

PRICKING, in farriery, a very common accident which happens to the horse in shoeing. (See **PUNCTURE**.) It takes place either in consequence of the farrier's rashness in entering the nail too close to the sensible parts, or of the accidental bending of the nail in an unfavourable direction afterwards. When this happens the horse soon becomes lame; and it will be necessary, in the first instance, to draw the nail which has occasioned the mischief, and, secondly, to apply such remedies as are likely to abate inflammation in the foot. Instead of this, however, it is too common to treat the part with stimulating oils and tinctures.

PRICKLE. *Aculeus.* In botany, a sharp process from a plant, fixed into the bark only: as in rose, bramble, gooseberry, and barberry. This and the thorn are called *arma* by Linneus, and are enumerated among the fulcres.

Prickles are straight—bent in, incurvate; or bent back, recurvate.—When divided, they take the name of *furcæ*, forks or forked prickles; and are called *bifid*, *trifid*, &c. from the number of divisions.

PRICKLINESS. *s.* (from *prickly*.) Fulness of sharp points.

PRICKLOUSE. *s.* (*prick* and *louse*.) A word of contempt for a tailor (*L'Estrange*).

PRICKLY. *a.* (from *prick*.) Full of sharp points (*Bacon*).

PRICKLY PEAR, in botany. See **CACTUS**.

PRICKPUNCH. *s.* A piece of tempered steel, with a round point at one end, to prick a round mark in cold iron (*Moxon*).

PRICKSONG. *s.* (*prick* and *song*.) Song set to music (*Shakspeare*).

PRICKWOOD, in botany. See **EVENY-MUS**.

PRIDE. *s.* (*priz*, or *prýð*, Saxon.) 1. Inordinate and unreasonable self-esteem (*Milt.*). 2. Insolence; rude treatment of others; insolent exultation (*Milton*). 3. Dignity of manner; loftiness of air. 4. Generous elation of heart (*Smith*). 5. Elevation; dignity (*Sha.*). 6. Ornament; show; decoration (*Milton*). 7. Splendour; ostentation (*Dryden*). 8. The state of a female beast soliciting the male (*Shakspeare*).

Pride may be distinguished from words nearly synonymous, in the following manner.

Pride is, as above, unreasonable or inordinate

self-esteem. Arrogance implies taking much upon ourselves, and is pride attended with insolence and contempt. Vanity is accompanied with affectation, and exerts itself in catching the applause of others. By presumption is understood a blind and adventurous confidence. The proud consider themselves in their own mind; full, and self-swollen, they are taken up with their own person. The arrogant claim to themselves what they have not the least pretensions to; are ready to insult those who will not allow them what they claim, and look down on the rest of the world with contempt. The vain value themselves upon the opinion of others; greedy of esteem, they are eager to engross the attention of all mankind. The presumptuous carry their audacious hopes even to chimeras; bold to undertake, they fondly imagine they have power to do every thing.

For some very excellent remarks on the dangerous moral tendency of pride, we refer to a valuable sermon on Modern Infidelity by Robert Hall, A. M.

PRIDE, in ichthyology. See **PETROMYZON**.

To PRIDE. *v. a.* (from the noun.) To make proud; to rate himself high.

PRIDEAUX (*Humphrey*), was born at Padstow in Cornwall in 1648. He studied three years at Westminster under Dr. Busby; and was thence removed to Christ-church, Oxford. Here he published, in 1676, his *Marmora Oxoniensia ex Arundelianis, Seldenianis, alisque conflata, cum perpetuo Commentario*. This introduced him to the lord chancellor Finch, afterwards earl of Nottingham, who in 1679 presented him to the rectory of St. Clement near Oxford, and in 1681 bestowed on him a prebend of Norwich. Some years after he was engaged in a controversy with the papists at Norwich, concerning the validity of the orders of the church of England, which produced his book upon that subject. In 1688 he was installed in the archdeaconry of Suffolk; to which he was collated by Dr. Lloyd, then bishop of Norwich. In 1691, upon the death of Dr. Edward Pococke, the Hebrew professorship at Oxford, being vacant, was offered to Dr. Prideaux; but he refused it. In 1697 he published his *Life of Mahomet*, and in 1702 was installed dean of Norwich. In 1710 he was cut for the stone; which interrupted his studies for more than a year. Some time after his return to London, he proceeded with his *Connection of the History of the Old and New Testament*; which he had begun when he laid aside the design of writing the *History of Appropriations*. He died in 1724.

PRIEBUS, a town of Silesia, in the principality of Sagan, situate on the Neisse, 15 miles S.W. of Sagan. Lon. 15. 12 E. Lat. 51. 32 N.

PRIENE, a maritime town of Asia Minor, one of the twelve independent cities of Ionia. It gave birth to Bias, one of the seven wise men of Greece (*Paus.*).

PRIEF, for *proof* (*Spenser*).

PRI

PRIER. *s.* (from *pry.*) One who inquires too narrowly.

PRIEST. *s.* (*ppretz*, Saxon; *prestre*, Fr.)

1. One who officiates in sacred offices (*Milton*).
2. One of the second order in the hierarchy, above a deacon, below a bishop (*Rowe*).

PRIEST, a person set apart for the performance of sacrifice, and other offices and ceremonies of religion. Before the promulgation of the law of Moses, the first-born of every family, the fathers, the princes, and the kings were priests. Thus Cain and Abel, Noah, Abraham, Melchizedec, Job, Isaac, and Jacob, offered themselves their own sacrifices. Among the Israelites, after their exodus from Egypt, the priesthood was confined to one tribe, and it consisted of three orders, the high-priest; priests, and levites. The priesthood was made hereditary in the family of Aaron, and the first-born of the oldest branch of that family, if he had no legal blemish, was always the high-priest. This divine appointment was observed with considerable accuracy till the Jews fell under the dominion of the Romans, and had their faith corrupted by a false philosophy. Then, indeed, the high-priesthood was sometimes set up to sale; and instead of continuing for life, as it ought to have done, it seems, from some passages in the New Testament, to have been nothing more than an annual office. There is sufficient reason, however, to believe, that it was never disposed of but to some descendant of Aaron, capable of filling it, had the older branches been extinct.

It has been much disputed, whether in the Christian church there be any such officer as a priest, in the proper sense of the word. The church of Rome, which holds the propitiatory sacrifice of the mass, has of course her proper priesthood. In the church of England, the word priest is retained to denote the second order in her hierarchy, but, we believe, with very different significations, according to the different opinions entertained of the Lord's supper. Some few of her divines, of great learning, and of undoubted protestantism, maintain that the Lord's supper is a commemorative and eucharistical sacrifice. These consider all who are authorised to administer that sacrament as in the strictest sense priests. Others hold the Lord's supper to be a feast upon the one sacrifice, once offered on the cross; and these too must consider themselves as clothed with some kind of priesthood. Great numbers, however, of the English clergy, perhaps the majority, agree with the church of Scotland, in maintaining that the Lord's supper is a rite of no other moral import than the mere commemoration of the death of Christ. These cannot consider themselves as priests in the rigid sense of the word, but only as presbyters, of which the word priest is a contraction of the same import with elder. *

PRIESTCRAFT. *s.* (*priest and craft.*) Religious fraud; management of wicked priests to gain power (*Spectator*).

PRIESTESS. *s.* (from *priest.*) A woman who officiated in heathen rites (*Addison*).

PRI

PRIESTHOOD. *s.* (from *priest.*) 1. The office and character of a priest (*Whitgift*). 2. The order of men set apart for holy offices (*Dryden*). 3. The second order in the hierarchy.

PRIESTLEY (Joseph), an English philosopher and dissenting divine, born at Fieldhead, Yorkshire, 1733. He was educated at Daventry for the ministry among the orthodox dissenters, and took charge of a congregation at Needham market, Suffolk, and afterwards at Nantwich, Cheshire. He in process of time became a Socinian, and became in 1761, professor of belles lettres in Warrington academy, and after seven years' residence removed to Leeds, and two years after accepted the office of librarian to lord Shelburne. In this retreat the philosopher devoted himself to metaphysical and theological studies, and published various works; and when at last he separated from his patron he retired with an annual pension of £150 to settle at Birmingham as pastor to an unitarian congregation in 1780. While here employed in advancing philosophy, and often engaged in theological and political disputes, he became the victim of popular fury. Some of his neighbours in celebrating the anniversary of the French revolution in 1791, with extreme and highly censurable intemperance, excited a dreadful riot. The meeting houses were destroyed on this melancholy occasion, and among others, Dr. Priestley's house, library, manuscripts, and philosophical apparatus, were totally consumed; and though he recovered a compensation from the county, he quitted the place. He left England in 1794, and fixed his residence at Northumberland in Pennsylvania, where he died in 1804. His writings were very numerous, and on a great variety of topics, theological, political, polemical, philosophical. As a philosopher he will long class high. As a theologian he manifested much acumen and research; though with a most unphilosophical bias towards the notions he had imbibed. As a polemic, his reasonings were masterly, but often unfair and sophistical. As a man, his conduct in every relation was uniformly mild, conciliating, and exemplary.

His chief publications are, an examination of Dr. Reid's work on the human mind, Dr. Beattie's on truth, and Dr. Osborn's on common sense; disquisition on matter and spirit, in which he denied the soul's immateriality; experiments and observations on various kinds of air, 2 vols. 8vo. &c.; letters to bishop Newcome on the duration of Christ's ministry; history of the corruptions of Christianity, 2 vols. 8vo. a work of singular character, which brought on a controversy with Dr. Horsley; history of early opinions concerning the person of Christ, &c. He also published charts of history and biography; history of electricity; history and present state of discoveries relating to vision, light, and colours; lectures on the theory and history of language, and on the principles of oratory and criticism. His discoveries and improvements in the knowledge of chemistry were very great and important;

but he lived to see the general explosion of the doctrine of phlogiston, which he had so zealously established and defended.

PRIESTLINESS. *s.* (from *priestly*.) The appearance or manner of a priest.

PRIESTLY. *a.* (from *priest*.) Becoming a priest; sacerdotal; belonging to a priest.

PRIESTRIDDEN. *a.* (*priest* and *ridden*.) Managed or governed by priests (*Swift*).

To **PRIEVE**, for *prove* (*Spenser*).

PRIG. *s.* A pert, conceited, saucy, pragmatical little fellow (*Spectator*).

PRILL. *s.* A birt or turbot (*Ainsworth*).

PRIM. *a.* (by contraction from *primitive*.) Formal; precise; affectedly nice (*Swift*).

To **PRIM.** *v. a.* (from the adj.) To deck up precisely; to form to an affected nicety.

PRIMÆ VIÆ. The first passages. The stomach and the intestinal tube are so called, and the lacteals the secundæ viæ.

PRIMACY. *s.* (*primatie*, French.) The chief ecclesiastical station (*Clarendon*).

PRIMAGE. *s.* The freight of a ship.

PRIMAL. *a.* (*primus*, Latin.) First: not in use (*Shakspeare*).

PRIMARILY. *ad.* (from *primary*.) Originally; in the first intention; in the first place (*Brown*).

PRIMARINESS. *s.* (from *primary*.) The state of being first in act or intention (*Norris*).

PRIMARY. *a.* (*primarius*, Latin.) 1. First in intention (*Hammond*). 2. Original; first (*Raleigh*). 3. First in dignity; chief; principal (*Bentley*).

PRIMARY PLANETS, those which revolve about the sun as their principal centre. See **ASTRONOMY**.

PRIMARY TEETH. See **TEETH**.

PRIMATE, the chief ecclesiastic, an archbishop. With us, the archbishop of Canterbury is styled "primate of all England;" the archbishop of York, "primate of England."

PRIMATES, in zoology, the first order in the Linnéan class mammalia; thus ordinarily characterised. Fore-teeth cutting, upper four parallel (except in some species of bats, which have only two or none); tusks

solitary, or one on each side in each jaw; teats two, pectoral; feet two, which are hands; nails (usually) flattened; oval; food, fruits, except as to a few, which use animal food. The primates are remarkable for a nearer approach to the human form than is exhibited by the other quadrupeds. The bats, however, differ greatly from the rest. It consists of four genera, for which see **MASTIOLOGY** and **ZOOLOGY**.

PRIMATESHIP. *s.* (from *primate*.) The dignity or office of a primate.

PRIME. *s.* (*primus*, Latin.) 1. The first part of the day; the dawn; the morning (*Milton*). 2. The beginning; the early days (*Milton*). 3. The best part (*Swift*). 4. The spring of life, the height of strength, health, or beauty (*Dryden*). 5. Spring (*Waller*). 6. The height of perfection (*Woodward*). 7. The first canonical hour (*Ains*). 8. The first part; the beginning: as, the prime of the moon.

PRIME. *a.* (*primus*, Latin.) 1. Early; blooming (*Milton*). 2. Principal; first rate (*Clarendon*). 3. First; original (*Locke*). 4. Excellent (*Shakspeare*).

To **PRIME.** *v. a.* (from the noun.) 1. To put in the first powder; to put powder in the pan of a gun (*Boyle*). 2. (*primer*, French, to begin.) To lay the ground on a canvass to be painted.

PRIMES, in arithmetic, denote the first divisions into which some whole or integer is divided. As, a minute, or prime minute, the 60th part of a degree; or the first place of decimals, being the 10th parts of units; or the first division of inches in duodecimals, being the 12th parts of inches; &c.

PRIME NUMBERS, are those which can only be measured by unity, or exactly divided without a remainder, 1 being the only aliquot part: as 2, 3, 5, 7, 11, 13, 17, &c. And they are otherwise called simple, or incomposite numbers. No even number is a prime, because every even number is divisible by 2. No number that ends with 0 or 5 is a prime, the former being divisible by 10, and the latter by 5. The following table contains all the prime numbers under 1000.

A TABLE of Prime Numbers under 1000.

1, 2, 3, 5, 7, 11, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53,	
59, 61, 67, 71, 73, 79, 83, 89, 97	26
101, 103, 107, 113, 127, 131, 137, 139, 149, 151, 157,	
163, 167, 173, 179, 181, 191, 193, 197, 199	47
211, 223, 227, 229, 233, 239, 241, 251, 257, 263, 269,	
271, 277, 281, 283, 293	63
307, 311, 313, 317, 331, 337, 347, 349, 353, 359, 367,	
373, 379, 383, 389, 397	79
401, 409, 419, 421, 431, 433, 439, 443, 449, 457, 461,	
463, 467, 479, 487, 491, 499	96
503, 509, 521, 523, 527, 541, 547, 557, 563, 569, 571,	
577, 587, 593, 599	111
601, 607, 613, 617, 619, 631, 641, 643, 647, 653, 659,	
661, 673, 677, 683, 691	127
701, 709, 719, 727, 733, 739, 743, 751, 757, 761, 769,	
773, 787, 797	141
809, 811, 821, 823, 827, 829, 839, 853, 857, 859, 863,	
877, 881, 883, 887	156
907, 911, 919, 929, 937, 941, 947, 953, 967, 971, 977,	
983, 991, 997	170

All prime numbers (2 excepted) are contained in the four following forms: viz. $8x \times 1$, $8x + 3$, $8x + 5$, and $8x + 7$.

PRIME VERTICAL, is that vertical circle, or azimuth, which is perpendicular to the meridian, and passes through the east and west points of the horizon.

PRIME VERTICALS, in dialling, or **PRIME-VERTICAL DIALS**, are those that are projected on the plane of the prime vertical circle, or on a plane parallel to it. These are otherwise called direct, erect, north, or south dials.

PRIME OF THE MOON, is the new moon at her first appearance, for about three days after her change. It means also the **GOLDEN NUMBER**, which see.

PRIMELY. *ad.* (from *prime*.) 1. Originally; primarily; in the first place; in the first intention (*South*). 2. Excellently; supremely well.

PRIMENESS. *s.* (from *prime*.) 1. The state of being first. 2. Excellence.

PRIMER. *s.* 1. An office of the blessed Virgin (*Stillingfleet*). 2. A small prayer book, in which children are taught to read.

PRIMER SEASIN, in feudal law, was a feudal burden, only incident to the king's tenants *in capite*, and not to those who held of inferior or mesne lords. It was a right which the king had, when any of his tenants *in capite* died seized of a knight's fee, to receive of the heir (provided he were of the full age), one whole year's profits of the lands if they were in immediate possession, and half a year's profits if the lands were in reversion expectant on an estate for life.

PRIMEROSE (Gilbert), a Scotch divine, minister of the French church in London, chaplain to James I. and canon of Windsor. He died 1642. He is author of Jacob's vow in opposition to the vows of monks and friars, in French, 4 vols. 4to.—the trumpet of Sion in 18 sermons, and other theological works. His son James, a physician, for some time practised at Paris, and settled in Yorkshire. He wrote several treatises *dè mulierum morbis*, 4to.—*dè circulatione sanguinis*—*ars pharmaceutica*—*dè vulgi erroribus in medicinâ*, 8vo. &c.

PRIMEVAL. **PRIMEVOUS**. *a.* (*primævus*, Lat.) Original; such as was at first (*Blackmore*).

PRIMING, in gunnery, the train of powder that is laid, from the opening of the vent, along the gutter or channel on the upper part of the breech of the gun; which, when fired, conveys the flame to the vent, by which it is further communicated to the charge, in order to fire the piece. This operation is only used on shipboard at the proof, and sometimes in garrison; for, on all other occasions, tubes are used for that purpose.

PRIMING-WIRE, in gunnery, a sort of iron needle employed to penetrate the vent or touch-hole of a piece of ordnance, when it is loaded; in order to discover whether the powder contained therein is thoroughly dry and fit for immediate service; as likewise to search the vent

and penetrate the cartridge, when the guns are not loaded with the loose powder.

PRIMING, among painters, signifies the laying on of the first coat of colour.

PRIMITIAL. *a.* (*primitius*, *primitiæ*, Latin.) Being of the first production (*Ains*).

PRIMITIVE. *a.* (*primitif*, French; *primitivus*, Latin.) 1. Ancient; original; established from the beginning (*Tillotson*). 2. Formal; affectedly solemn; imitating the supposed gravity of old times. 3. Original; primary; not derivative (*Milton*).

PRIMITIVE, in grammar, is a root or original word in a language, in contradistinction to derivative: thus, God is a primitive; godly, a derivative; and godlike, a compound.

PRIMITIVELY. *ad.* (from *primitive*.) 1. Originally; at first (*Brown*). 2. Primarily; not derivatively. 3. According to the original rule (*South*).

PRIMITIVENESS. *s.* (from *primitive*.) State of being original; antiquity; conformity to antiquity.

PRIMNESS. *s.* (from *prim*.) Affected niceness or formality.

PRIMOGENIAL. *a.* (*primigenius*, Lat.) First-born; original; primary; constituent; elemental (*Boyle*).

PRIMOGENITURE. *s.* (*primogeniture*, French.) Seniority; eldership; state or privilege of being first-born (*Gov. of the Tongue*).

PRIMOGENITURE, the right of the first-born, has among most nations been very considerable. The first-born son in the patriarchal ages had a superiority over his brethren, and, in the absence of his father, was priest to the family. Among the Jews, he was consecrated to the Lord, had a double portion of the inheritance, and succeeded in the government of the family or kingdom. It is, however, remarkable, and unquestionably shows the connection between this institution and the birth and office of our Saviour, that, if a woman's first child was a girl, neither she nor the children that came after her were consecrated.

In every nation of Europe, the right of primogeniture prevails in some degree at present, but it did not prevail always. The law which calls the elder-born to the crown, preferably to others, was not introduced into France till very late; it was unknown to the first race of kings, and even to the second. The four sons of Clovis shared the kingdom equally among themselves; and Louis le Debonnaire did the same: it was not till the race of Hugh Capet that the prerogative of succession to the crown was appropriated to the first-born.

By the ancient custom of Gavel-kind, still preserved in some parts of our island, primogeniture is of no account; the paternal estate being equally shared by all the sons.

PRIMORDIAL. *a.* (*primordium*, Latin.) Original; existing from the beginning (*Boy*).

PRIMORDIAL. *s.* (from the adj.) Origin; first principle (*More*).

PRIMORDIAN. *s.* A kind of plum.

PRIMORDIATE. *a.* (from *primordium*, Lat.) Original; existing from the first (*Boyle*).

Pultenaea Daphnoides.
or
Daphne-Pultenaea.

Primula Nivea.
or
Snowy Primrose.

PRIMROSE. See PRIMULA.

PRIMROSE (Nightly or tree). See CENOTHERA.

PRIMROSE (Peerless). See NARCISSUS.

PRIMULA. Primrose. In botany, a genus of the class pentandria, order monogynia. Capsule one-celled, with a ten-cleft mouth; corol with a cylindrical tube and pervious throat; stigma a globular head. Nineteen species; natives of Europe, four of them of our own country. The following are cultivated.

1. *P. vulgaris*. Common primrose. The flower when wild is of a pale brimstone hue; but there is a variety purple. The varieties produced by cultivation are, common yellow-flowered; white; paper-white; red; double-yellow; double-white; double-red; double-pink; double-crimson. Found wild in most parts of Europe.

2. *P. elatior*. Oxlip, or great cowslip. Leaves contracted towards the middle; wrinkled, toothed; border of the corol flat, which distinguishes it from the cowslip. Like the last, offers many varieties from variety in its colours; purple, red, golden, orange, with different shades of each.

3. *P. veris*. Common cowslip; or paigle. Border of the corol concave. The varieties are common, single, yellow cowslip; double-yellow cowslip; scarlet-cowslip; hose, and hose-cowslip. The flowers of this plant have a moderately strong and pleasant smell, and a somewhat roughish bitter taste. Vinous liquors impregnated with their flavour by maceration or fermentation, and strong infusions of them drank as tea, are supposed to be mildly corroborant, antispasmodic, and anodyne. An infusion of three pounds of the fresh flowers in five pints of boiling water is made in the shops into a syrup of a fine yellow colour, and agreeably impregnated with the flavour of the cowslip.

4. *P. farinosa*. Bird's-eye primrose. Border of the corol flat; leaves mealy underneath; sometimes found a foot and a half in height.

5. *P. longifolia*. Long-leaved bird's-eye primrose. Leaves serrate, glabrous; umbel nodding; corol with a very long tube. A native of the Alps.

6. *P. cortusoides*. Cortusa-leaved primrose. Leaves wrinkled, lobed; scape many-flowered. A native of Siberia.

7. *P. marginata*. Silver-edged primrose. Leaves obovate, tooth-serrate, edged with white: a native of Switzerland.

8. *P. auricula*. Auricula, or bear's-ear. Leaves serrate, glabrous, obovate, succulent, with mealy edges; flowers varying in colour; the most common yellow or red; not unfrequently purple, and variegated; or with a white eye powdered with meal; scape many-flowered, about as long as the leaves. A native of Switzerland, and Austria; flowers in April and May.

All these species are raised so easily by parting the roots that it is seldom worth while to

rear them from seeds. The double kinds, indeed, can only be increased, without failure, in this way: though if we want original sorts we have recourse to sowing, which should be done in boxes or large pots filled with light rich mould. If the spring should prove dry, the boxes should be frequently watered; and as the heat advances, they must be removed more into the shade. About the middle of May the plants should be transplanted into some shady borders, enriched with heats dung; they should stand at the distance of four inches, and be properly watered till they have taken root. About the end of August let the plants be transplanted, and placed in rows, and six inches asunder, into a border of light, rich earth, exposed to the east. The roots should be constantly removed, and parted, every year, and the earth of the border changed. See Nat. Hist. Pl. CXXXIV.

PRIMUM MOBILE, in the Ptolemaic astronomy, the ninth or highest sphere of the heavens, whose centre is that of the world, and in comparison of which the earth is but a point. This they will have to contain all other spheres within it, and to give motion to them, turning itself, and all them, quite round in 24 hours.

PRINCE. *s.* (prince, Fr. *princeps*, Latin.) 1. A sovereign; a chief ruler (*Milton*). 2. A sovereign of rank next to kings. 3. Ruler of whatever sex (*Camden*). 4. The son of a king. Popularly the eldest son of him that reigns under any denomination is called a prince (*Sidney*). 5. The chief of any body of men (*Pea-cham*).

PRINCE, PRINCERS, in polity, a person invested with the supreme command of a state, independent of any superior.

Prince also denotes a person who is a sovereign in his own territories, yet holds of some other as his superior; such are the princes of Germany, who, though absolute in their respective principalities, are bound to the emperor in certain services.

Prince also denotes the issue of princes, or those of the royal family. In France, before the revolution, they were called princes of the blood; and during the short continuance of the constitution of 1791, French princes. In England the king's children are called sons and daughters of England; the eldest son is created prince of Wales; the cadets are created dukes or earls as the king pleases, and the title of all the children is royal highness: all subjects are to kneel when admitted to kiss their hand; and at table, out of the king's presence, they are served on the knee.

To PRINCE. *v. n.* To play the prince; to take state (*Shakspeare*).

PRINCEDOM. *s.* (from *prince*.) The rank, estate, or power of the prince; sovereignty (*Milton*).

PRINCELIKE. *a.* (prince and like.) Becoming a prince (*Shakspeare*).

PRINCELINESS. *s.* (from *princely*.) The state, manner, or dignity of a prince.

PRINCELY. *a.* (from *prince*.) 1. Having

the appearance of one high born (*Shakspeare*).
 2. Having the rank of princes (*Sidney*). 3. Becoming a prince; royal; grand; august (*Milton*).

PRINCELY. *ad.* In a princelike manner.

PRINCE'S-FEATHER, in botany. See AMARANTHUS.

PRINCE'S-METAL, a mixture of copper and zinc. See ZINCUM.

PRINCE'S WOOD. See HAMELIA.

PRINCE'S ISLAND, a small island on the W. coast of Africa, 250 miles S.W. of Loango. Lon. 6. 40 E. Lat. 1. 49 N.

PRINCE'S ISLAND, a small island of Asia, at the S.W. extremity of the straits of Sunda, a few leagues from the coast of Java. It is very woody, and not much cleared. The inhabitants are Javanese, whose rajah is subject to the sultan of Bantam; and their customs are very similar to those of the natives about Batavia. The best anchoring place is in lon. 105. 17 E. Lat. 0. 36 S.

PRINCE OF WALES CAPE, the most western extremity of all America, hitherto known, discovered by captain Cook in 1778. Lon. 168. 5 W. Lat. 65. 46 N.

PRINCE OF WALES FORT, the most northern settlement of the Hudson's Bay Company, seated on the W. side of Hudson's Bay, at the mouth of Churchill river. Lon. 94. 7 W. Lat. 58. 47 N.

PRINCETON, a town of the United States, in New Jersey, noted for a college, founded in 1738, and called Nassau Hall. It is 42 miles N.E. of Philadelphia, and 53 S.W. of New York. Lon. 74. 34 W. Lat. 40. 22 N.

PRINCE WILLIAM HENRY'S ISLAND, an island in the Eastern Ocean, lying W.N.W. of Tench's island. It is pretty high, well wooded, and 70 miles in circuit. The natives are quite naked, and seem to be the same sort of people as those on Tench's Island, and their canoes of the same construction. It was discovered by lieutenants Ball and King, in 1790. A high mountain rising in the centre of it was called Mount Philip. Lon. 149. 30 E. Lat. 1. 32 S.

PRINCE WILLIAM HENRY'S ISLAND, an island of the South Pacific Ocean, discovered by captain Wallis, in 1767. Lon. 141. 6 W. Lat. 17. 0 S.

PRINCE WILLIAM'S SOUND, a gulf on the N.W. coast of America, so named by captain Cook, in 1778. The men, women, and children, are here all clothed in the same manner. Their ordinary dress is a sort of close robe, which sometimes reaches only to the knees, but generally down to the ancles. They are composed of the skins of various animals, and are commonly worn with the hairy side outward. The men often paint their faces of a black colour, and of a bright red, and sometimes of a blueish or leaden hue; but not in any regular figure. The women puncture or stain the chin with black, that comes to a point in each of their cheeks. Their canoes are of two sorts; the one large and open, the other small and covered: the framing consists

of slender pieces of wood, and the outside is composed of the skins of seals, or other sea animals, stretched over the wood. Their weapons, and implements for hunting and fishing, are the same as those used by the Esquimaux. Our knowledge of the animals of this part of the continent is entirely derived from the skins that were brought by the natives for sale. These were principally of bears, common and pine martens, sea otters, seals, racoons, small ermines, foxes, and the whitish cat or lynx. The birds found here were the halcyon, or great king-fisher, which had fine bright colours; the whiteheaded eagle, and the humming-bird. Few vegetables of any kind were observed; and the trees that chiefly grew about the Sound were the Canadian spruce pine, some of which are of a considerable size. Lon. 147. 21 W. Lat. 59. 33 N.

PRINCESS. *s.* (*princesse*, French.) 1. A sovereign lady; a woman having sovereign command (*Swift*). 2. A sovereign lady of rank, next to that of a queen. 3. The daughter of a king (*Shakspeare*). 4. The wife of a prince: as, *the princess of Wales*.

PRINCESS ANN TOWN, a town of the United States, in Maryland, 114 miles S. of Philadelphia. Lon. 75. 48 W. Lat. 38. 10 N.

PRINCIPAL. *a.* (*principalis*, Latin.) 1. Principally: a latinism (*Spenser*). 2. Chief; of the first rate; capital; essential; important; considerable (*Shakspeare*).

PRINCIPAL. *s.* (from the adjective.) 1. A head; a chief; not a second (*Bacon*). 2. One primarily or originally engaged; not accessory or auxiliary (*Swift*). 3. A capital sum placed out at interest (*Swift*). 4. President or governor.

PRINCIPAL POINT, in perspective, is a point in the perspective plane, upon which a line drawn from the eye perpendicular to the plane falls. It is in the intersection of the horizontal and vertical plane, and called the point of sight, and point of the eye. See PERSPECTIVE.

PRINCIPAL RAY, in perspective, that which passes perpendicularly from the spectator's eye to the perspective plane. See PERSPECTIVE.

PRINCIPALITY. *s.* (*principauté*, Fr.) 1. Sovereignty; supreme power (*Sidney*). 2. A prince; one invested with sovereignty (*Milton*). 3. The country which gives title to a prince; as, *the principality of Wales* (*Temple*). 4. Superiority; predominance (*Taylor*).

PRINCIPALLY. *ad.* (from *principal*.) Chiefly; above all; above the rest (*Newton*).

PRINCIPALNESS. *s.* (from *principal*.) The state of being principal or chief.

PRINCIPATO, a province of Naples, divided into Principato Ulteriore and Principato Citeriore, that is, the Further and Hither Principato. Principato Citeriore is bounded on the N. by Principato Ulteriore, on the W. and S. by the Mediterranean, and on the E. by Basilicata. It is 60 miles long and 30

broad; the soil fertile in wine, corn, oil, and saffron; and it has a great deal of silk, and several mineral springs. Salerno is the capital. Principato Ulteriore is bounded on the N. by the Molise and Terra-di-Lavoro, E. by Basilicata and Capitanata, S. by Principato Citeriore, and W. by the Mediterranean. It is 37 miles long and 30 broad; the soil not fertile in corn or wine, but produces chesnuts, and has excellent pastures. Benevento is the capital.

PRINCIPIATION. *s.* (from *principium*, Lat.) Analysis into constituent or elemental parts: not used (*Bacon*).

PRINCIPLE. *s.* (*principium*, Latin.) 1. Element; constituent part; primordial substance (*Watts*). 2. Original cause (*Dryden*). 3. Being productive of other being; operative cause (*Tillotson*). 4. Fundamental truth; original postulate; first position from which others are deduced (*Hooker*). 5. Ground of action; motive (*Addison*). 6. Tenet on which morality is founded (*Law*).

TO PRINCIPLE. *v. a.* (from the noun.) 1. To establish or fix in any tenet; to impress with any tenet good or ill (*South*). 2. To establish firmly in the mind (*Locke*).

PRINCIPLE (*principium*), a term frequently used for the cause, source, or origin of any thing.

In which sense we say, the principles of thinking, of willing, &c.

In physics, we must ever have recourse to a first principle, which is God.

The Manichees admit of two principles, the one of good, the other of evil; which they establish in the quality of two contrary deities, constantly opposing each other. See **MANICHEE**.

According to the doctrine of Pelagius, our own wills are the principles of our good actions, and we ourselves the principles of our good wills.

Principle is defined, among the school philosophers, to be that from which any thing is, is done, or known; *unde aliquid est, fit, aut cognoscitur*; which is a very extensive signification, and agrees to all kinds of principles.

Thus, the premises are principles, in respect of the conclusion; and thus fire and every other agent are the principles of things which they produce.

The Thomists define principle to the like effect: *id a quo aliquid procedit aliquo modo*.

Philosophers usually distinguish principles into those of being, *principia essendi*; and those of knowing, *principia cognoscendi*, or *principia rei*, and *cognitionis*.

Of the first they make two kinds; viz. principles of origination, which are those from which something proceeds really the same with the principle. And principles of dependency; in which sense, any cause may be a principle, in respect of the thing caused; or a subject, in respect of the accidents inherent in it.

The second is that from which we borrow or derive our knowledge of some other thing; or, it is that which makes the thing be known.

Such are axioms, definitions, hypotheses; such also are examples, explanations, &c.

Philosophers and mathematicians are generally agreed in admitting that there are axioms, that is, certain indemonstrable truths; which must be reckoned among the principles of human knowledge in the strictest sense. Hobbes seems to advance the contrary, when he says, in his logic, or first part of his book de Corpore, that definitions, or their parts, are the only primary propositions (*propositiones primæ*), that is, principles in an absolute and strict sense. But this doctrine of Hobbes cannot be admitted. For, however true it may be in itself, and with respect to the divine mind, it seems certain, that the human mind has never yet attained, and perhaps never will attain to a perfect analysis of its own notions in all cases. And wherever this analysis ceases, definitions cease with it; and where definitions cease, we are forced, if we would demonstrate any thing of the undefined subject, to have recourse to axioms, or to indemonstrable truths admitted by all men, though never yet demonstrated by any one. This will appear evident to those who attentively consider Euclid's Elements.

Bishop Berkeley observes very justly, that the principles of science are neither objects of sense nor imagination, but notions of relation, that is, acts of the mind. Thus, space, time, number, are not objects of sense or imagination, although the things coextended with space or time, or things numbered, be objects of sense. This is most evident in number, which is plainly different from the perception of the things numbered. Nor can the act by which we number be taught or exemplified. For instance, that act of the mind by which we conceive $1 + 1 = 2$, cannot be explained or analysed into others; and supposing it could, we must still stop somewhere, and wherever that be, there is something a disciple must have a *se, non a præceptore*, as Aristotle says. So that, strictly speaking, principles are not taught. And those who maintain them innate, are perhaps not so absurd as Locke pretends. Reflection on Tar Water, art. 264. Ibid, art. 288.

PRINCIPLES. *Principia.* In chemistry. Primary substances. According to modern chemists, this term is applied to those particles which are composed of two or more elements (see **ELEMENTS**), that may again be decomposed by the action of fire or putridity; such as water, gum, resin, &c.

PRINCIPLES (Animal). The component principles of the animal frame may be divided into constituent and elementary. The constituent principles are: 1. Water, which constitutes the greatest part of the humours, and is the vehicle of the other principles. 2. Animal gas, which consists of carbonated hydrogen, and is found not only in the blood, but in all the other fluids. 3. Inflammable gas, emitted from the large intestines, *in flatu*. 4. Animal gluten, which consists of carbon, and azot, and forms the fibres of the solid parts;

P R I N C I P L E S.

the caseous portion of the milk; and the cruor of the blood. 5. Albumen, present in the serum of the blood: 6. Jelly, found in the serum of the blood; lymph of the lymphatic vessels, and other fluids; and the interstices of all the fibres. 7. Cruor, which is the animal gluten impregnated with oxydated iron. 8. Mucus, which lubricates the *primæ viæ*; the aerial surfaces of the lungs; the parts of generation, and the urinary passages. 9. Animal oil, which fills the cells of the adipose membrane. 10. Resin, found in the bile. 11. Sebatic acid, which is present in animal oil. 12. Phosphoric acid, which enters into the composition of the animal earth of the bones, and the phosphorated salts of the urine. 13. Lactic acid, in the sugar of the serum of the milk. 14. Sugar, latent in the serum of the milk. 15. Animal earth, which is a phosphorated calx, and not only forms the greatest part of the bones, but also is found in the fibres of the soft parts, and in all the fluids. 16. Phosphorated volatile alkali, and 17. Phosphorated soda, both of which are detected in the urine. 18. Culinary salt, obtained from the urine, gastric juice, semen, and other humours.

The elementary principles of our body hitherto known, are, 1. Azot, an element which combined with hydrogen constitutes volatile alkali; with the matter of heat, azotic air; with carbon, the gluten of animal fibres. Azot is the primary element of the animal body, for it may be extracted from almost every part of the animal, by means of the nitrous acid, this having a greater affinity with the elements than the azot itself. The mucus, jelly, membranes, tendons, ligaments, and cartilages, afford it in a less degree by means of the nitrous acid. The lymph, serum of the blood, the water of hydropic patients, the liquor amnii, and cheese, give out more. The greatest quantity of azot is obtained from the coagulable lymph of the blood, and from muscle. The flesh of young animals contains less than that of old; and it is in greater quantity in sarcophagous, than in the flesh of phytophagous animals and fish. It is not probable that the azot is produced by the decomposition of the nitre; for after having performed the separation, it is capable of saturating the same quantity of salt of tartar as before. 2. The matter of heat, which enters into the composition of both solids and fluids, and which, in a separate form, constitutes the animal heat. 3. The matter of light, which in its free state produces vision, and, when compounded, enters as an element into the composition of oil and all other inflammable parts. The eyes of animals, which shine in the night-time, owe this property to the matter of light. 4. The electric matter, which enters into all bodies, and affords the phenomena of animal electricity. 5. Oxygen, which, in combination with the matter of heat, constitutes vital air; with hydrogen, forms water; with acescent bases, the acid salts of our fluids. 6. Hydrogen, which, combined with oxygen, forms water; with

azot, volatile alkali; with the matter of heat, inflammable air, which is emitted from the large intestines; and with carbon, animal gass: and lastly, combined with carbon and the sebatic acid, constitutes the oil of the adipose membrane. 7. Carbon, which, in combination with hydrogen and the sebatic acid, constitutes the oil of the adipose membrane; with hydrogen alone, animal gass: with azot, animal gluten. 8. Sulphur, which, combined with inflammable air, constitutes the hepatic air, that exhales from muscular fibres, hair, incubated eggs, animal gluten, and, according to Lavoisier, human excrement. 9. Phosphorus, which, with oxygen, forms the phosphoric acid; and, with inflammable air, phosphoric air. The lucid sweat of some men, the phosphorescence or light given out by the putrifying bodies of some animals, and the phosphorus obtained from cheese and human bones, sufficiently shew that phosphorus constitutes an element of our body. 10. Soda, or the fixed mineral alkali. 11. Potash, or the fixed vegetable alkali. Each of these is found in several of the fluids of the human body. 12. An earthy element. Of the earths, no kind is so frequently detected as the calcareous, which is found in the bones and other parts. 13. A metallic element. Of so great a number of metals, iron and manganese alone are found in an organized body, whether animal or vegetable. Iron is in greater quantity in the flesh than in the bones; but in the greatest porportion in the cruor or red part of the blood. 14. An odorous principle, perceptible in all the animal fluids; but of a peculiar kind in the human urine and excrements. 15. The nervous fluid, contained in the nerves, and which appears to be an element, *sui generis*, distinct from all known fluids, and not to be collected by art. 16. The vital principle. In all solid and fluid parts of a living body there exists an element, with properties peculiar to itself, which constitutes life; hence it is justly called vital. This principle induces a mode of union in the other elements, widely differing from that which arises from the common laws of chemical affinity. By the aid of this principle nature produces the animal fluids, as blood, bile, semen, and the rest, which can never be produced by the art of chemistry. But if, in consequence of death, the laws of vital attraction or affinity cease to operate, then the elements recovering their former properties, become again obedient to the common laws of chemical affinity, and enter into new combinations, from which new principles, or the production of putrefaction, are produced. Thus the hydrogen combining itself with the azot, forms volatile alkali; and the carbonated hydrogen, with the azot, putrid air, into which the whole body is converted. It also appears from hence why organized bodies alone, namely animal and vegetable, are subject to putridity; to which inorganic or mineral substances are in no degree liable, the latter not being compounded according to the laws of vital affinity, but only according to

those of chemical affinity. For the fatiscence or resolution of the pyrites of ferrum sulphuratum in the atmospheric air, is not putrefaction, but only the oxygen, furnished by the air, combining with the sulphur, and forming sulphuric acid. Fire, as well as putridity, separates the constituent principles of animal bodies into their elements; but these, by a peculiar law, under the action of fire again combine in a different manner, and form peculiar constituent principles, called the products of fire. Thus the hydrogen, combining with azot, is changed into volatile alkali; but with a large proportion of carbon, it forms empyreumatic oil. From what has hitherto been said, it will also appear that the true constituent principles of an animal body cannot be detected either by putrefaction or the action of fire; for by these means we only discover the elements of those principles. Thus, whenever volatile alkali is found to be generated, azot and hydrogen may be supposed to have been present in the natural state of the animal substance; and when empyreumatic oil is obtained, it may be concluded it is furnished by the hydrogen and carbon of the animal part.

PRINCOCK. *PRINCOX.* *s.* (from *prink* or *prim cock*.) A cockcomb; a conceited person; a pert young rogue: obsolete (*Shakespeare*).

PRINGLE (Sir John), an eminent physician and philosopher, was a younger son of sir John Pringle of Stichel, in the shire of Roxburgh, baronet; was born in 1707, and took the degree of M. D. at Leyden, 1730; and published there *Dissertatio Inauguralis de Marcere Senili*; 4to. After having been some years professor of moral philosophy at Edinburgh, he was in June 1745 appointed physician to the duke of Cumberland, and physician general to the hospital of the forces in Flanders, where the earl of Stair appears to have been his patron. In February 1746 Dr. Pringle, Dr. Armstrong, and Dr. Barker, were nominated physicians to the hospital for lame, maimed, and sick soldiers, behind Buckingham-house; and in April 1749 Dr. Pringle was appointed physician in ordinary to the king. In 1750 he published *Observations on the Nature and Cure of Hospital and Gaol Fevers*, in a letter to Dr. Mead, 8vo. (reprinted in 1755); and in 1752 he favoured the public with the result of his long experience in an admirable treatise under the title of *Observations on the Disorders of the Army in Camp and Garrison*, 8vo. On the 14th of April 1752 he married Charlotte, second daughter of Dr. Oliver, an eminent physician at Bath. In 1756 he was appointed jointly with Dr. Wintringham (afterwards sir Clifton Wintringham, bart.) physician to the hospital for the service of the forces of Great Britain. After the accession of his present majesty, Dr. Pringle was appointed physician to the queen's household, 1761; physician in ordinary to the queen in 1763, in which year he was admitted of the college of physicians in London; and

on the 5th of June 1766 he was advanced to the dignity of a baronet of Great Britain. In 1772 he was elected president of the royal society, where his speeches for six successive years, on delivering the prize-medal of sir Godfrey Copley, gave the greatest satisfaction. Sir John Pringle in 1777 was appointed physician extraordinary to the king. He was also a fellow of the college of physicians at Edinburgh, and of the royal medical society at Paris; member of the royal academies at Paris, Stockholm, Gottingen, and of the philosophical societies at Edinburgh and Haerlem; and continued president of the royal society till Nov. 1778, when he resigned immediately after delivering the gold medal to Dr. Hutton on account of his very ingenious paper on the force of fired gunpowder. The causes of this resignation we shall not here detail; but refer the reader to the interesting memoirs of sir John, given by Dr. Hutton in the 2d vol. of his well-known Dictionary.

Though sir John Pringle thus quitted his particular relation to the royal society, and did not attend its meetings so constantly as he had formerly done, he still retained his literary connections in general. His house continued to be the resort of ingenious and philosophical men, whether of his own country, or from abroad; and he was frequent in his visits to his friends. He was held in particular esteem by eminent and learned foreigners, few of whom came to England without waiting upon him, and paying him the greatest respect. He treated them, in return, with distinguished civility and regard. When a number of gentlemen met at his table, foreigners were usually a part of the company.

In 1780 sir John spent the summer on a visit to Edinburgh; as he did also that of 1781; where he was treated with the greatest respect. In this last visit he presented to the royal college of physicians in that city the result of many years labour, being ten folio volumes of *Medical and Physical Observations*, in manuscript, on condition that they should neither be published, nor lent out of the library of the college on any account whatever. He was at the same time preparing two other volumes, to be given to the university, containing the formulas referred to in his annotations. He returned again to London, and continued for some time his usual course of life, receiving and paying visits to the most eminent literary men, but languishing and declining in his health and spirits, till the 18th of January 1782, when he died, in the 75th year of his age; the account of his death being every where received in a manner which shewed the high sense that was entertained of his merit.

Among this worthy physician's communications to the royal society, the following are the principal: 1. *Some Experiments on Substances resisting Putrefaction*, *Phil. Trans.* No. 495, p. 580; and No. 496, p. 525, 550; reprinted, with additions, in *Martin's Abridgment*, vol. xi. p. 1365. 2. *Account of some Persons seized*

with the Gaol Fever by working in Newgate, and of the Manner by which the Infection was communicated to one entire Family, vol. xlviii. p. 42. At the request of Dr. Hales, a copy of this useful paper was inserted in the Gentleman's Magazine, 1753, p. 71, before its appearance in the Transactions. 3. A remarkable Case of Fragility, Flexibility, and Dissolution of the Bones, ib. p. 297. 4. Account of the Earthquakes felt at Brussels, vol. xlix. p. 546. 5. Account of sinking of a River near Pontypool, in Monmouthshire, ib. p. 547. 6. Account of an Earthquake felt Feb. 18, 1756, along the Coast of England, between Margate and Dover, ib. p. 579. 7. Account of the Earthquake felt at Glasgow and Dumbarton; also of a Shower of Dust falling on a Ship between Shetland and Iceland, ib. p. 509. 8. Several Accounts of the Fiery Meteor which appeared on Sunday, November 26, 1758; between eight and nine at night, vol. l. p. 218. 9. Account of the Virtues of Soap in dissolving the Stone, in the Case of the reverend Mr. Matthew Simson, ib. p. 221. 10. Account of the Effects of Electricity in Paralytic Cases, ib. p. 481. And see a letter to him on that subject from professor Winthorp. Some Account of the Success of the Vitrum Ceratum Antimonii, was printed in the Edinburgh Medical Essays, vol. v.

To PRINK. *v. n.* (*pronken*, Dutch.) To prank; to deck for show (*Art of Tormenting*).

PRINOS. Winter-berry: In botany, a genus of the class hexandria, order monogynia. Calyx six-cleft; corol one-petalled, wheel-shaped; berry six-seeded. Seven species; natives of America and the West Indies; of which the two following are cultivated.

1. *P. verticillata*. Deciduous winter-berry.

2. *P. glabra*. Ever-green winter-berry. Both shrubby plants, with flowers at the end of the branches, usually blue or purple, appearing in July and August.

To PRINT. *v. a.* (*imprimer*, *empreint*, Fr.)

1. To mark by pressing any thing upon another (*Dryden*). 2. To impress any thing, so as to leave its form (*Roscommon*). 3. To form by impression (*Shakspeare*). 4. To impress words or to make books, not by the pen, but the press (*Pope*).

To PRINT. *v. n.* 1. To use the art of typography (*Shakspeare*). 2. To publish a book (*Pope*).

PRINT. *s.* (*empreinte*, French.) 1. Mark or form made by impression (*Chapman*). 2. That which being impressed leaves its form: as, a *butter print*. 3. Pictures cut in wood or copper to be impressed on paper. 4. Picture made by impression (*Waller*). 5. The form, size, arrangement, or other qualities of the types used in printing books (*Dryden*). 6. The state of being published by the printer (*Shakspeare*). 7. Single sheet printed for sale; a paper something less than a pamphlet (*Ad.*). 8. Formal method. A low word (*Locke*).

PRINTER. *s.* (from *print*.) 1. One that prints books (*Digby*). 2. One that stains linen with figures.

PRINTING, the art of making an impression upon one body by pressing it with another. This art, in some way or other, has been known in all ages. It has been done upon wax, upon plaster, upon iron, by the ancients; their seals, their rings, their money, prove it. It has been done with wooden blocks upon cotton and silk by the Indians. Printing, therefore, in this limited sense, was common to all nations. This art is now divided into four distinct branches: 1. Common, or letter-press printing. 2. Rolling press printing. 3. Calico-printing. 4. Stereotype-printing.

Printing by letter-press is the most curious branch of the art, and demands the most particular notice. It has been often remarked, that as seven cities in Greece disputed for the birth of Homer, so three cities in Europe, Haerlem, Strasbourg, and Mentz, claim the honour of the invention of printing.

Without entering minutely into the disputes which have long agitated the minds of those who have felt a particular interest in this investigation, we state it as our opinion, that Guttemberg was the inventor of the art of printing by moveable types; that he began the art at Strasbourg, and perfected it at Mentz. In this opinion, the earliest writers who mention printing are all agreed.

That the first attempts at printing were made at Strasbourg is, we think, incontestably proved by the following circumstance. John Guttemberg entered into a partnership with Andrew Drizehen-nius, John Riff, and Andrew Heilmann, all citizens of Strasbourg, binding himself to discover to them some important secrets, whereby they should make their fortunes. Each at first contributed eighty florins, and afterwards 125. The workshop was in the house of Andrew Dritzehen, who died. Guttemberg immediately sent his servant Beildeck to Nicholas, the brother of the deceased, to request him to suffer no one to enter the workshop, least the secret should be discovered, and the forms stolen. But this had already been done. This theft, and the claim which Nicholas made to succeed to his brother's share, occasioned a lawsuit, and the evidence of the servant affords explicit and incontrovertible proof in favour of Guttemberg, as the first who practised the art of printing with moveable types. The document, containing the account of this trial, &c. is dated 1439. It was published in the original German, with a Latin version, by Schopflin, in his *Vindiciae Typographicae*. M. Lambinet, in his *Recherches Historiques sur l'Origine de l'Art de l'Imprimerie*, published at Paris a few years ago, says, that the German is obscure, and that every one will interpret the equivocal words in favour of his own opinion. It is, however, manifest that Guttemberg expressly ordered that the forms should be broken up, and the characters dispersed; a fact clearly proving, that the art of printing was at that time a secret, and that moreover it was performed with moveable types. Guttemberg, after having sunk what he and his associates had embarked in this speculation, returned to Mentz, where he was born, and succeeded better in a partnership with Fust.

The evidence in favour of Guttemberg appearing to us decisive, we shall not enter into any examination of the claims advanced by the other candidates for the honour of being the inventor of the art of letter-press printing. The names of those persons were John Fust, Mentz; John

PRINTING.

Mental, of Strasbourg; and L. John Koster, of Haerlem. When the city of Mentz was taken by Adolphus, count of Nassau, in 1462, Fust, and Schoeffer, servant and son-in-law to Fust, suffered materially with their fellow townsmen. Their associates and workmen dispersed to seek their fortunes, and the art was thus diffused over Europe. When it was first established at Paris, the copiers, finding their business so materially injured, presented a memorial of complaint to the parliament, and that tribunal, as superstitious as the people, who took the printers for conjurers, had their books seized and confiscated. Louis XI. who, bad as he was, was the friend and patron of letters, forbade the parliament to take any farther cognizance of the affair, and restored their property to the printers.

The art of printing now began to spread itself over a great part of Europe with astonishing rapidity. It was practised at Rome in the year 1467, and the year following it was introduced into England by Thomas Bouchier, archbishop of Canterbury, who sent W. Turner, master of the robes, and W. Caxton, merchant, to the continent to learn the art. Turner and Caxton met with one Corseilles, an under-workman, whom they bribed with considerable presents and large promises, to come over to England, and instruct them in the art. This business having been accomplished, a press was set up at Oxford, which was afterwards removed to St. Albans, and after that to Westminster Abbey. The learned Dr. Conyers Middleton, and others, are inclined to doubt the truth of this part of the history of printing. It is certain, that Caxton did not return immediately to England, but continued some time on the continent, following the business of a printer. Indeed, both the origin and the history of the first introduction of the art of printing into this country are involved in doubt and obscurity, and nothing has ever yet been published perfectly satisfactory on this subject. We will, therefore, proceed to an account of

The method of printing.—The workmen employed in this art are compositors and pressmen. The first are those persons whose business it is to range and dispose the letters into words, lines, pages, &c. The pressmen are those who, properly speaking, are the printers, as they take off the impressions from the letters after they are prepared for that purpose by the compositors. The types being provided for the compositor, he distributes each kind, or sort, by itself, into small cells or boxes, made in two wooden frames, called the cases; the upper-case and the lower-case. The cells in the upper-case are ninety-eight in number; those of the lower-case are fifty-four.

The upper-case contains two alphabets of capitals; large, or full capitals, and small capitals. They also contain cells for the figures, the accented letters, the characters used in references to notes, &c.; and one cell, being a middle one in the bottom row, for the small letter, k. The capitals in this case are disposed alphabetically.

The lower-case is appropriated to the small letters, the double letters, the points, parentheses, spaces, and quadrats. The boxes of the lower-case are of different sizes; the largest being for the letters most in use; but the arrangement is not in this instance alphabetical, those letters oftenest wanted being placed nearest to the compositor's hand. As there is nothing on the outside of the boxes to denote the letters they respectively contain, it is curious to observe the

dexterity manifested by the compositor in finding and taking up the letters, as he wants them, from the different cells. Each case is placed in an inclined direction, that the compositor may reach the upper-case with ease.

The instrument in which the letters are set is called a composing-stick, which consists of a long plate of brass or iron, on the side of which arises a ledge, which runs the whole length of the plate, and serves to support the letters, the sides of which are to rest against it. Along this ledge is a row of holes, for introducing a screw to lengthen or shorten the line, by moving the sliders farther from, or nearer to, the shorter ledge at the end of the composing stick. Where marginal notes are required, the two sliding pieces are opened to a proper distance from each other. Before the compositor begins to compose, he puts a thin slip of brass plate, called a rule, cut to the length of the line, and of the same height as the letter, in the composing stick, parallel with the ledge, against which the letters are intended to bear. The compositor being thus furnished with an instrument suited to hold the letters as they are arranged into words, lines, &c. he places his copy on the upper-case, just before him, and holding the stick in his left hand, his thumb being over the slider, with the right he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them, with his left thumb, by pressing them against the slider, the other hand being constantly employed in setting in other letters. Having in this manner composed a line, he takes the brass rule from behind it, places it before the letters of which it is composed, and proceeds to compose another line in the same manner. But before he removes the brass rule, he notices whether the line ends with a complete word, or with an entire syllable of a word, including the hyphen that is put to denote the division, when a word is divided into syllables. If he finds that his words exactly fill the measure, he has nothing more to do with that line, but proceeds with the next. But if he finds the measure not entirely filled at the ending of a word or syllable, he puts in more spaces, diminishing the distances between the words, until the measure is full; and this operation, which is called justifying, is done in order that all the lines in the composing-stick may be of equal length. Much depends upon exactness in justifying; and great care is taken by expert compositors that the lines are neither too closely wedged into the composing stick, nor yet loose and uneven.

The spaces are pieces of metal, of various thicknesses, exactly shaped like the shanks of the letters. They are used to regulate the distances between the words.

When the composing-stick has been filled with lines, being generally in number about ten or twelve, the compositor empties upon a thin board called a galley, being of an oblong shape, with a ledge on two sides, and a groove, to admit a false bottom. When the compositor has filled and emptied his stick until he has composed a page, he ties it up with a piece of packthread, and removes it from the galley, either to the imposing-stone, or to such other safe and convenient place as he may think proper. And in this manner he proceeds until he has composed as many pages as are required to make a sheet, or, in some instances, a half-sheet. He then proceeds to arrange the pages on the imposing-stone, which is a very large oblong stone, of about five or six inches

PRINTING.

in thickness. The pages are so arranged, that, when they are printed, they may be folded so as to follow each other regularly. Great care, and some ingenuity, is requisite in the imposing of a sheet or half-sheet, particularly of works in sizes less than folio or quarto. In Stower's Printer's Grammar, a very excellent and copious work on the subject of printing, are given upwards of fifty schemes of imposition, of sheets of almost every possible size.

Having laid down or disposed the pages in right order on the imposing stone, the compositor proceeds to what is called dressing the chases. The chase is a rectangular iron frame, of different dimensions, according to the size of the paper to be printed; having two cross pieces, of the same metal, called a long and short cross, mortised at each end so as to be taken out occasionally. By the different situations of these crosses the chase is fitted for different volumes; for folios, quartos, octavos, &c. To dress the chase, a set of furniture is necessary, consisting of small slips of wood of different dimensions. The first thing to be done, is to lay the chase over the pages; after this, that part of the furniture called gutter-sticks, are placed between the respective pages. Then another part of the furniture called reglets are placed along the sides of the crosses of the chase. The reglets are of such a thickness as will let the book have proper margins after it is bound. Having dressed the inside of the pages, the compositor proceeds to do the same with their outsides, by putting side-sticks and foot-sticks to them. Thus the pages being placed at proper distances, they are all untied, and fastened together by small wooden wedges, called quoins. These small wedges, being firmly driven up the sides and feet of the pages, by means of a mallet, and a piece of hard wood called a shooting-stick, all the letters are fastened together. The work in this condition is called a form, and is ready for the pressman, who lays it upon the press, for the purpose of pulling a proof. When a proof is pulled, the form or forms are rubbed over with a brush, dipped in ley, made of pearl-ash and water; they are then carefully taken off the press, and the proof and forms delivered to the compositor's further care.

As it is impossible for the most careful compositor so to compose all his sheets as that they shall not require to be carefully read and corrected before they are finally worked-off, the next thing to be done is to put the proof, along with the copy from which it has been composed, into the hands of the reader or corrector, whose business is to read over the whole proof two or three times with great care and attention, marking such errata in the margin of every page as he shall observe.

The corrections are always placed against the line in which the faults are found. There are different characters used to denote different corrections: thus ~ is put to signify that a word is divided that ought to be in one, as *person* instead of *person*; a mark resembling the Greek theta θ is put for *dele*, to intimate that something, as a point, letter, word, &c. dashed in that line, is to be taken out. If any thing is to be inserted, the place of insertion is marked with a caret, $\wedge$, and the thing to be inserted written in the margin. Where a space is wanting between two words, or letters, that are intended to be separated, a parallel line must be drawn where the separation ought to be, and a mark, somewhat resembling a sharp in music $\sharp$, placed in the margin. An inverted letter or word is noticed by making

a dash under it, and a mark, nearly resembling the *dele* character reversed.

Mr. Stower observes, that marking turned letters tries a corrector's skill in knowing the true formation of them; without which it would be better to mark them in the same manner as they do wrong letters, which is done by dashing out the wrong letter, and writing the right one in the margin, unless they are very sure that they can distinguish b, d, n, o, p, q, s, u, x, z, when they are turned, from the same letters with their nick the right way. Where a space rises up between two words, it is noticed by a cross + in the margin. When any thing is transposed it is denoted thus:

1 4 3 2
~~~~~  
You                      merit                      your                      mistake

for *You mistake your merit*; and in the margin is added *tr.* for transposition. Where a new paragraph is required, a line in the shape of a crochets [ is made, and the same mark placed in the margin; also where a paragraph ought not to have been made, a line is drawn from the broken-off matter to the next paragraph; and in the margin is written *No break*. If Italic letters are to be changed for Roman, or *vice versa*, a line is drawn, thus —, under the letters, and *Rom.* or *Ital.* is written in the margin. Where words have been struck out that are afterwards approved of, dots are marked under such words, and in the margin is written the word *slet*. Where the punctuation is required to be altered, the semicolon, colon, and period, are encircled in the margin. The comma and other points are marked as letters and words, viz. with a long oblique line immediately before them; which line is intended to separate the different corrections from each other that occur in the same line. When letters of a different fount or size are improperly introduced into the page, they are noticed by a small dash drawn through them, and the letters *w. f.* in the margin. There are some other marks used in correcting; such as  $\surd$  for superior; where it is necessary to insert the apostrophe, the star, or other reference marks, and superior letters: *Cap.* for capitals, *L. C.* for lower case, &c.

After a proof sheet has been read, and the errata thus noticed by the corrector, or, as he is more usually called, the reader, it is again put into the hands of the compositor, who proceeds to correct in the metal what has been marked for correction in the proof. He then unlocks the form on the imposing stone, by loosening the quoins or wedges which bound the letters together. He then casts his eye over one page of the proof, noticing what letters, &c. are required. Having gathered as many corrections, from the cases, between the thumb and fore-finger of his left hand, as he can conveniently hold, and an assortment of spaces, on a piece of paper, or in a small square box with partitions in it, he takes a sharp-pointed steel bodkin in his right hand. Placing the point of the bodkin at one end of the line, and the fore-finger of his left hand against the other, he raises the whole line sufficiently high to afford him a clear view of the spacing. He then changes the faulty letters or words, and alters his spaces before he drops the line.

The first proof being corrected, another is pulled, to be again put into the hands of the reader, or sent to the author for examination. This proof being read and corrected as before, a revise is pulled, to see whether all the errors marked in the

# PRINTING.

last proof are properly corrected. When the sheet is supposed to be correct, the forms are given to the pressman, whose business it is to work them off when they are so prepared and corrected: in doing which four things are required; paper, ink, balls, and a press. The paper is prepared for use by being dipped, a few sheets at a time, in water, and afterwards laid in a heap sheet over sheet, to make the water penetrate equally into every sheet, a thick deal board is laid upon the heap, on which is placed heavy weights according to the size of the heap. The reason why the paper is to be wetted before it is in a fit state to be printed upon, is, that it may be made sufficiently soft to adhere closely to the surface of the letter, and take up a proper quantity of ink, that it may receive a fair and clear impression. It is also necessary to wet the paper, lest its stiff and harsh nature, when dry, should injure the face of the letters.

The ink used by printers has already been treated of in the article *INK*, which see. The manufacture of good common ink seems to be as yet but very imperfectly understood. That used in fine printing has been more attended to, and many of our best printers are now able to produce impressions in a great degree free from that offensive brown cast which is to be observed in many books printed with what is called common ink.

The balls used in laying the ink on the forms are a kind of wooden funnels, with handles, the cavities of which are stuffed with wool or hair, and covered over with a pelt prepared for the purpose. One skin generally makes two proper sized balls. When the skin has been sufficiently soaked in urine, which will take about fourteen or fifteen hours, it is taken out and curried, by putting it round an iron called a currying iron, or round some upright post: the pressman taking hold of each end of it, and drawing it with as much force as possible backwards and forwards, till it is rendered soft and pliable. He then cuts the skin exactly in two, puts them under his feet, and continues to tread them till they are so dry as to stick to the foot in treading. The skin is then laid on a board or flat stone, and stretched as much as possible by rubbing the ball-stock upon it. It is then nailed upon the ball-stock in plaits about an inch wide, thrusting in as much wool as the cavity of the stock and the skin will conveniently hold. If, however, too much wool were to be put in, it would render the balls hard and difficult to work with. If too little wool is in the balls, they soon flap and wrap over into wrinkles, so as to prevent an equal distribution of the ink on their surface. When the balls are thus knocked up, as it is termed, they are dipped in urine, and scraped with a blunt knife until they are perfectly clean; they are then dried with a clean sheet of stout paper, and patted with the hand until no moisture remains on the surface. The balls, when they are completed, have much the shape and appearance of a very large mallet, used by stone-masons, except that their surface is much broader and rounder.

The press is a curious and complex machine, for which and its use, see a succeeding article.

**PRINTING (Stereotype).** Perhaps it would not have been improper to have treated of stereotype printing even before that of common printing: for the first ideas of this art were certainly anterior to those of printing by moveable types.

The method of printing linen and paper for hangings has been known in the east from time immemorial. Printing from wooden blocks, by the Jesuits, has been practised above sixteen hundred

years in China. According to this plan, when an author chooses to print his work, he has it fairly transcribed upon a thin and transparent paper. Each leaf is then reversed and fastened upon a smooth block of hard wood, upon which the engraver cuts the characters, in relief. There must be, therefore, a separate block for every page.

At the end of the fourteenth and beginning of the fifteenth century, the Italians, Germans, Flemings, and Dutch, began at the same time to engrave on wood and copper: but the previous advances had been gradual. The inscriptions in relief, upon monuments and altars, in the cloisters and over church porches, served as models for block-printing. The letters upon painted windows greatly resemble those in the books of images. The invention of cards was an intermediate step. Bullet, in his *Recherches Historique sur les Cartes à jouer*, has proved from old chronicles, in particular from that of Pettit-Jean de Sanitre, from edicts civil and ecclesiastical, and from the figures of the cards, that they were invented towards Charles the Fifth's reign, about the year 1376. By the shape of the crowns, and the sceptres with the *fleur de lis*, he infers that the French invented them. They soon were introduced into Spain, Italy, Germany, and England. The names of the suits seem rather to imply a Spanish or Italian origin. At first the cards were painted; about the year 1400 a method was devised of printing them from blocks. To this we may directly trace the art of printing. The books of images form the next step. These also were printed from wooden blocks; one side of the leaf only is impressed, and the corresponding text is placed below, beside, or proceeding from the mouth of the figure. Of these scarce books M. Lambinet mentions seven: 1. *Figuræ typicæ veteris atque antitypicæ novi testamenti*. This is the work which in Germany is called the Bible of the Poor, because it was originally designed as an abridgment of the Bible for those who could not purchase the whole scriptures in manuscript, and who probably could not read. There is one copy of this work in the Bodleian Library, and another at Christ's College, Cambridge. 2. *Historia S. Joannis Evangelistæ, ejusque visiones apocalypticæ*. 3. *Historia seu Providentia Virginis Mariæ, ex cauto canticorum*. 4. *Ars moriendi*. 5. *Ars memorandi notabilis per figuras Evangelistarum*. 6. *Donatus, seu grammatica brevis in usum scholarum conscripta*. It is not easy to conceive how this can be classed among the books of images. 7. *Speculum humanæ salvationis*. There is said to be an English translation of this work. Two other books of images, the *Twrdanck*, and the *Triumpf-wagen*, are posterior to the common use of printing. It is clear, therefore, from the cotton and silk printing of the Indians, the Chinese block-printing, and these books of images; and perhaps, also, from the bardic mode of writing, who cut their poems upon bars of wood, arranged like a gridiron, and which they called carrying a book, that the idea of stereotype printing is by no means of modern origin. That it was prior to the art of printing with moveable types there can be no doubt; since this latter mode of printing was first suggested by the Catholicon, which was printed with wooden tablets, in a series, and composed in forms. This mode of printing, except in China, where it is still practised, was laid aside soon after the invention of the common letter-press printing.

The history of the invention of modern stereo-

# PRINTING.

type is, like that of common-printing, involved in some obscurity as to the name of the person to whom justly belongs the honour of an invention so useful and curious. Mr. Andrew Tilloch, the worthy and ingenious editor of the *Philosophical Magazine*, has given the following extract, translated from *Ni-we Algemein Konst en Letter Bode*, 1798, No. 232, which deserves particularly to be noticed. "Above a hundred years ago the Dutch were in possession of the art of printing with solid or fixed types, which in every respect was superior to that of Didot's stereotype. It may, however, be readily comprehended that their letters were not cut in so elegant a manner, especially when we reflect on the progress which typography has made since that period." Samuel and J. Leuchtmann, booksellers at Leyden, have still in their possession the forms of a quarto Bible, which were constructed in this ingenious manner. Many thousand impressions were thrown off, which are in every body's hand, and the letters are still good.

"The inventor of this useful art was J. Vander Mey, father of the well-known painter of that name. About the end of the sixteenth century he resided at Leyden. With the assistance of Muller, the clergyman of the German congregation there, who carefully superintended the correction, he prepared and cast the plates for the above-mentioned quarto Bible. This Bible he published also in folio, with large margins, ornamented with figures; the forms of which are still in the hands of Elwe, bookseller, at Amsterdam; also an English New Testament, and Schaaf's Syriac Dictionary; the forms of which were melted down: likewise a small Greek Testament, in 18mo.

"As far as is known, Vander Mey printed nothing else in this manner; and the art of preparing solid blocks was lost at his death, or at least was not afterwards employed." The Dutch editor supposes that the reason Vander Mey's invention was dropped was, that "though this process in itself is very advantageous, it is far more expensive than the usual method of printing, except in those cases where such works are to be printed as are indispensably necessary, and of standing worth." Mr. Tilloch, however, is of a directly contrary opinion.

In the year 1781 was printed, by and for J. Nichols, London, a very interesting pamphlet, entitled *Biographical Memoirs of William Ged*; including a particular account of his progress in the art of block-printing. The first part of the pamphlet was printed from a MS., dictated by Ged some time before his death; the second part was written by his daughter, for whose benefit the profits of the publication were intended; the third is a copy of proposals that had been published by Mr. Ged's son, in 1751, for reviving his father's art, and to the whole is added Mr. Mores's Narrative of Block Printing.

It appears from this publication, that, in the year 1725, Mr. Ged began to prosecute plate-printing. In 1727, he entered into a contract with a person who had a little capital, but who, on conversing with some printer, got so intimidated, that, at the end of two years, he had laid out only twenty-two pounds. In 1729, he entered into a new contract with a Mr. Fenner, Thomas James, a type-founder, and John James, the architect. Sometime after, a privilege was obtained from the University of Cambridge, to print bibles and prayer-books; but it appears, that one of his partners was actually averse to the success of the plan, and engaged such people for the work as he

thought most likely to spoil it. A straggling workman, who had wrought with them, informed Mr. Mores, that both bibles and common prayer-books had been printed; but that the compositors, when they corrected one fault, made purposely half a dozen more; and the pressmen, when the masters were absent, battered the letter in aid of the compositors. In consequence of these base proceedings, the books were suppressed by authority, and the plates sent to the King's printing-house, and from thence to Mr. Caslon's foundry. "After much ill usage," says Mr. Tilloch, "Ged, who appears to have been a person of great honesty and simplicity, returned to Edinburgh. His friends were anxious that a specimen of his art should be published, which was at last done by subscription. His son, James Ged, who had been apprenticed to a printer, with the consent of his master set up the forms in the night-time, when the other compositors were gone, for his father to cast the plates from; by which means Sallust was finished in 1736." Mr. Tilloch has not only a copy of this work, but also the plate of one of the pages. Besides Sallust, Mr. Tilloch has another work, printed some years after from plates of Mr. Ged's manufacture. The book is *The Life of God in the Soul of Man*, printed on a writing pot, 12mo. and with the following imprint: "Newcastle, printed and sold by John White, from plates made by William Ged, Goldsmith in Edinburgh, 1742."

Fifty years after the invention of plate-printing by Mr. Ged, Mr. Tilloch made a similar discovery, without having, at the time, any knowledge of Ged's invention. In perfecting the invention, Mr. Tilloch had the assistance and joint labour of Mr. Foulis, printer to the University of Glasgow. After great labour, and many experiments, these gentlemen "overcame every difficulty, and were able to produce plates, the impressions from which could not be distinguished from those taken from the types from which they were cast." "Though we had reason to fear," says Mr. Tilloch, "from what we [afterwards] found Ged had met with, that our efforts would experience a similar opposition, from prejudice and ignorance, we persevered in our object for a considerable time, and at last resolved to take out patents for England and Scotland, to secure ourselves, for the usual term, the benefits of our invention; for the discovery was still as much our own as if nothing similar had been practised before. Ged's knowledge of the art having died with his son, whose proposals for reviving it, published in 1751, not having been followed with success, he went to Jamaica, where he died. The patents were accordingly obtained; nay, they are even expired; and yet we hear people, who only began their stereotype labours yesterday, talking to themselves the merit of being the first inventors!" "Owing to circumstances of a private nature;" not, however, connected with the stereotype art, the business was laid aside for a time; and Mr. Tilloch having removed from Glasgow to London, the concern was dropped altogether; not, however, till several small volumes had been stereotyped and printed, under the direction of Messrs. Tilloch and Foulis.

Some time elapsed after this, when Didot, the celebrated French printer, applied the stereotype art to logarithmic tables, and afterwards to several of the Latin classics, and to various French publications. It has been said, by the French, that the merit of the invention properly belongs to Didot; but by what we have already laid before our readers, it is evident this cannot have been the case.

# PRINTING.

Some years after Mr. Tilloch had given up the prosecution of this art, Mr. Wilson, a printer of respectability in London, engaged with earl Stanhope for the purpose of bringing it to perfection, and eventually to establish it in this country. His lordship, it is said, received his instructions from Mr. Tilloch, and had afterwards the personal attendance of Mr. Foulis, for many months, at his seat at Chevening, where his lordship was initiated in the practical part of the operation.

After two years application, Mr. Wilson announced to the public "that the genius and perseverance of earl Stanhope," whom he styles "the Right Honourable Inventor" had overcome every difficulty; and that accordingly, the various processes of the stereotype art had been so admirably contrived, combining the most beautiful simplicity with the most desirable economy, the *ne plus ultra* of perfection with that of cheapness, as to yield the best encouragement to the public for looking forward to the happy period when an application of this valuable art to the manufacture of books would be the means of reducing the price of all standard works at least thirty, and in many cases fifty per cent.

In January, 1804, the stereotype art, (with the approbation of lord Stanhope,) was offered by Mr. Wilson to the university of Cambridge, for their adoption and use in the printing of bibles, testaments, and prayer-books, upon certain terms and conditions highly advantageous to Mr. Wilson; for with his lordship's characteristic generosity, earl Stanhope has uniformly declined to accept even the reimbursement of any part of the monies by him expended in the prosecution of this ingenious art. Some differences, however, arising between Mr. Wilson and the syndics of the university, the contract was dissolved; and Mr. Wilson published his case in a stereotyped pamphlet, entitled *Arbitration between the University of Cambridge and Andrew Wilson*.

That Mr. Wilson might make out his case more clearly, he has given a computation of the nonpareil bible,—showing the expenditure by both methods of printing, upon composition, reading, wear of type, and charge of composition; and upon paper, press-work, charges on press-work, and insurance. This computation is, of course, much in favour of the stereotype art; amounting indeed to nearly one half, or fifty per cent. saved by the new method. In addition to the saving attributed to stereotype printing, it is said that, as every page of the most extensive work has a separate plate, all the pages of the said work must be equally new and beautiful: which cannot be the case with single types, which are distributed and recomposed several times over in the course of a large work. The stereotype art also, it is said, possesses a security against error. This advantage is much insisted on by the friends of the art; but with what consistency, we confess, does not immediately appear: for, strange as it may seem, after all the care that we may naturally suppose was taken to render Mr. Wilson's pamphlet a model of stereotype perfection, it is still not without its errata. The pamphlet consists of about forty-four pages; and on the forty-first page, in a line containing only two monosyllables, there is an error: viz. *void* for *void*. There are one or two other trifling inaccuracies in the pamphlet.

Indeed, as every work hitherto stereotyped clearly manifests, it is not possible that first editions of

works should be more correct when stereotyped than when printed in the common way; and it ought not to be forgotten that an error stereotyped in the first edition is perpetuated through every subsequent edition. It is said, that stereotype plates admit of alteration: this, however, if carried to any extent, must be attended with a very considerable expense.

In short, we think that the stereotype art has much the advantage of common printing in standard books of very extensive circulation and constant demand, and wherein no alteration, as to plan or size, is allowed ever to take place: but for the common and most general purposes of the art of printing, the method by moveable types is incomparably the best.

PRINTING PRESS, the apparatus by means of which the impression of the letters in a form is made upon the previously blank sheet. The body of this machine, according to the common construction, consists first of two strong vertical posts, *a, a*, (pl. 144, fig. 2) called cheeks, and joined together by four cross-pieces; the cap *b*; the head *c*, which is moveable, being partly sustained by two iron pins or long bolts that pass the cap; the till or shelf *d d*, by which the spindle and its apparatus are kept in their proper position; and the winter *e*, which bears the carriage, and sustains the effort of the press beneath. The spindle *f* is an upright piece of iron pointed with steel, having a male screw which goes into the female one in the head about four inches. Through the eye *g* of this spindle is fastened the bar *k*, by which the pressman makes the impression. The spindle passes through a hole in the middle of the till; and its point works into a brass pan or nut, supplied with oil, which is fixed to an iron plate let into the top of the platten. The body of the spindle is sustained in the centre of an open frame of polished iron, 1, 1, 2, 2, 3, 3, fixed to it in such a manner as without obstructing its free play, to keep it in a steady direction; and at the same time to serve for suspending the platten. This frame consists of two parts: the upper called the garter, 1, 1; the under, called the crane, 2, 2. These are connected together by two short legs or bolts, 3, 3; which being fixed below in the two ends of the crane, pass upward, through two holes in the till, and are received at top into two eyes at the ends of the garter, where they are secured by screws. The carriage *l* is placed a foot below the platten, having its fore-part supported by a prop called the fore-stay, while the other rests on the winter. On this carriage, which sustains the plank, are nailed two long iron bars or ribs; and on the plank are nailed short pieces of iron or steel called cramp irons, equally tempered with the ribs, and which slide upon them when the plank is turned in or out. Under the carriage is fixed a long piece of iron called the spit, with a double wheel in the middle, round which leather-girts are fastened, nailed to each end of the plank: and to the outside of the spit is fixed a rounce *m*, or handle to turn round the wheel. Upon the plank is a square frame or coffin, in which is enclosed a polished stone on which the form *n* is laid; at the end of the coffin are three frames, viz. the two tympan and frisket: the tympan *o* are square, and made of three slips of very thin wood, and at the top a piece of iron still thinner; that called the outer tympan is fastened with hinges to the coffin: they are both covered with parchment; and between the two are placed blankets, which are necessary to take off the impression of the

# PRINTING.

letters upon the paper. The frisket *p* is a square frame of thin iron, fastened with hinges to the tympan: it is covered with paper cut in the necessary places, that the sheet, which is put between the frisket and the great or outward tympan, may receive the ink, and that nothing may hurt the margins. To regulate the margins, a sheet of paper is fastened upon this tympan, which is called the tympan sheet; and on each side is fixed an iron point, which makes two holes in the sheet; which is to be placed on the same points when the impression is to be made on the other side. In preparing the press for working, the parchment which covers the outer tympan is wetted till it is very soft, in order to render the impression more equable; the blankets are then put in, and secured from slipping by the inner tympan: then while one pressman is beating the letter with the balls *g*, covered with ink taken from the ink-block, the other person places a sheet of white paper on the tympan-sheet; turns down the frisket upon it, to keep the paper clean and prevent its slipping; then bringing the tympan upon the form, and turning the rounce, he brings the form with the stone, &c. weighing about 300 lbs. weight, under the platten; pulls with the bar, by which means the platten presses the blankets and paper close upon the letter, whereby half the form is printed; then easing the bar, he draws the form still forward; gives a second pull; and letting go the bar, turns back the form, takes up the tympan and frisket, takes out the printed sheet, and lays on a fresh one; and this is repeated till he has taken off the impression upon the full number of sheets the edition is to consist of. One side of the sheet being thus printed, the form for the other is laid upon the press, and worked off in the same manner.

To the above description of the printing press, we shall add that of one invented by Mr. Nicholson, and for which a patent was granted in 1790. This machine is recommended by the inventor as being superior to other printing presses in cheapness, accuracy, and neatness, and is adapted with some slight variations in its construction for printing on paper, linen, cotton, and woollen. Three particulars are to be attended to in the invention.

1st, The manner of preparing and placing the types, engravings, or carvings, from which the impression is to be made; 2dly, In applying the ink or colouring matter to types or engravings; and 3dly, In taking off the impression.

1st, The moulds, punches, and matrices, for casting letters, are made in the same manner, and with the same materials, as other letter-founders do, excepting that instead of leaving a space in the mould for the stem of one letter only, he leaves spaces for two, three, or more letters, to be cast at one pouring of the metal; and at the lower extremity of each of those spaces (which communicate by a common groove at top) he places a matrix, or piece of copper, with the letter punched upon its face in the usual way. And moreover, he brings the stem of his letters to a due form and finish, not only by rubbing it upon a stone, and scraping it when arranged in the finishing-stick, but likewise by scraping it, on one or more sides, in a finishing-stick, whose hollowed part is less deep at the inner than the outer side. He calls that side of the groove which is nearest the face of the disposed letter, the outer side; and the purpose accomplished by this method of scraping is, that of rendering the tail of the letter gradually

smaller the more remote it is, or farther from the face. Such letters may be firmly imposed upon a cylindrical surface, in the same manner as common letters are imposed upon a flat stone.

2dly, The ink or colouring matter is applied to the types, forms, or plates, by causing the surface of a cylinder, smeared or wetted with the colouring matter, to roll over the surfaces of the said forms or plates, or by causing the forms or plates to apply themselves successively to the surface of the cylinder. The surface of this colouring cylinder is covered with leather, or with woollen, linen, or cotton-cloth. When the colour to be used is thin, as in calico-printing, and in almost every case, the covering is supported by a firm elastic stuffing, consisting of hair, or wool, or woollen cloth wrapped one or more folds round the cylinder. When the covering consists of woollen cloth, the stuffing must be defended by leather, or oilskin, to prevent its imbibing too much colour, and by that means losing its elasticity. It is absolutely necessary that the colouring matter be evenly distributed over the surface of the cylinder; and for this purpose, when the colour is thick and stiff, as in letter-press printing, he applies two, three, or more small cylinders, called distributing-rollers, longitudinally against the colouring cylinders, so that they may be turned by the motion of the latter; and the effect of this application is, that every lump or mass of colour which may be redundant, or irregularly placed upon the face of the colouring cylinder, will be pressed, spread, and partly taken up, and carried by the small rollers to the other parts of the colouring cylinder; so that this last will very speedily acquire and preserve an even face of colour. But if the colouring matter be thinner, he does not apply more than one or two of these distributing rollers; and, if it be very thin, he applies an even blunt edge of metal, or wood, or a straight brush, or both of these last, against the colouring cylinder, for the purpose of rendering its colour uniform. When he applies colour to an engraved plate, or cylinder, or through the interstices of a perforated pattern, as in the manufacturing some kinds of paper-hangings, he uses a cylinder entirely covered with hair or bristles in the manner of a brush.

3dly, The impressions, even in letter-press printing, are performed by the action of a cylinder or cylindrical surface. The following is the construction of this machine. Fig. 3. represents a printing-press, more especially applicable to the printing of books. A and E are two cylinders, running or turning in a strong frame of wood, or metal, or both. The cylinder A is faced with woollen cloth, and is capable of being pressed with more or less force upon HI, by means of the lever M. HI is a long table, which is capable of moving endwise, backwards and forwards, upon the rollers E and K. The roller A acts upon this table by means of a cog-wheel, or by straps, so as to draw it backwards and forwards by the motion of its handle L. The table is kept in the same line by grooves on its sides, which contain the cylinder A. D is a chase, containing letter set up and imposed. B is a box, containing a colouring-roller, with its distributing-rollers CC; it is supported by the arm N. O is a cylinder faced with leather, and lying across an ink-block; this cylinder is fixed by the middle to a bended lever moveable on the joint Q.

The action. When D, or the letter, is drawn beneath the cylinder B, it receives ink; and when it has passed into the position R, a workman

# PRINTING.

places or turns down a tympan with paper upon it (this tympan differs in no respect from the usual one, except that its hinge opens sidewise); it then proceeds to pass under the cylinder A, which presses it successively through its whole surface. On the other side, at S, the workman takes off the paper, and leaves the tympan up. This motion causes the cylinder B to revolve continually, and consequently to render its inked surface very uniform, by the action of its distributing-rollers CC; and, when the table has passed to its extreme distance in the direction now spoken of, the arm G touches the lever P, and raises the cylinder O off the ink-block, by which means it dabs against one of the distributing rollers, and gives it a small quantity of ink. The returning motion of the table carries the letter again under the roller B, which again inks it, and the process of printing another sheet goes on as before.

Fig. 4. is another printing press. In this, B is the inking-roller; A is a cylinder, having the letter imposed upon its surface; and E is a cylinder, having its uniform surface covered with woollen cloth: these three cylinders are connected, either by cogs or straps at the edges of each. The machine is uniformly turned in one direction by the handle L. The workman applies a sheet of paper to the surface of E, where it is retained, either by points in the usual manner, or by the apparatus to be described in treating of fig. 4. The paper passes between E and A, and receives an impression; after which the workman takes it off, and applies another sheet; and in the mean time the letter on the surface of A passes round against the surface of B, and receives ink during the rotation of B. The distributing-rollers CC, do their office as in the machine fig. 1.; and once in every revolution the tail F, affixed to B, raises the inking-piece G, so as to cause it to touch one of the distributing-rollers, and supply it with ink. In this way therefore the repeated printing of sheet after sheet goes on.

Fig. 5. is a printing press more particularly adapted to print cottons, silks, paper-hangings, or other articles which run of a considerable length. A is a cylinder covered with woollen cloth, or other soft substance. The web or piece of cotton, or other goods, is passed round this cylinder, from the carrying-roller F to the receiving-rollers GH; which are connected by a piece of linen, woollen, or hair-cloth, in the manner of a jack-towel, sewed round them; the rotation of this towel carries away the printed stuff or goods, and deposits them at L. KL is a moveable box, containing three rollers, which move against each other in rotation. The lowest roller C revolves in a mass of colour, contained in a trough or vessel in the bottom part of the box KL; the surface of this colour is represented by the line MN. The next roller B is stuffed and covered as described in section 2. The pressure of B against C prevents the cylinder B from receiving too much colour. D is a cut or carved cylinder, which receives colour, during the rotation, from the roller B, and impresses it upon the web as it passes round the cylinder A; in this way the constant and effectual action of the machine is sufficiently obvious. It must be observed, that the cylinders ADB and G are connected together by cog-wheels, straps, or other well-known equivalent contrivances; so that the handle P drives the whole, without their necessarily depending on any adhesion or friction at their surfaces. The pressure of B against D is governed by an adjustment of the axis of D, whose

sockets are capable of a small motion; and the pressure of D against A is governed by the position of the whole box KL. When it is required to print more than one colour upon the same piece, it must pass two or more times through the machine; or, in those cases where the materials are liable to change their dimensions, it is necessary to apply, at one and the same time, two or more such boxes as KL, with their respective cylinders, so that the pattern cylinder of each may make its impression upon the web or material to be printed on.

Fig. 6. is a printing-press, chiefly of use for books and papers. 1, 2, 3, 4, represent a long table with ledgers on each side; so that the two cylinders A and B can run backwards and forwards without any side shake. In one of these ledges is placed a strip or plate of metal cut into teeth, which lock into corresponding teeth in each cylinder; by which means the two cylinders roll along, without the possibility of changing the relative positions of their surfaces at any determinate part of the table. This may also be effected by straps, and may indeed be accomplished, with tolerable accuracy, by the mere rolling of the cylinders on the smooth or flat ledges without any provision. A is the printing-cylinder, covered with woollen cloth, and B is the inking-cylinder, with its distributing-rollers. The table may be divided into four compartments, marked with a thicker bounding line than the rest, and numbered 1, 2, 3, 4. At 1 is placed a sheet of paper; at 2 is the form or chase, containing letter set and imposed; at 3 is an apparatus for receiving the printed sheet; and 4 is employed in no other use than as a place of standing for the carriage E, after it has passed through one operation, and when it takes ink at F. Its action is as follows: the carriage is thrust forward by the workman, and as the roller A passes over the space numbered 1, it takes up the sheet of paper previously laid there, while the roller B runs over the form and inks the letter. The sheet of paper being wrapped round the cylinder A, is pressed against the form as that cylinder proceeds, and consequently it receives an impression. When A arrives at the space numbered 3, it lets go the sheet of paper, while the prominent part of the carriage G strikes the lever P, and raises the inking-piece, which applies itself against one of the distributing rollers. In this manner therefore the cylinder A returns empty, and the cylinder B inked, and in the mean time the workman places another sheet of paper ready in the space numbered 1. Thus it is that the operation proceeds in the printing of one sheet after another.

The preceding description is not encumbered with an account of the apparatus by which the paper is taken up and laid down. This may be done in several ways: Figs. 11. and 12. represent one of the methods. DE is a lever, moving on the centre pin C, and having its end D pressed upwards by the action of the spring G. The shoulder which contains the pin C is fixed in another piece F, which is inserted in a groove in the surface of the cylinder A (fig. 6.), so that it is capable of moving in and out, in a direction parallel to the axis of that cylinder. As that cylinder proceeds, it meets a pin in the table; which (letter P, fig. 11.) acting on the inclined plane at the other end of the lever, throws the whole inwards, in the position represented in fig. 12.; in which case the extremity D shoots inwards, and applies itself against the side of the cylinder.

In fig. 13. is a representation of part of the

## PRINTING.

table; the dotted square represents a sheet of paper, and the four small shaped squares denote holes in the board, with pins standing beside them. When the lever DE (fig. 12.) shoots forward, it is situated in one of these holes, and advances under the edge of the paper, which consequently it presses and retains against the cylinder with its extremity D. Nothing more remains to be said respecting the taking up, but that the cylinder is provided with two pair of these clasps or levers, which are so fixed as to correspond with four holes represented in fig. 13. It will be easy to understand how the paper is deposited in the compartment N° 3. (fig. 6.). A pin P (fig. 12.) rising out of the platform or table, acts against a pin E, projecting sidewise out of the lever, and must of course draw the slider and its lever to the original position; the paper consequently will be let go, and its disengagement is rendered certain by an apparatus fixed in the compartment numbered 3. (fig. 6.) of exactly the same kind as that upon the cylinder, and which, by the action of a pin duly placed in the surface of the cylinder A, takes the paper from the cylinder in precisely the same manner as that cylinder originally took it up in the compartment numbered 1 (fig. 6.).

Figs. 7, 8, and 9, represent a simpler apparatus for accomplishing the same purpose. If, A a B b (fig. 9.) be supposed to represent a thick plate of metal of a circular form, with two pins, A and B, proceeding sidewise or perpendicularly out of its plane, and diametrically opposite to each other, and G another pin proceeding in the direction of that plane, then it is obvious that any force applied to the pin A so as to press it into the position *a* (by turning the plate on its axis or centre X), will at the same time cause the pin G to acquire the position *g*; and, on the other hand, when B is at *b*, or the dotted representation of the side pin, if any pressure be applied to restore its original position at B, the pin *g* will return back to G. Now the figures 7 and 8 exhibit an apparatus of this kind, applied to the cylinder A; and that cylinder, by rolling over the pins P and *p*, properly fixed in the table to re-act upon the apparatus, will cause its prominent part G either to apply to the cylinder and clasp the paper, or to rise up and let it go. The compartment numbered 3 (fig. 6.) must of course have an apparatus of the same kind to be acted upon by pins from A, in order that it may take the paper from that cylinder.

There is one other circumstance belonging to this machine which remains to be explained. When the carriage E (fig. 6.) goes out in the direction of the numbers 1, 2, 3, 4, both rollers, A and B, press the form of letter in their passage; but in their return back again the roller A, having no paper upon it, would itself become soiled, by taking a faint impression from the letter, if it were not prevented from touching it: the manner of effecting this may be understood from fig. 14. The apparatus there represented is fixed upon the outside of the carriage E, near the lower corner, in the vicinity of the roller A; the whole of this projects sidewise beyond the ledge of the table, except the small truck or wheel B. The irregularly-triangular piece, which is shaded by the stroke of the pen, carries this wheel, and also a catch moveable on the axis or pin E. The whole piece is moveable on the pin A which connects it to the carriage. CD, or the part which is shaded by dotting, is a detent, which serves to hold the piece down in a certain position. It may be observed, that both

the detent and the triangular piece are furnished each with a claw, which holds in one direction, but trips or yields in the other, like the jacks of a harpsichord, or resembling certain pieces used in clock and watch making, as is clearly represented in the figure. These claws overhang the side of the table, and their effect is as follows: There is a pin C (fig. 6.) between the compartments of the table numbered 2 and 3, but which is marked F in fig. 14. where GH represents the table. In the outward run of the carriage these claws strike that pin, but with no other effect than that they yield for an instant, and as instantly resume their original position by the action of their respective slender back-springs. When the carriage returns, the claw of the detent indeed strikes the pin, but with as little effect as before, because its derangement is instantly removed by the action of the back spring of the detent itself; but, when the claw of the triangular piece takes the pin, the whole piece is made to revolve on its axis or pin A, the wheel B is forced down, so as to lift that end of the carriage, and the detent, catching on the piece at C, prevents the former position from being recovered. The consequence of this is, that the carriage runs upon the truck B (and its correspondent truck on the opposite side) instead of the cylinder A, which is too much raised to take the letter, and soil itself; but as soon as the end of the carriage has passed clear of the letter, another pin R (fig. 6.) takes the claw of the detent, and draws it off the triangular piece; at which instant the cylinder A subsides to its usual place and performs its functions as before. This last pin R does not affect the claw of the triangular piece, because it is placed too low; and the claw of the detent is made the longest, on purpose that it may strike this pin.

Fig. 10. represents an instrument for printing floor-cloths, paper-hangings and the like, with stiff paint and a brush. D is a copper or metallic cylinder fixed in a frame A, like a garden-roller; its carved part is thin, and is cut through in various places, according to the desired pattern. A strong axis passes through the cylinder, and its extremities are firmly attached to the frame A. To this axis is fixed a vessel or box of the same kind, and answering the same purpose as the box KL in fig. 5. It carries a cylinder P, which revolves in the colour; another cylinder E, which revolves in contact with P: and a third cylinder B, whose exterior surface is covered with hair, after the manner of a brush, and revolves in contact with E. This cylinder B is adjusted by its axis in such a manner that its brush-part sweeps in the perforated parts of the metallic cylinder D. The circle C represents a cog-wheel fixed concentric to the cylinder D, and revolving with it; this wheel takes another wheel concentric to, and fixed to, B; hence the action is as follows: When the metallic cylinder is wheeled or rolled along any surface, its cog-wheel C drives the brush B in the contrary direction; and this brush cylinder being connected by cogs or otherwise with E and P, causes those also to revolve and supply it with colour. As the successive openings of the cylinder D, therefore, come in contact with the ground, the several parts of the brush will traverse the uncovered part of that ground, and paint the pattern upon it. The wheel G, being kept lightly on the ground, serves to determine the line of contact, that it shall be the part opposite to B, and no other.

It has always been justly reckoned a desirable

# PRINTING.

object to obtain an accession of power in the printing press, and at the same time a diminution of labour, and an equable application of force. This is in great measure accomplished by the press invented by earl Stanhope, and of which we have given an elevation in the upper part of pl. 145. In the common press, the perfect plane in the table and platten has long been a desideratum, which in the Stanhope press is completely supplied. Here the cheeks, the cap, and the winter, of the old press, are not required. In this press the platten is fixed to the hose, or apparatus, through which the screw works: and it is suspended to the short arm by a lever, provided with a counterbalancing weight, by which the form is released from the platten, at the return of the bar after the pull. For the stone is substituted a cast iron block which has its upper surface made accurately flat, and is laid correctly horizontal; this, with the provision made for a vertical pressure on the platten, and the care taken to set its lower face parallel to the surface of the block, ensures a uniform pressure on the form. For a minute description of this ingenious press, illustrated by drawings of the minutest parts, we beg to refer the reader to Mr. Stower's interesting work, the *Printer's Grammar*, where also may be seen a perspicuous account of another printing press, invented by Mr. Brooke.

**PRINTING PRESS for copper plate printing**, or, as it is usually termed, for *rolling press printing*, is employed in taking off prints or impressions from copperplates engraved, etched, or scraped, as in mezzotintos. See **ENGRAVING**.

This art is said to have been as ancient as the year 1540, and to owe its origin to Finiguerra, a Florentine goldsmith, who pouring some melted brimstone on an engraved plate, found the exact impression of the engraving left in the cold brimstone, marked with black taken out of the strokes by the liquid sulphur: upon this, he attempted to do the same on silver plates with wet paper, by rolling it smoothly with a roller; and this succeeded; but this art was not used in England till the reign of king James I. when it was brought from Antwerp by Speld. The form of the rolling-press, the composition of the ink used therein, and the manner of applying both in taking off prints, are as follows:

The rolling-press AL, fig. 15. pl. 144. may be divided into two parts, the body and carriage: the body consists of two wooden cheeks PP, placed perpendicularly on a stand or foot LM, which sustains the whole press. From the foot likewise are four other perpendicular pieces, *c, c, c, c*, joined by other cross or horizontal ones, *d, d, d*, which serve to sustain a smooth even plank or table HK, about four feet and a half long, two feet and a half broad, and an inch and a half thick. Into the cheeks go two wooden cylinders or rollers, DE, FG, about six inches in diameter, borne up at each end by the cheeks, whose ends, which are lessened to about two inches diameter, and called trunnions, turn in the cheeks about two pieces of wood in form of half-moons, lined with polished iron to facilitate the motion. Lastly, to one of the trunnions of the upper roller is fastened a cross, consisting of two levers AB, or pieces of wood, traversing each other, the arms of which cross serve instead of the bar or handle of the letter-press, by turning the upper roller, and when the plank is between the two rollers, giving the same motion to the under one, by drawing the plank forward and backward.

The ink used for copperplates is a composition made of the stones of peaches and apricots, the bones of sheep and ivory, all well burnt, and called Frankfort black, mixed with nut-oil that has been well boiled, and ground together on a marble, after the same manner as painters do their colours.

The method of printing from copperplates is as follows: They take a small quantity of this ink on a rubber made of linen-rags, strongly bound about each other, and therewith smear the whole face of the plate as it lies on a grate over a charcoal fire. The plate being sufficiently inked, they first wipe it over with a foul rag, then with the palm of their left hand, and then with that of the right; and to dry the hand and forward the wiping, they rub it from time to time in whitening. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, the address of the workman consists. The plate thus prepared, is laid on the plank of the press; over the plate is laid the paper, first well moistened, to receive the impression; and over the paper two or three folds of flannel. Things thus disposed, the arms of the cross are pulled, and by that means the plate with its furniture passed through between the rollers, which pinching very strongly, yet equally, press the moistened paper into the strokes of the engraving, whence it licks out the ink.

**PRINTING MACHINE for numbering bank notes.** This is a most ingenious invention of Mr. Bramah's, recently adopted by the bank of England, for filling up the dates and numbers of their notes; which when printed from the copperplates have blanks left for the dates and numbers. These were formerly inserted in writing, for each note being different, in these particulars, did not admit of being printed, until Mr. Bramah produced his machine, which is a small printing press, provided with such mechanism as to change its types every time after an impression has been taken. Thus after having printed the note No. 1. it will at the next impression which is made have its type changed to No. 2, and so on.

Plate 143. contains a drawing of this machine; fig. 1. shewing it in perspective, as it appears with a bank note in it, prepared for having the numbers printed thereon. The note is placed against a flat tablet of brass, AA, its situation being determined by two fine pins fixed in the table, which are made to penetrate the paper at two small dots, printed upon it by the copper plate which printed the words of the note, as shown in the drawing; and it is confined in its position against the tablet by a piece of vellum B, stretched in a brass frame, connected by hinges *a a* to the tablet AA on which it folds down, enclosing the note as it were in a book: the vellum has openings cut through it, at the places where the machine is to print upon the note. These are, the number twice repeated, which is to be printed first in large characters over the words of the first line *I promise*, and again over the words *or bearer*, at the end of the first line; as for instance

N<sup>o</sup> 70486

N<sup>o</sup> 70480

1812 Jan<sup>y</sup>. 10. London 10 Jan<sup>y</sup>. 1812

The types for printing these words are fixed so as to project a little above the surface of a flat brass plate DD, forming the lid of an iron box

FFG, containing the mechanism; by which the types for the figures are shifted every time after an impression has been taken from them; which is done by bringing the flat table A having the note attached to it, down upon the types (previously inked) by the handle H, which, as well as the tablet, moves on an axis II, supported in two ears projecting from the sides of the iron box. The tablet is attached to this axis by means of screws (as shewn in fig. 3.), which admit of adjusting it in any direction so that it will fall perfectly flat upon the type, and print with equal pressure in all parts of the note. An impression being thus taken, on lifting up the handle H to take out the note, the types of the number are shifted by the mechanism in order to print the succeeding number. To explain the manner of effecting this we must refer to fig. 2, which is a plan of the wheelwork contained in the box detached from the frame. Here LL are two clusters of brass circles, consisting of 5 in each, placed close together, and connected by a strong spindle M passing through the centres of them all, and upon which they all revolve freely. Each circle, as shewn in fig. 3. has its circumference divided into 11 cogs, and in each cog a space is cut to receive a type *n n*, which are arranged round the cogs in a series of 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, and a blank; and as the circles turn round independent of each other, any combination of figures may be made by them, which is less than No. 99,999, beyond which number the bank notes have not extended. The circles are turned round on their central axis by means of wheels OP fixed on an axis Q Q, extending across the frame of the machine. These wheels have 11 teeth, which operate between the teeth of the circle L as shewn in fig. 3 to turn them round, but without touching the types. The axis Q receives its motion by means of a wheel R, similar to O and P, fixed upon the middle of it, which is acted upon by a detent I, fig. 3. moving with the axis I, which every time the handle is raised up into the position of the view fig. 1, intercepts a tooth of the wheel R and moves it forwards. This by the same movement advances the circles L one tooth, and brings up a succeeding type through the aperture in the brass plate D. The wheels upon the axis Q are so narrow upon the edge as to engage only one of the circles L at the same time, and are at such a distance asunder upon their axis as to engage the same circle of each cluster at one time: the axis can be shifted endways in its bearings to operate with any one of the five circles in each cluster, and can be retained, in any position, by a semicircular clip, which enters into circular grooves formed round the spindle, of which there are 5 (as W, fig. 1.), one corresponding with each of the circles. The shifting is performed by a knob at the end of the spindle, as shewn at Q, fig. 1.

The circles have all a tendency to assume the position in which the types are proper for printing, that is, with their upper surface parallel to the brass plate D, by means of a small pin fitted into the axis M, and having a constant pressure outwards by a spiral spring. This pin comes to rest in an angular notch, made within side the circle opposite each type, as shown by the dark shaded parts in fig. 3; and each circle is provided with one.

The machine is used in this manner: suppose the circles turned round to set their types so that all the blanks are upwards, except the first circle at the right hand side of each cluster. These present the figure 1: the type for No. and the date, being

cast in stereotype, are pinned down upon the brass plate D at c, c, and the date piece is changed every day. The spindle of Q is set for its wheels to work in the teeth of these right hand circles. A note is now put on the tablet, the types inked with a printer's ball, and an impression taken; in lifting up the handle, the detent I at the back of its axis seizes a tooth of the wheel R, and by turning it round advances the two right hand circles of each cluster, so as to bring up No. 2. Another note is now printed, then No. 3 and so on, till No. 9 is printed, and 0 brought up, after which the handle is brought down twice, without printing any note. This brings up the blank space and No. 1. The axis is now shifted by its knob Q, fig. 1. to act upon the second circle from the right hand, and one motion of the handle being made brings up 0 of the second circle, making 01 <sup>N</sup> which when printed (types being always in reverse) will be No. 10. The first circle which before was units is now become tens, and the second units, which shifts at every impression to 11, 12, &c. up to 19, and after printing this the 0 comes up, making 10. The first circle is then pushed forwards by the printer with a small wooden skewer, and 2 in the first circle brought up, making 20. In this manner it proceeds to 99, the machine altering itself at every unit, but requires to be set by hand to advance for every ten. When 100 is to be printed, the axis is shifted to the 3d circle which becomes units, the 2d tens, and the first hundreds. The printing then proceeds as before, the units being advanced by the machine, but the tens and hundreds as often as they require it being advanced by hand. At 1000 the axis is shifted to the 4th circle, and the denomination of each is changed by this becoming the unit; 3 circles must now be moved by hand. On arriving at 10,000 the 5th circle must be made unit by shifting the axis to it, and the 4 first are moved when necessary by hand: and in this manner the machine will print up to 99,999, which is 100,000 wanting 1.

The machines in actual use at the bank of England, which are 40 in number, differ from our drawing in having two systems of circles, and a tablet of double length, for printing two notes at the same time; because the copper plates are of double size, and print two notes at once on the same paper, which is afterwards cut in two.

By these machines the labour of filling up the notes is reduced to less than  $\frac{1}{4}$  of what it was before their introduction, when one clerk was expected to fill up in writing 400 notes per day, whereas by one of the machines he can print 1300 double notes, which is equal to 2600 single ones.

**P. MEDII.** (*Musculus prior medii.*) An extensor interosseus muscle of the hand. See **INTEROSSEI MANUS.**

**PRIOR** (Matthew), an elegant and celebrated English poet, was the son of Mr. George Prior, a citizen and joiner of London, where he was born in 1664. His father dying while he was young, he was left to the care of his uncle, a vintner, who behaved to him with the tenderness of a parent. He had him educated at Westminster-school, after which he took him home, intending to bring him up to his own business. But he still prosecuted the study of the classics at his leisure hours, and particularly his favourite, Horace; by which means he was soon taken notice of by the polite company who resorted to his uncle's house. One day, as the earl of Dorset, with several other persons of rank, were at this tavern, the discourse turned upon the Odes of Horace, and the company being divided in their opinions about a passage in that poet, one of the gentlemen said, "We are not like to agree in our criticisms, but if I am not mistaken, there is a young fellow in the house who is able to set us all right:" upon which he named Mr. Prior, who was immediately sent for, and desired to give his opinion of Horace's meaning in the ode under debate. This he did with great modesty, and so much to the satisfaction of the company, that the earl of Dorset determined to remove him to a more agreeable station; and accordingly had him sent to St. John's college in Cambridge, where he at length became fellow of that college. He there contracted an intimate friendship with Charles Montague, afterwards earl of Halifax, in conjunction with whom he wrote a very humorous piece, intitled the Hind and the Panther transversed to the story of the Country Mouse and City Mouse, in answer to Mr. Dryden's poem called the Hind and Panther. Upon the revolution, Mr. Prior was brought to court by the earl of Dorset, and in 1690 was made secretary to the earl of Berkeley, plenipotentiary for king William and queen Mary, at the congress at the Hague; and afterwards appointed secretary to the earls of Pembroke and Jersey, and sir William Williamson, ambassadors and plenipotentiaries at the treaty of Ryswick in 1697; as he was likewise in 1698 to the earl of Portland, ambassador to the court of France. While he was in that kingdom, one of the officers of the French king's household, shewing him the royal apartments at Versailles, and particularly the paintings of Le Brun, in which are represented the victories of Lewis XIV. asked him whether king William's actions were also to be seen in his palace? "No, Sir," answered Mr. Prior, "the monuments of my master's actions are to be seen every where but in his own house." In 1697 he was made secretary of state for Ireland, and in 1700 was ap-

pointed one of the lords commissioners of trade and plantations, and was chosen member of parliament for East Grinstead in Sussex. In 1711 he was made one of the commissioners of customs, and sent minister plenipotentiary into France, for negotiating a peace with that kingdom: but the year after Geo. I. came to the throne he was recalled from France, and upon his arrival was taken up by a warrant from the house of commons, and soon after strictly examined by a committee of the privy-council. Robert Walpole, esq. then moved the house of commons for an impeachment against him, and he was ordered into custody: but though he was one of the persons excepted out of the act of grace which passed in 1717, he was at the close of that year discharged from his confinement; upon which he spent the remainder of his days in tranquillity and retirement, chiefly at his estate at Downhall in Essex. He died at the earl of Oxford's seat at Wimpole in Cambridgeshire, the 18th of September, 1721, and was interred in Westminster abbey, where a monument is erected to his memory. The following is the epitaph he wrote for himself:

"Nobles and heralds, by your leave,  
Here lie the bones of Matthew Prior,  
The son of Adam and of Eve:  
Let Bourbon or Nassau go higher."

**PRIORIES** (Alien), were cells of religious houses in England which belonged to foreign monasteries: for when manors or tithes were given to foreign convents, the monks, either to increase their own rule, or rather to have faithful stewards of their revenues, built a small convent here for the reception of such a number as they thought proper, and constituted priors over them. Within these cells there was the same distinction as in those priories which were cells subordinate to some great abbey; some of these were conventual, and, having priors of their own choosing, thereby became entire societies within themselves, and received the revenues belonging to their several houses for their own use and benefit, paying only the ancient apport, acknowledgment, or obvention, at first the surpluseage, to the foreign house; but others depended entirely on the foreign houses, who appointed and removed their priors at pleasure. These transmitted all their revenues to the foreign head houses; for which reason their estates were generally seized to carry on the wars between England and France, and restored to them again on return of peace. These alien priories were most of them founded by such as had foreign abbeys founded by themselves or by some of their family.

The whole number is not exactly ascertained; the Monasticon has given a list of 100: Weever, p. 338, says 110.

They were all dissolved by act of parliament 2 Henry V. and all their estates vested in the crown, except some lands granted to the college of Fotheringhay. The act of dissolution is not printed in the statute books, but it is to

be found entire in Rymer's *Fœdera*, ix. 283. and in the *Parliament Rolls*, vol. iv. p. 22. In general, these lands were appropriated to religious uses. Henry VI. endowed his foundations at Eton and Cambridge with the lands of the alien priories, in pursuance of his father's design to appropriate them all to a noble college at Oxford. Others were granted in fee to the prelates, nobility, or private persons. Such as remained in the crown were granted by Henry VI. 1440, to archbishop Chicheley, &c. and they became part of his and the royal foundations.

**PRI/ORESS.** *s.* (from *prior*.) A lady superior of a convent of nuns.

**PRI/ORITY.** *s.* (from *prior*, adjective.) 1. The state of being first; precedence in time (*Hayward*). 2. Precedence in place (*Shak.*).

**PRI/ORSHIP.** *s.* (from *prior*.) The state or office of prior.

**PRI/ORY.** *s.* (from *prior*.) A covenant in dignity below an abbey (*Shakspeare*).

**PRISAGE.** *s.* (from *prise*.) A custom, now called butlerage, whereby the prince challenges out of every bark laden with wine, two tuns of wine at his price (*Cowell*).

**PRISCIANUS**, an eminent grammarian of Cæsarea, flourished at Constantinople about 525. Laurentius Valla calls Priscian, Donatus, and Servius, the "triumviri in grammatica;" and a person who writes false Latin is proverbially said "to break Priscian's head."

**PRISM**, in geometry, is a body, or solid, whose two ends are any plain figures which are parallel, equal, and similar; and its sides connecting those ends, are parallelograms. Hence, every section parallel to the ends, is the same kind of equal and similar figure as the ends themselves are; and the prism may be considered as generated by the parallel motion of this plane figure.

Prisms take their several particular names from the figure of their ends. Thus, when the end is a triangle, it is a triangular prism; when a square, a square prism; when a pentagon, a pentagonal prism; when a hexagon, a hexagonal prism; and so on. And hence the denomination prism comprises also the cube and parallelopipedon, the former being a square prism, and the latter a rectangular one. And even a cylinder may be considered as a round prism, or one that has an infinite number of sides. Also a prism is said to be regular or irregular according as the figure of its end is a regular or an irregular polygon.

The axis of a prism, is the line conceived to be drawn lengthways through the middle of it, connecting the centre of one end with that of the other end.

Prisms, again, are either right or oblique.

A right prism is that whose sides, and its axis, are perpendicular to its ends; like an upright tower. And

An oblique prism, is when the axis and sides are oblique to the ends; so that, when set upon one end, it inclines on one hand, like an inclined tower.

The principal properties of prisms are,

1. That all prisms are to one another in the ratio compounded of their bases and heights.

2. Similar prisms are to one another in the triplicate ratio of their like sides.

3. A prism is triple of a pyramid of equal base and height; and the solid content of a prism is found by multiplying the base by the perpendicular height.

4. The upright surface of a right prism is equal to a rectangle of the same height, and its breadth equal to the perimeter of the base or end. And therefore such upright surface of a right prism is found by multiplying the perimeter of the base by the perpendicular height. Also the upright surface of an oblique prism is found by computing those of all its parallelogram sides separately, and adding them together.

And if to the upright surface be added the areas of the two ends, the sum will be the whole surface of the prism.

**PRISM**, in dioptrics, is a piece of glass in form of a triangular prism: which is much used in experiments concerning the nature of light and colours. See **COLOUR**.

**PRISMATIC.** *a.* (*prismatique*, Fr. from *prism*.) Formed as a prism (*Pope*).

**PRISMATICALLY.** *ad.* (from *prismatic*.) In the form of a prism (*Boyle*).

**PRISMOID.** *s.* (*πρισμαειδης* and *ειδος*.) A body approaching to the form of a prism, having its ends parallel but unlike plane figures of the same number of sides.

**PRISON**, a gaol, or place of confinement. See **GAOL**. Lord Coke observes, that a prison is only a place of safe custody, *salva custodia*, not a place of punishment. Any place where a person is confined may be said to be a prison: and when a process is issued against one, he must, when arrested thereon, either be committed to prison, or be bound in a recognizance with sureties, or else give bail, according to the nature of the case, to appear at a certain day in court, there to make answer to what is alleged against him. When a person is taken and sent to prison in a civil case, he may be released by the plaintiff in the suit; but if it is for treason or felony, he may not regularly be discharged until he is indicted of the fact and acquitted.

The good policy of imprisonment for debt has been frequently called in question (probably by those who were most in danger of suffering from it). We are of opinion, however, that it is in the whole productive of salutary consequences in a state, and the terror of a gaol is in many cases an useful moral restraint. The following paper, however, set forth by the laudable society for the discharge and relief of persons imprisoned for small debts, will excite various reflections in different readers; and without any comment we submit it as a curious document to the statesman, or political arithmetician, as throwing some light on the manners and character of the age.

The following is a summary view of the money annually expended by the society for the

discharge and relief of persons imprisoned for small debts, Craven-street, Strand, from the institution in 1772, to the 31st of March 1804.

| 1772 No. of debtors discharged to and relieved. |                     | Expended. |       |
|-------------------------------------------------|---------------------|-----------|-------|
|                                                 |                     | £.        | s. d. |
| 1774                                            | 1772 for the sum of | 4622      | 17 1  |
| 1775                                            | 966                 | 1724      | 1 11  |
| 1776                                            | 673                 | 1842      | 13 3  |
| 1777                                            | 877                 | 1729      | 19 7  |
| 1778                                            | 779                 | 1764      | 0 11  |
| 1779                                            | 811                 | 1611      | 15 3  |
| 1780                                            | 628                 | 1288      | 17 1  |
| 1781                                            | 321                 | 828       | 15 9  |
| 1782                                            | 389                 | 935       | 3 9   |
| 1783                                            | 547                 | 1121      | 12 0  |
| 1784                                            | 535                 | 996       | 12 3  |
| 1785                                            | 463                 | 904       | 9 1   |
| 1786                                            | 339                 | 715       | 8 9   |
| 1787                                            | 343                 | 719       | 9 10  |
| 1788                                            | 710                 | 1566      | 4 2½  |
| 1789                                            | 612                 | 1926      | 3 3½  |
| 1790                                            | 798                 | 2303      | 9 3   |
| 1791                                            | 666                 | 1777      | 0 6   |
| 1792                                            | 460                 | 1297      | 14 7  |
| 1793                                            | 568                 | 1870      | 1 5   |
| 1794                                            | 540                 | 1844      | 14 9½ |
| 1795                                            | 434                 | 1438      | 6 1   |
| 1796                                            | 481                 | 1756      | 0 5   |
| 1797                                            | 490                 | 1606      | 15 0  |
| 1798                                            | 645                 | 2001      | 13 6  |
| 1799                                            | 578                 | 1553      | 14 5  |
| 1800                                            | 648                 | 2106      | 16 10 |
| 1801                                            | 1885                | 2870      | 4 4   |
| 1802                                            | 1125                | 2607      | 11 1  |
| 1803                                            | 927                 | 2892      | 14 0  |
| 1804                                            | 916                 | 2586      | 2 1   |

20,906 debtors, who had 69,115 persons immediately benefited for 547811. 3s. 5½d.

The average for the debts of the above 20,906 debtors is 2l. 12s. 4½d. each, and for each individual relieved 15s. 1d.

**TO PRISON.** *v. a.* (from the noun.) 1. To imprison; to shut up in hold; to restrain from liberty. 2. To captivate; to enchain (*Milton*). 3. To confine (*Shakspeare*).

**PRISONBASE.** *s.* A kind of rural play, commonly called *prisonbars* (*Sandys*).

**PRISONER.** *s.* (*prisonnier*, French.) 1. One who is confined in hold (*Bacon*). 2. A captive; one taken by the enemy (*Bacon*). 3. One under an arrest (*Dryden*).

**PRISONHOUSE.** *s.* Gaol; hold in which one is confined (*Shakspeare*).

**PRISONMENT.** *s.* (from *prison*.) Confinement; imprisonment; captivity (*Shaks.*).

**PRISRENDI**, a town of European Turkey, in Servia, and a bishop's see, with a magnificent church. It is seated on the Drin, 170 miles S. of Belgrade. Lon. 21. 3 E. Lat. 42. 20 N.

**PRISTINA**, a town of European Turkey, in Servia, which was pillaged by the Austrians in 1689. It is seated on the Rusca, 150 miles S. by E. of Belgrade. Lon. 21. 36 E. Lat. 42. 43 N.

VOL. LX.

**PRISTINE.** *a.* (*pristinus*, Lat.) First; ancient; original (*Phillips*).

**PRISTIS**, the name of one of the ships that engaged in the naval combat which was exhibited by Æneas at the anniversary of his father's death. She was commanded by Mnestheus.

**PRISTIS.** Saw-fish. In zoology, a genus of the class pisces, order chondroptergia. Snout long, flat, spinous down the edges; spiracles from four to five, lateral; body oblong, roundish, covered with a rough coriaceous skin; mouth beneath; nostrils before the mouth, half covered with a membranaceous flap; behind the eyes two oval orifices; ventral fins approximate; no anal fin. Five species, as follows.

1. *P. antiquorum*. Snout with from eighteen to twenty-four strong spines on each side; head flat on the fore-part; length of the snout five feet; teeth granulate; eyes large; iris golden; spiracles five; first dorsal fin opposite the ventral, second midway between the first and the tail; pectoral broad, long; caudal short. Inhabits the ocean; fifteen feet long; body above blackish, beneath whitish.

2. *P. pectinans*. Snout with from twenty-five to thirty-four narrower spines on each side. Inhabits the ocean; resembles the last, but the snout is narrower and slenderer; spines longer, slenderer.

3. *P. cuspidatus*. Snout with twenty-eight broad cuspidate spines on each side. The habitation of this is uncertain. A specimen of the snout was preserved in the Leverian Museum till its valuable articles were disposed of, the spines of which were as sharp at the point as a surgeon's lancet.

4. *P. microdon*. Spines on the snout small, hardly perforating the skin. Habitation, like that of the last, unknown; it is also described from a specimen in the Leverian Museum; twenty-eight inches long; snout ten inches; dorsal fins much hollowed out at the back-part.

5. *P. cirratus*. Snout cirrate in the middle; spines long, with intermediate shorter ones; the longer about twenty, sharp, and somewhat incurved; the shorter from three to six; about the middle of the snout on each side near the edge, a flexible appendage three inches and a half long, resembling the beards of the cod-fish; spiracles four; mouth with five rows of sharp minute teeth; tail lanceolate. Inhabits New Holland; about forty inches long; body pale-brown.

**PRITHEE.** A familiar corruption of *pray thee*, or *I pray thee* (*L'Estrange*).

**PRIVACY.** *s.* (from *private*.) 1. State of being secret; secrecy. 2. Retirement; retreat; place intended to be secret (*Dryden*). 3. (*privauté*, Fr.) Privity; joint knowledge; great familiarity. Improper use (*Arbuthnot*). 4. Taciturnity (*Ainsworth*).

**PRIVADO.** *s.* (Spanish.) A secret friend (*Bacon*).

**PRIVAS**, a town of France, capital of the department of Ardeche. It is seated on a hill,

near the confluence of three small rivers, 68 miles S. of Lyon. Lon. 4. 36 E. Lat. 44. 45 N.

**PRIVATE.** *a.* (*privatus*, Latin.) 1. Not open; secret (*Milton*). 2. Alone; not accompanied. 3. Being upon the same terms with the rest of the community; particular (*Hooker*). 4. Particular; not relating to the public (*Digby*). 5. *In PRIVATE*, Secretly; not publicly; not openly (*Granville*).

**PRIVATE.** *s.* A secret message (*Shakespeare*).

**PRIVATEERS**, are a kind of private men of war, the persons concerned wherein administer at their own costs a part of a war, by fitting out these ships of force, and providing them with all military stores; and they have, instead of pay, leave to keep what they take from the enemy, allowing the admiral his share, &c.

**TO PRIVATEER.** *v. a.* (from the noun.) To fit out ships against enemies, at the charge of private persons.

**PRIVATELY.** *ad.* (from *private*.) Secretly; not openly (*Shakespeare*).

**PRIVATENESS.** *s.* (from *private*.) 1. The state of a man in the same rank with the rest of the community. 2. Secrecy; privacy (*Bacon*). 3. Obscurity; retirement (*Watton*).

**PRIVATION.** *s.* (*privatio*, Latin.) 1. Removal or destruction of any thing or quality (*Davies*). 2. The act of the mind by which, in considering a subject, we separate it from any thing appendant. 3. The act of degrading from rank or office (*Bacon*).

**PRIVATIVE.** *a.* (*privativus*, Latin.) 1. Causing privation of any thing. 2. Consisting in the absence of something; not positive (*Taylor*).

**PRIVATIVE.** *s.* That of which the essence is the absence of something, as silence is only the absence of sound (*Bacon*).

**PRIVATIVE**, in grammar, a particle, which, prefixed to a word, changes it into a contrary sense.

Thus, among the Greeks, the *a* is used as a privative: as in *atheism*, atheist, acephalus, &c. The Latins have their privative in: as, *incomrigibilis*, *indeclinabilis*, &c. The English, French, &c. on occasion, borrow both the Latin and Greek privatives.

**PRIVATIVELY.** *ad.* (from *privative*.) 1. By the absence of something. 2. Negatively (*Hammond*).

**PRIVATIVENESS.** *s.* (from *privative*.) Notation of absence of something that should be present.

**PRIVET**, in botany. See **LIGUSTRUM**.

**PRIVET** (Mock). See **PHILLYREA**.

**PRIVILEGE.** *s.* (*privilege*, Fr. *privilegium*, Lat.) 1. Peculiar advantage (*Shakespeare*). 2. Immunity; right not universal (*Dryden*).

**PRIVILEGE**, in law, some peculiar benefit granted to certain persons or places, contrary to the usual course of the law.

Privileges are said to be personal or real. Personal privileges are such as are extended to peers, ambassadors, members of parliament

and of the convocation, and their mental servants, &c. A real privilege is that granted to some particular place; as the king's palace, the courts at Westminster, the universities, &c.

**TO PRIVILEGE.** *v. a.* (from the noun.) 1. To invest with rights or immunities; to grant a privilege (*Dryden*). 2. To exempt from censure or danger (*Sidney*). 3. To exempt from paying tax or impost (*Hale*).

**PRIVILY.** *ad.* (from *privy*.) Secretly; privately (*Spenser*).

**PRIVITY.** *s.* (*privauté*, Fr. from *privy*.) 1. Private communication (*Spenser*). 2. Consciousness; joint knowledge; private concurrence (*Hooker*). 3. (In the plural.) Secret parts (*Abbot*).

**PRIVY.** *a.* (*privé*, French.) 1. Private; not public; assigned to secret uses (*Shakespeare*). 2. Secret; clandestine (*Maccabees*). 3. Secret; not shown (*Ezekiel*). 4. Admitted to secrets of state (*Spectator*). 5. Conscious to any thing; admitted to participation of knowledge (*Daniel*).

**PRIVY.** *s.* Place of retirement; necessary house (*Swift*).

**PRIVY**, in law, denotes one who is partaker, or has an interest, in an affair.

**PRIVY COUNCIL**, is the principal council belonging to the king, and is generally called by way of eminence the council.

Privy counsellors are made by the king's nomination, without either patent or grant; and on taking the necessary oaths, they become immediately privy counsellors during the life of the king that chooses them, but subject to removal at his discretion. No inconvenience now arises from the extension of the number of the privy council, as those only attend who are especially summoned for that particular occasion.

The duty of a privy-counsellor appears from the oath of office, which consists of seven articles: 1. To advise the king according to the best of his cunning and discretion. 2. To advise for the king's honour and good of the public, without partiality, through affection, love, meed, doubt, or dread. 3. To keep the king's counsel secret. 4. To avoid corruption. 5. To help and strengthen the execution of what shall be there resolved. 6. To withstand all persons who would attempt the contrary. And, lastly, in general, 7. To observe, keep, and do all that a good and true counsellor ought to do to his sovereign lord.

The privy-council is the *primum mobile* of the state, and that which gives the motion and direction to all the inferior parts. It is likewise a court of justice of great antiquity; the primitive and ordinary way of government in England being by the king and privy-council. It has been frequently used by all our kings for determining controversies of great importance: the ordinary judges have sometimes declined giving judgment till they have consulted the king and privy-council; and the parliament have frequently referred matters of high moment to the same, as being by long experience better able

to judge of, and, by their secrecy and expedition, to transact some state affairs, than the lords and commons. At present, the privy-council takes cognizance of few or no matters except such as cannot well be determined by the known laws and ordinary courts; such as matters of complaint and sudden emergencies: their constant business being to consult for the public good in affairs of state. This power of the privy-council is to inquire into all offences against the government, and to commit the offenders to safe custody, in order to take their trial in some of the courts of law. But their jurisdiction herein is only to inquire, and not to punish; and the persons committed by them are entitled to their *habeas corpus* by statute 16 Car. I. cap. 10. as much as if committed by an ordinary justice of the peace.

The officers of the privy-council are four clerks of the council in ordinary, three clerks extraordinary, a keeper of the records, and two keepers of the council-chamber. See *PRESIDENT*.

*PRIVY-SEAL*, a seal which the king uses previously to such grants, &c. as are afterwards to pass the great seal. The privy seal is also sometimes used in matters of less consequence, which do not require the great seal.

*PRIZE*. *s.* (*priz*, Fr.) 1. A reward gained by contest with competitors (*Addison*). 2. Reward gained by any performance (*Dryden*). 3. (*prise*, Fr.) Something taken by adventure; plunder (*Pope*).

*PRIZE*, or *PRIZZ*, in maritime affairs, a vessel taken at sea from the enemies of a state, or from pirates; and that either by a man of war, a privateer, &c. having a commission for that purpose. Vessels are looked on as prize, if they fight under any other standard than that of the state from which they have their commission; if they have no charter-party, invoice, or bill of lading aboard; if loaded with effects belonging to the king's enemies, or with contraband goods. In ships of war the prizes are to be divided among the officers, seamen, &c. as his majesty shall appoint by proclamation; but among privateers, the division is according to the agreement between the owners. By stat. 13 Geo. II: c. 4. judges and officers failing of their duty in respect to the condemnation of prizes, forfeit 500*l.* with full costs of suit; one moiety to the king, and the other to the informer.

*To PRIZE*. *v. a.* (*priser*, French.) 1. To rate; to value at a certain price (*Shakspeare*). 2. To esteem; to value highly (*Dryden*).

*PRIZER*. *s.* (*priseur*, Fr.) He that values.

*PRIZEFIGHTER*. *s.* (*prize and fighter*.) One that fights publicly for a reward (*Brams*).

*PRO*. (Latin.) For; in defence of: *pro* and *con*, for *pro* and *contra*, for and against (*Prior*).

*PROA* (Flying), in navigation, is a name given to a vessel used in the South Seas, because with a brisk trade-wind it sails near twenty miles an hour. In the construction of the proa, the head and stern are exactly alike, but the sides are very different; the side intended to be always the lee-side being flat; and the

windward side made rounding, in the manner of other vessels; and to prevent her oversetting, which from her small breadth, and the straight run of her leeward side, would, without this precaution, infallibly happen, there is a frame laid out of her from windward, to the end of which is fastened a log fashioned in the shape of a small boat and made hollow. The weight of the frame is intended to balance the proa, and the small boat is by its buoyancy (as it is always in the water) to prevent her oversetting to windward.

*PROBABILITY* is a word of nearly the same import with likelihood. It denotes the appearance of truth, or that evidence arising from the preponderation of argument which produces opinion. (See *OPINION*.) Locke classes all arguments under the heads demonstrative and probable. Hume, with greater accuracy, divides them into demonstrations, proofs, and probabilities. Demonstration produces science; proof, belief; and probability, opinion.

Hardly any thing is susceptible of strict demonstration besides the mathematical sciences, and a few propositions in metaphysical theology. Physics rest upon principles capable, some of them, of complete proof by experience, and others of nothing more than probability by analogical reasoning. What has uniformly happened, we expect with the fullest confidence to happen again in similar circumstances; what has frequently happened, we likewise expect to happen again; but our expectation is not confident. Uniform experience is proof; frequent experience is probability.

Of probability there are degrees from then neighbourhood of certainty and demonstration, quite down to improbability and unlikeness, even to the confines of impossibility; and also degrees of assent, from certain knowledge, and, what is next to it, full assurance and confidence, quite down to conjecture, doubt, distrust, and disbelief. That proposition then is probable for which there are arguments, or proofs, to make it pass or be received for true. Probability being then to supply the defect of our knowledge, is always conversant about a thing whereof we have no certainty, but only some inducements to receive it for true. The grounds of it are, in short, these two following: First, the conformity of any thing with our own knowledge, experience, or observation. Secondly, the testimony of others vouching their observation and experience. In the testimony of others, is to be considered, 1. the number; 2. the integrity; 3. the skill of the witnesses; 4. the design of the author, if it be a testimony cited out of a book; 5. the consistency of the parts and circumstances of the relation; 6. contrary testimonies. The mind, before it rationally assents or dissents to any probable proposition, ought to examine all the grounds of probability, and see how they make more or less, for or against it; and, upon a due balancing the whole, reject or receive it, with a more or less firm assent, according to the preponderance of the greater grounds of probability, on one side, or the other.

**PROBABILITY OF AN EVENT**, in the doctrine of chances, is the ratio of the number of chances by which the event may happen, to the number by which it may both happen and fail. So that, if there be constituted a fraction, of which the numerator is the number of chances for the events happening, and the denominator the number for both happening and failing, that fraction will properly express the value of the probability of the event's happening. Thus, if an event have 3 chances for happening, and 2 for failing, the sum of which being 5, the fraction  $\frac{3}{5}$  will fitly represent the probability of its happening, and may be taken to be the measure of it. The same thing may be said of the probability of failing, which will likewise be measured by a fraction, whose numerator is the number of chances by which it may fail, and its denominator the whole number of chances both for its happening and failing: so the probability of the failing of the above event, which has 2 chances to fail, and 3 to happen, will be expressed or measured by the fraction  $\frac{2}{5}$ .

Hence, if there be added together the fractions which express the probability for both happening and failing, their sum will always be equal to unity, or 1; since the sum of their numerators will be equal to their common denominator. And since it is a certainty that an event will either happen or fail, it follows that a certainty, which may be considered as an infinitely great degree of probability, is fitly represented by unity. See CHANCES, LIFE, EXPECTATION.

**PROBABLE**. *a.* (*probable*, Fr. *probabilis*, Lat.) Likely; having more evidence than the contrary (*Hooker*).

**PROBABLY**. *ad.* (from *probable*.) Likely; in likelihood (*Swift*).

**PROBANG**. (from *probe*.) A long flexible piece of whalebone, having sponge fixed to the end. The use of it is, to force down into the stomach substances which happen to stick in the oesophagus.

**PROBATE OF WILLS**, is the exhibiting and proving wills and testaments before the ecclesiastical judges, delegated by the bishop, who is ordinary of the place where the party dies.

By the stamp acts, a very heavy duty is now payable upon these instruments, and a man can entitle himself to personal property only by means of a probate; that is, by having proved the will.

**PROBATION**. *s.* (*probatio*, from *probo*, Latin; *probation*, Fr.) 1. Proof; evidence; testimony (*Shakespeare*). 2. The act of proving by ratiocination or testimony (*Locke*). 3. Trial; examination (*Bacon*). 4. Moral trial (*Nelson*). 5. Trial before entrance into monastic life; noviciate (*Pope*).

**PROBATIONARY**. *a.* (from *probation*.) Serving for trial.

**PROBATIONER**. *s.* (from *probation*.) 1. One who is upon trial (*Dryden*). 2. A novice (*Decay of Piety*).

**PROBATIONERSHIP**. *s.* (from *proba-*

*tioner*.) State of being a probationer; noviciate (*Locke*).

**PROBATORY**. *a.* (from *probo*, Latin.) Serving for trial (*Bramhall*).

**PROBATUM EST**. A Latin expression added to the end of a receipt, signifying it is tried or proved (*Prior*).

**PROBE**. (*stylus*, from *probo*, to try; because surgeons try the depth and extent of wounds, &c. with it.) A chirurgical instrument of a long and slender form.

**PROBE-SCISSORS**. *s.* (*probe* and *scissors*.) Scissors used to open wounds, of which the blade thrust into the orifice has a button at the end (*Wiseman*).

**To PROBE**. *v. a.* (*probo*, Lat.) To search; to try by an instrument (*South*).

**PRO'BITY**. *s.* (*probité*, Fr. *probitas*, Lat.) Honesty; sincerity; veracity (*Fiddes*).

**PROBLEM**, (Πρόβλημα) in logic, a doubtful question, or a proposition that neither appears absolutely true nor false; and consequently may be asserted either in the affirmative or negative.

**PROBLEM**, in geometry, is a proposition wherein some operation or construction is required; as to divide a line or angle, erect or let fall perpendiculars, &c. See GEOMETRY.

**PROBLEM**, in algebra, is a question or proposition which requires some unknown truth to be investigated, and the truth of the discovery demonstrated.

**PROBLEM** (Kepler's), in astronomy. See KEPLER'S PROBLEM. See also the treatises on astronomy by Vince, Gregory, &c.

**PROBLEM** (Determinate, Diophantine, Indeterminate, Limited, Linear, Local, Plane, Solid, Sursolid, and Unlimited). See the additions.

**PROBLEM** (Deliacal), in geometry, is the doubling of a cube. This amounts to the same thing as the finding of two mean proportionals between two given lines; whence this also is called the deliacal problem. See DUPLICATION.

**PROBLEMATICAL**. *a.* (from *problem*; *problematique*, Fr.) Uncertain; unsettled; disputed; disputable (*Boyle*).

**PROBLEMATICALLY**. *ad.* Uncertainly.

**PROBOSCIS**, in natural history, is the trunk or snout of an elephant, and some other animals and insects. Flies, gnats, &c. are furnished with a proboscis or trunk, by means of which they suck the blood of animals, the juice of vegetables, &c. for their food.

**PROBUS**, M. Aurelius Severus, a native of Sirmium, in Pannonia. His father was originally a gardener, who, by entering the army, rose to the rank of a military tribune. His son obtained the same office in the 22d year of his age, and he distinguished himself so much by his virtues, that at the death of the emperor Tacitus, he was invested with the imperial purple. He conquered the enemies of Rome in Gaul and Germany. He defeated the Blemmyes in the neighbourhood of Egypt, with great slaughter, and his military character was

## PRO

so well established, that the king of Persia sued for peace by his ambassadors, and attempted to buy the conqueror's favours with the most splendid presents. Probus was then feasting upon the most common food when the ambassadors were introduced, but without even casting his eyes upon them, he said, that if their master did not give proper satisfaction to the Romans, he would lay his territories desolate, and as naked as the crown of his head. As he spoke, the emperor took off his cap, and shewed the baldness of his head to the ambassadors. His conditions were gladly accepted by the Persian monarch. Probus encouraged the liberal arts, and he himself repaired 70 cities in different parts of the empire, which had been reduced to ruins. His army, at length, mutinied, and he was murdered in the 50th year of his age, after a reign of six years and four months, before Christ 282. His very enemies deplored his fate, and even the army, which had been concerned in his fall, erected a monument over his body, and placed upon it this inscription: "Hic Probus imperator, vere probus situs est, victor omnium gentium barbararum, victor etiam tyrannorum."

**PROCA'CIOUS.** *a.* (*procaz*, Lat.) Petulant; loose.

**PROCA'CITY.** *s.* (from *procaxious*.) Petulance; sauciness.

**PROCATA'CTIC.** *a.* (*προκατακτικος*.) Fore-running; remotely antecedent (*Harvey*).

**PROCATA'RXIS.** *s.* (*προκαταρξις*.) The preexistent cause of a disease, which cooperates with others that are subsequent (*Quincy*).

**PROCEDENDO,** in law, a writ whereby a plea or cause, formerly called from an inferior court to the court of chancery, king's bench, or court of common pleas, by writ of privilege, habeas corpus, or certiorari, is released, and returned to the other court to be proceeded in, upon its appearing that the defendant has no cause of privilege, or that the matter in the party's allegation is not well proved.

**PROCEDURE.** *s.* (*procedure*, French.) 1. Manner of proceeding; management; conduct (*South*). 2. Act of proceeding; progress; process; operation (*Hale*). 3. Produce; thing produced (*Bacon*).

To **PROCEED.** *v.n.* (*procedo*, Lat.) 1. To pass from one thing or place to another (*Dryden*). 2. To go forward; to tend to the end designed; to advance (*Ben Jonson*). 3. To come forth from a place or from a sender (*John*). 4. To go or march in state (*Anon.*). 5. To issue; to arise; to be the effect of; to be produced from (*Shakspeare*). 6. To prosecute any design (*Locke*). 7. To be transacted; to be carried on (*Shakspeare*). 8. To make progress; to advance (*Milton*). 9. To carry on juridical process (*Clarendon*). 10. To transact; to act; to carry on any affair methodically (*Milton*). 11. To take effect; to have its course (*Ayliffe*). 12. To be propagated; to come by generation (*Milton*). 13. To be produced by the original efficient cause (*Milton*).

## PRO

**PROCEED.** *s.* Produce: as, the proceeds of an estate.

**PROCEEDER.** *s.* (from *proceed*.) One who goes forward; one who makes a progress (*Bacon*).

**PROCEEDING.** *s.* (*procedé*, French.) 1. Progress from one thing to another; series of conduct; transaction (*Swift*). 2. Legal procedure: as, such are the proceedings at law.

**PROCELEUSMATICUS,** in the ancient poetry, a foot consisting of four short syllables, or two pyrrhychiuses; as, *hominibus*.

**PROCELLARIA.** Petrel. In zoology, a genus of the class aves, order anseres. Bill toothless, a little compressed, hooked at the point; mandibles equal; nostrils cylindrical, tubular, truncate, lying in the base of the bill; feet palmate; the back toe pointing downwards, sessile, sharp, a mere spur. Twenty-four species, chiefly natives of America, and Australasia: two found in our own country. These live chiefly at sea, and except at breeding time are seldom seen near land; they have the faculty of spouting from their bills to a considerable distance a large quantity of pure oil; and feed on the fat of dead whales and fishes. The following are chiefly worthy of notice.

1. *P. pelagica*. Stormy procellaria. Black; rump white. Another variety with the head and sides bluish; scrag green; wing-coverts and rump spotted with green. The three outer tail feathers whitish at the base. Inhabits most seas; six inches long; except at breeding time is seldom seen near the shore; braves the utmost fury of storms, sometimes skimming with incredible velocity along the hollows of the waves, sometimes on the summits; if seen hovering round the sterns of vessels is a sure presage to seamen of foul weather.

2. *P. vittata*. Broad-billed petrel. Bluish-ash, beneath white; legs black; bill bluish-grey, very broad at the base. Inhabits the Antarctic seas; lays in holes on rocks; flies by night in numerous flocks; twelve inches long.

3. *P. urinatrix*. Diving petrel. Blackish-brown, beneath white; bill and chin black; legs blue-green, without the spur behind. Inhabits round New Zealand in numerous flocks; eight inches and a half long; dives dextrously.

4. *P. glacialis*. Fulmar petrel. Whitish; back hoary; bill and legs yellowish. Another variety with blackish wings; size of a gull, being seventeen inches long. These birds feed upon the blubber of whales, which is soon converted into an oil, which they inject into the mouths of their young. The natives of New Zealand are greatly indebted to the fulmars for almost every necessary of life. The flesh is a considerable part of their food; the plumage, down for their beds; and the oil, a provision for their lamps, and a medicine in almost every disorder.

5. *P. puffinus*. Shearwater petrel. Above black, beneath white; legs rufous. Another

variety, above cinereous, beneath white; tail clear white. Inhabit the Southern and Antarctic seas; fifteen inches long. They are also found at times in the Hebrides: they lay one egg, white, and blunt at each end; the young are taken in August, sated and barrelled; and when boiled eaten with potatoes. They feed their young with the oil discharged, as already mentioned, from their stomachs; and quit the Scottish isles towards the end of August or the beginning of September, apparently for the Mediterranean.

**PROCELLOUS.** *a.* (*procellosus*, Latin.) Tempestuous.

**PROCEPTION.** *s.* Preoccupation; act of taking something sooner than another: not in use (*King Charles*).

**PROCRITY.** *s.* (from *procerus*, Latin.) Tallness; height of stature (*Addison*).

**PROCESS.** *s.* (*processus*, Lat.) 1. Tendency; progressive course (*Hooker*). 2. Regular and gradual progress (*Knolles*). 3. Course; continual flux or passage (*Hale*). 4. Methodical management of any thing (*Prior*). 5. Course of law (*Suiff*).

**PROCESS.** (from *procedo*, to go before.) In anatomy, an eminence of a bone; as the spinous and transverse processes of the vertebræ.

**PROCESSUS CECIVERMIFORMIS.** In anatomy. See **INTESTINES**.

**PROCESSION.** *s.* (*processio*, Lat.) A train marching in ceremonious solemnity (*Hooker*).

**To PROCESSION.** *v. n.* (from the noun.) To go in procession. A low word.

**PROCESSIONAL.** *a.* (from *procession*.) Relating to procession.

**PROCESSIONARY.** *a.* (from *procession*.) Consisting in procession (*Hooker*).

**PRO'CHRONISM.** *s.* (προχρονισμ.) An error in chronology; a dating a thing before it happened.

**PROCIDO,** an island in the gulf of Naples, near that of Ischia, eight miles in circumference, and very fertile and populous. The capital, of the same name, is a small fortified place, on a high craggy rock, by the seaside. Lon. 14. 8 E. Lat. 40. 43 N.

**PRO'CIDENCE.** *s.* (*procidencia*, Lat.) Falling down; dependance below its natural place.

**PROCIDENTIA.** (from *procido*, to fall down.) In medicine, a falling down of any part of the body; thus, *procidencia ani*, uteri, vagina, &c.

**PRO'CINCT.** *s.* (*procinctus*, Lat.) Complete preparation; preparation brought to the point of action (*Milton*).

**PROCKIA**, in botany, a genus of the class polyandria, order monogynia. Calyx three-leaved, with sometimes two leaflets at the base; corolless; berry five-angled, many-seeded. Four species; one a shrub of Santa Cruz, the rest of the Mauritius.

**To PROCLAIM.** *v. a.* (*proclamo*, Latin.) 1. To promulgate or denounce by a solemn or legal publication (*Deuteronomy*). 2. To tell openly (*Locke*). 3. To outlaw by public denunciation (*Shakspeare*).

**PROCLAIMER.** *s.* (from *proclaim*.) One that publishes by authority (*Milton*).

**PROCLAMATION**, a public notice given of any thing of which the king thinks proper to advertise his subjects.

Proclamations are a branch of the king's prerogative, (see **PREROGATIVE**); and have then a binding force, when (as sir Edward Coke observes) they are grounded upon and enforce the laws of the realm. For, though the making of laws is entirely the work of a distinct part, the legislative branch of the sovereign power, yet the manner, time, and circumstances of putting those laws in execution, must frequently be left to the discretion of the executive magistrate. And therefore his constitutions or edicts, concerning those points which we call proclamations, are binding upon the subject, where they do not either contradict the old laws, or tend to establish new ones; but only enforce the execution of such laws as are already in being, in such manner as the king shall judge necessary.

**PROCLIVITY.** *s.* (*proclivitas*, Latin.) 1. Tendency; natural inclination; propension; proneness (*Bramhall*). 2. Readiness; facility of attaining (*Wotton*).

**PROCLIVOUS.** *a.* (*proclivis*, Latin.) Inclined; tending by nature.

**PROCLUS**, surnamed Diadocus, a Greek philosopher and mathematician, was born in Lycia, and lived about the year 500. He was the disciple of Syrianus, and had a great share in the friendship of the emperor Anastasius. It is said, that when Vitalian laid siege to Constantinople, Proclus burnt his ships with large brazen speculums. This philosopher was a pagan, and wrote against the Christian religion. There are still extant his Commentaries on some of Plato's books, and a tedious commentary on the first two books of Euclid's Elements. The latter work has been translated into English by Mr Thomas Taylor.

**PROCONSUL**, a Roman magistrate, sent to govern a province with consular authority. The proconsuls were appointed out of the body of the senate; and usually as the year of any one's consulate expired, he was sent proconsul into some province. The proconsuls decided cases of equity and justice, either privately in their pretorium or palace, where they received petitions, heard complaints, granted writs under their seal, and the like; or else publicly, in the common hall, with the usual formalities observed in the court of judicature at Rome. They had besides, by virtue of their edicts, the power of ordering all things relating to the tribunes, taxes, contributions, and provisions of corn and money, &c. Their office lasted only a year. See **CONSUL**.

**PROCONSULSHIP**, the office of a proconsul.

**PROCOPIUS**, a celebrated officer of a noble family in Cilicia. He was related to the emperor Julian, and lived with him in great intimacy. After he had signalized himself under Julian and his successor, he retired from

the Roman provinces among the barbarians in the Thracian Chersonesus, and proclaimed himself master of the eastern empire. His usurpation was universally acknowledged, but fortune changed, and Procopius was defeated in Phrygia, and abandoned by his army. His head was cut off, and carried to Valentinian, in Gaul, A. D. 366. Procopius was slain in the 42d year of his age.

**PROCOPIUS** of Cæsarea, an historian in great reputation under Justinian, and secretary to Belisarius in all his wars.—His history contains eight books, two of the Persian war, as many of the wars of the Vandals, and four of the Goths. It was published at Paris in 1662, in 2 vols. folio.

**TO PROCRASTINATE.** *v. a.* (*procrastinor*, Lat.) To defer; to delay; to put off from day to day (*Shakspeare*).

**TO PROCRASTINATE.** *v. n.* To be dilatory (*Swift*).

**PROCRASTINATION.** *s.* (*procrastinatio*, Latin.) Delay; dilatoriness (*Decay of Piety*).

**PROCRASTINATOR.** *s.* (from *procrastinate*.) A dilatory person.

**PROCREANT.** *a.* (*procreans*, Lat.) Productive; pregnant (*Shakspeare*).

**TO PROCREATE.** *v. a.* (*procreo*, Latin.) To generate; to produce (*Bentley*).

**PROCREATION.** *s.* (*procreatio*, Latin.) Generation; production (*Raleigh*).

**PROCREATIVE.** *a.* (from *procreate*.) Generative; productive (*Hale*).

**PROCREATIVENESS.** *s.* (from *procreate*.) Power of generation (*Decay of Piety*).

**PROCREATOR.** *s.* (from *procreate*.) Generator; begetter.

**PROCRUSTES**, a famous robber of Attica, called also Polypemon, who was killed by Theseus, near the Cephissus. He tied travellers on a bed, and, if their length exceeded that of the bed, he used to cut part off, but if they were shorter, he had them stretched to make their length equal to it.

**PROCTALGIA.** (*πρωκταλγια*, from *πρωτος*, the fundament, and *αλγος*, pain.) A violent pain at the anus. It is mostly symptomatic of some disease, as piles, scirrhus, prurigo, cancer, &c.

**PROCTITIS.** (*πρωκτιτις*, from *πρωτος*, the anus.) Inflammation of the internal or mucous membrane of the lower part of the rectum.

**PROCTOR**, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law. The proctors of the clergy are the representatives chosen by the clergy to sit in the lower house of convocation; of these there are two for each diocese, and one for each collegiate church.

**PROCTORS**, in the university, are two officers chosen from among the residents to see good orders and exercises daily performed there.

**TO PROCTOR.** *v. a.* (from the noun.) To manage. A cant word (*Shakspeare*).

**PROCTORSHIP.** *s.* (from *proctor*.) Office or dignity of a proctor (*Clarendon*).

**PROCULEIUS**, a Roman knight, celebrated for his fraternal kindness to his brothers Muræna and Scipio, after they had forfeited their estates, and incurred the displeasure of Augustus for siding with young Pompey. He was sent by Augustus to Cleopatra, to endeavour to bring her alive into his presence, but to no purpose. He destroyed himself when labouring under a heavy disease.

**PROCUMBENT.** *a.* (*procumbens*, Lat.) Lying down; prone.

**PROCUMBENT STEM.** Horizontaliter supraterram. Philos. Bot. Debilis terræ innitens. Delin. Pl.—Unable to support itself, and therefore lying upon the ground—but without putting forth roots. (See *REPENT*.) The procumbent, trailing, or prostrate stem, as it is sometimes called, is exemplified in convolvulus soldanella.

**PROCURABLE.** *a.* (from *procure*.) To be procured; obtainable; acquirable (*Boyle*).

**PROCURACY.** *s.* (from *procure*.) The management of any thing.

**PROCURATION.** *s.* (from *procure*.) The act of procuring (*Woodward*).

**PROCURATOR**, a person who has a charge committed to him to act for another. Thus the proxies of the lords in parliament are, in our law-books, called procurators; the bishops are sometimes called procuratores ecclesiarum; and the representatives sent by the clergy to convocation, procuratores clerici. The word is also used for a vicar or lieutenant; and we read of a procurator regni, who was an ancient magistrate. Those who manage causes in Doctors' Commons are also called procurators or proctors. In our statutes, he who gathers the fruits of a benefice for another is particularly called a procurator, and the instrument empowering him to receive them is termed a procuracy.

**PROCURATORIAL.** *a.* (from *procurator*.) Made by a proctor (*Ayliffe*).

**PROCURATORY.** *a.* (from *procurator*.) Tending to procuration.

**TO PROCURE.** *v. a.* (*procuro*, Lat.) 1. To manage; to transact for another. 2. To obtain; to acquire (*Milton*). 3. To persuade; to prevail on (*Herbert*). 4. To contrive; to forward (*Shakspeare*).

**TO PROCURE.** *v. n.* To bawd; to pimp (*Dryden*).

**PROCUREMENT.** *s.* The act of procuring (*Dryden*).

**PROCURER.** *s.* (from *procure*.) 1. One that gains; obtainer (*Walton*). 2. Pimp; pander (*South*).

**PROCURESS.** *s.* (from *procure*.) A bawd (*Spectator*).

**PROCYON**, in astronomy, a fixed star of the second magnitude in the constellation called canis minor. See *CANIS*.

**PRODANO**, an island in the Mediterranean, near the W. coast of the Morea, formerly called Sphacteria. It is 36 miles S.S.E. of Zante. Lon. 21. 24 E. Lat. 37. 15 N.

**PRODICUS**, a sophist and rhetorician of the isle of Cos, flourished about 396 B. C.

He taught at Athens, and had for disciples Euripides, Socrates, Theramenes, and Isocrates. The Athenians put him to death on pretence that he corrupted the morals of their youth.

**PRODIGAL**. *a.* (*prodigus*, Lat.) Profuse; wasteful; expensive; lavish (*Philips*).

**PRODIGAL**. *s.* A waster; a spendthrift (*Dryden*).

**PRODIGALITY**. *s.* (*prodigalité*, French.) Extravagance; profusion; waste; excessive liberality (*Glanville*).

**PRODIGALLY**. *ad.* (from *prodigal*.) Profusely; wastefully; extravagantly (*Dryden*).

**PRODIGIOUS**. *a.* (*prodigiosus*, Latin.) Amazing; astonishing; such as may seem a prodigy; enormous; monstrous (*Bacon*).

**PRODIGIOUSLY**. *ad.* Amazingly; astonishingly; portentously; enormously (*Ray*).

**PRODIGIOUSNESS**. *s.* (from *prodigious*.) Enormousness; portentousness; amazing qualities.

**PRODIGY**. *s.* (*prodigium*, Lat.) 1. Any thing out of the ordinary process of nature, from which omens are drawn; portent (*Addison*). 2. Monster (*Ben Jonson*). 3. Any thing astonishing for good or bad (*Spectator*).

**PRODITION**. *s.* (*proditio*, Lat.) Treason; treachery (*Ainsworth*).

**PRODITOR**. *s.* (Latin.) A traitor: not in use (*Shakspeare*).

**PRODITORIOUS**. *a.* (from *proditor*, Lat.) 1. Traitorous; treacherous; perfidious: not in use (*Daniel*). 2. Apt to make discoveries (*Wotton*).

**To PRODUCE**. *v. a.* (*produco*, Lat.) 1. To offer to the view or notice (*Isaiah*). 2. To exhibit to the public (*Swift*). 3. To bring as an evidence (*Shakspeare*). 4. To bear; to bring forth, as a vegetable (*Sandys*). 5. To cause; to effect; to generate; to beget (*Bacon*).

**PRODUCE**. *s.* (from the noun.) 1. Product; that which any thing yields or brings (*Dryden*). 2. Amount; profit; gain; emergent sum or quantity (*Addison*).

**PRODUCENT**. *s.* (from *produce*.) One that exhibits; one that offers (*Ayliffe*).

**PRODUCER**. *s.* (from *produce*.) One that generates or produces (*Suckling*).

**PRODUCIBLE**. *a.* (from *produce*.) 1. Such as may be exhibited (*South*). 2. Such as may be generated or made (*Boyle*).

**PRODUCIBLENESS**. *s.* (from *producibile*.) The state of being producible (*Boyle*).

**PRODUCT**. *s.* (*productus*, Lat.) 1. Something produced by nature, as fruits, grain, metals (*Spectator*). 2. Work; composition (*Watts*). 3. Thing consequential; effect (*Milton*).

**PRODUCT**, in arithmetic, or algebra, is the factum of two numbers, or quantities, or the quantity arising from, or produced by, the multiplication of two or more numbers, &c. together. Thus, 48 is the product of 6 multiplied by 8.—In multiplication, unity is in proportion to one factor, as the other factor is to the product. So 1:6::8:48.

In algebra, the product of simple quantities

is expressed by joining the letters together like a word, and prefixing the product of the numerical coefficients: so the product of *a* and *b* is *ab*, of *3a* and *4bc* is *12 abc*. But the product of compound factors or quantities is expressed by setting the sign of multiplication between them, and binding each compound factor in a vinculum: so the product of *2a + 3b* and *a - 4c* is  $2a + 3b \times a - 4c$ , or  $(2a + 3b) \times (a - 4c)$ .

In geometry, a rectangle answers to a product, its length and breadth being the two factors; because the numbers expressing the length and breadth being multiplied together produce the content or area of the rectangle.

**PRODUCTILE**. *a.* (from *produco*, Lat.) Which may be produced, or drawn out at length.

**PRODUCTION**. *s.* (from *product*.) 1. The act of producing (*Dryden*). 2. The thing produced; fruit; product (*Swift*). 3. Composition; work of art or study (*Swift*).

**PRODUCTIVE**. *a.* (from *produce*.) Having the power to produce; fertile; generative; efficient (*Milton*).

**PROEDRI**, among the Athenians, were magistrates, who had the first seats at the public assemblies, and whose office it was to propose at each assembly the things to be deliberated upon and determined. Their office always ended with the meeting. Their number was nine so long as the tribes were ten in number.

**PRO'EM**. *s.* (*προοίμιον*) Preface; introduction (*Swift*).

**PROFANATION**. *s.* (from *profano*, Lat.) 1. The act of violating any thing sacred (*Shakspeare*). 2. Irreverence to holy things or persons (*Shakspeare*).

**PROFANE**. *a.* (*profane*, Fr. from *profanus*, Lat.) 1. Irreverent to sacred names or things (*South*). 2. Not sacred; secular (*Burnet*). 3. Polluted; not pure (*Raleigh*). 4. Not purified by holy rites (*Dryden*).

**To PROFANE**. *v. a.* (*profano*, Latin; *profaner*, Fr.) 1. To violate; to pollute (*Milton*). 2. To put to wrong use (*Shakspeare*).

**PROFANELY**. *ad.* (from *profane*.) With irreverence to sacred names or things (*Esdraus*).

**PROFANENESS**. *s.* (from *profane*.) Irreverence of what is sacred (*Dryden*).

**PROFANER**. *s.* (from *profane*.) Polluter; violater (*Hooker*).

**PROFECTION**. *s.* (*profectio*, Lat.) Advancement; progression (*Brown*).

**To PROFESS**. *v. a.* (*professer*, Fr. from *professus*, Lat.) 1. To declare himself in strong terms of any opinion or character (*Milton*). 2. To make a show of any sentiments by loud declaration (*Shakspeare*). 3. To declare publicly one's skill in any art or science, so as to invite employment (*Shakspeare*).

**To PROFESS**. *v. m.* 1. To declare openly (*Titus*). 2. To enter into a state of life by a public declaration (*Dayton*). 3. To declare friendship: not in use (*Shakspeare*).

**PROFESSEDLY**. *ad.* (from *professed*.) According to open declaration made by himself (*Dryden*).

## PRO

**PROFESSION.** *s.* (from *profess.*) 1. Calling; vocation; known employment (*Sprat*). 2. Declaration (*Swift*). 3. The act of declaring one's self of any party or opinion (*Tillotson*).

**PROFESSIONAL.** *a.* (from *profession.*) Relating to a particular calling or profession (*Clarissa*).

**PROFESSOR.** *s.* (*professeur*, Fr.) 1. One who declares himself of any opinion or party (*Bacon*). 2. One who publicly practises or teaches an art (*Swift*). 3. One who is visibly religious (*Locke*).

**PROFESSORSHIP.** *s.* (from *professor.*) The station or office of a public teacher (*Walton*).

**TO PROFFER.** *v. a.* (*profero*, Lat.) 1. To propose; to offer to acceptance (*Spenser*). 2. To attempt of one's own accord (*Milton*).

**PROFFER.** *s.* (from the verb.) 1. Offer made; something proposed to acceptance (*Clarendon*). 2. Essay; attempt (*Bacon*).

**PROFFERER.** *s.* (from *proffer.*) He that offers (*Collier*).

**PROFICIENCE. PROFICIENCY.** *s.* (from *proficio*, Latin.) Profit; advancement in any thing; improvement gained (*Rogers*).

**PROFICIENT.** *s.* (*proficiens*, Lat.) One who has made advances in any study or business (*Boyle*).

**PROFICUOUS.** *a.* (*proficiuus*, Lat.) Advantageous; useful (*Philips*).

**PROFILE** in architecture, the draught of a building, fortification, &c. wherein are expressed the several heights, widths, and thicknesses, such as they would appear, were the building cut down perpendicularly from the roof to the foundation.

**PROFILE** also denotes the outline of a figure, building, member of architecture, &c. Hence profiling sometimes denotes designing or describing the member with the rule, compass, &c.

**PROFILE** in sculpture and painting, denotes a head, portrait, &c. when represented side ways, or in a side view. On almost all medals, faces are represented in profile.

**PROFIT.** *s.* (*profit*, Fr.) 1. Gain; pecuniary advantage (*Swift*). 2. Advantage; accession of good (*Bacon*). 3. Improvement; advancement; proficiency.

**TO PROFIT.** *v. a.* (*profiter*, Fr.) 1. To benefit; to advantage (*Job*). 2. To improve; to advance (*Dryden*).

**TO PROFIT.** *v. n.* 1. To gain advantage (*Arbuthnot*). 2. To make improvement (*Dryden*). 3. To be of use or advantage (*Prior*).

**PROFITABLE.** *a.* (*profitable*, Fr. from *profit*.) 1. Gainful; lucrative (*Bacon*). 2. Useful; advantageous (*Arbuthnot*).

**PROFITABLENESS.** *s.* (from *profitable*.) 1. Gainfulness. 2. Usefulness; advantageousness (*More*).

**PROFITABLY.** *ad.* (from *profitable*.) 1. Gainfully. 2. Advantageously; usefully (*Wake*).

**PROFITLESS.** *a.* (from *profit*.) Void of gain or advantage (*Shakspeare*).

## PRO

**PROFLIGATE.** *a.* (*profligatus*, Latin.) Abandoned; lost to virtue and decency; shameless (*Roscommon*).

**PROFLIGATE.** *s.* An abandoned shameless wretch (*Swift*).

**TO PROFLIGATE.** *v. a.* (*profligo*, Latin.) To drive away; not used (*Harvey*).

**PROFLIGATELY.** *ad.* (from *profligate*.) Shamelessly (*Swift*).

**PROFLIGATENESS.** *s.* (from *profligate*.) The quality of being profligate.

**PROFLUENCE.** *s.* (from *profluent*.) Progress; course (*Watton*).

**PROFLUVIA.** (from *profluo*, to run down.) Fluxes. The fifth order in the class pyrexiae of Cullen's nosology, characterized by pyrexia, with increased excretions.

**PROFLUVII CORTEX.** See **CONESSI CORTEX**.

**PROFLUENT.** *a.* (from *profluens*, Lat.) Flowing forward (*Milton*).

**PROFOUND.** *a.* (*profundus*, Latin.) 1. Deep; descending far below the surface; low with respect to the neighbouring places (*Milton*). 2. Intellectually deep; not obvious to the mind: as, *a profound treatise*. 3. Lowly; humble; submissive; submissive (*Duppa*). 4. Learned beyond the common reach (*Hooker*). 5. Deep in contrivance (*Hosea*). 6. Having hidden qualities (*Shakspeare*).

**PROFOUND.** *s.* 1. The deep; the main; the sea (*Sandys*). 2. The abyss (*Milton*).

**TO PROFOUND.** *v. n.* (from the noun.) To dive; to penetrate (*Glanville*).

**PROFOUNDLY.** *ad.* (from *profound*.) 1. Deeply; with deep concern (*Shakspeare*). 2. With great degrees of knowledge; with deep insight (*Dryden*).

**PROFOUNDNESS.** *s.* (from *profound*.) 1. Depth of place. 2. Depth of knowledge.

**PROFUNDITY.** *s.* (from *profound*.) Depth of place or knowledge (*Milton*).

**PROFUNDUS.** See **FLEXOR PROFUNDUS PERFORANS**.

**PROFUSE.** *a.* (*profusus*, Lat.) 1. Lavish; too liberal; prodigal (*Addison*). 2. Overabounding; exuberant (*Milton*).

**PROFUSELY.** *ad.* (from *profuse*.) 1. Lavishly; prodigally (*Harte*). 2. With exuberance (*Thomson*).

**PROFUSENESS.** *s.* (from *profuse*.) Lavishness; prodigality (*Aiterbury*).

**PROFUSIO.** A loss of blood. A genus of disease in the class locales and order apocynoses of Cullen.

**PROFUSION.** *s.* (*profusio*, Lat.) 1. Lavishness; prodigality; extravagance (*Rowe*). 2. Lavish expense; superfluous effusion (*Hay*). 3. Abundance; exuberant plenty (*Addison*).

**TO PROG.** *v. n.* A low word. 1. To rob; to steal. 2. To shift meanly for provisions (*L'Estrange*).

**PROG.** *s.* (from the verb.) Victuals; provision of any kind (*Congreve*).

**PROGENERATION.** *s.* (*progenero*, Lat.) The act of begetting; propagation.

**PROGENITOR.** *s.* (*progenitus*, Lat.) A

## PRO

forefather; an ancestor in a direct line (*Addison*).

**PROGENY.** *s.* (*progenio*, old Fr. *progenies*, Latin.) Offspring; race; generation (*Addison*).

**PROGNOSIS.** (*προγνωσις*, from *πρo*, before, and *γινωσκω*, to know.) The judgment of the event of a disease by particular symptoms.

**PROGNOSTIC.** *a.* (*prognostique*, French; *προγνωστικός*.) Foretelling disease or recovery; foreshowing.

**PROGNOSTIC.** *s.* (from the adjective.) 1. The skill of foretelling diseases, or the event of diseases (*Arbuthnot*). 2. A prediction (*Swift*). 3. A token forerunning (*South*).

**PROGNOSTICABLE.** *a.* (from *prognosticate*.) Such as may be foreknown or foretold (*Brown*).

**To PROGNOSTICATE.** *v. a.* (from *prognostic*.) To foretel; to foreshow (*Clarendon*).

**PROGNOSTICATION.** *s.* (from *prognosticate*.) 1. The act of foreknowing or foreshowing (*Burnet*). 2. Foretoken (*Sidney*).

**PROGNOSTICATOR.** *s.* (from *prognosticate*.) Foreteller; foreknower (*Government of the Tongue*).

**PROGRAMMA**, anciently signified a letter sealed with the king's seal.

**PROGRAMMA** is also a university term for a billet or advertisement, posted up or given into the hand, by way of invitation to an oration, &c. containing the argument, or so much as is necessary for understanding it.

**PROGRESS.** *s.* (*progrés*, Fr. from *progressus*, Latin.) 1. Course; procession; passage (*Shakspeare*). 2. Advancement; motion forward (*Bacon*). 3. Intellectual improvement; advancement in knowledge; proficiency (*Locke*). 4. Removal from one place to another (*Denham*). 5. A journey of state; a circuit (*Bacon*).

**To PROGRESS.** *v. n.* (*progredior*, Lat.) To move forward; to pass: not used (*Shakspeare*).

**PROGRESSION.** *s.* (*progressio*, Latin.) 1. Proportional process; regular and gradual advance (*Newton*). 2. Motion forward (*Brown*). 3. Course; passage (*Shakspeare*). 4. Intellectual advance (*Locke*).

**PROGRESSION**, in arithmetic and algebra, an orderly advancing or proceeding in the same manner, course, tenor, proportion, &c.

Progression is either arithmetical, or geometrical.

*Arithmetical progression*, is a series of quantities proceeding by continued equal differences, either increasing or decreasing. Thus,

increasing 1, 3, 5, 7, 9, &c. or  
decreasing 21, 18, 15, 12, 9, &c.

where the former progression increases continually by the common difference 2, and the latter series or progression decreases continually by the common difference 3.

*Geometrical progression*, is a series of quantities proceeding in the same continual ratio or proportion, either increasing or decreasing; or it is a series of quantities that are con-

## PRO

tinually proportional; or which increase by one common multiplier, or decrease by one common divisor; which common multiplier or divisor is called the common ratio. As,

increasing, 1, 2, 4, 8, 16, &c.

decreasing, 81, 27, 9, 3, 1, &c.;

where the former progression increases continually by the common multiplier 2, and the latter decreases by the common divisor 3.

Or ascending,  $a$ ,  $ra$ ,  $r^2a$ ,  $r^3a$ , &c.

or descending,  $a$ ,  $\frac{a}{r}$ ,  $\frac{a}{r^2}$ ,  $\frac{a}{r^3}$ , &c.;

where the first term is  $a$ , and common ratio  $r$ . See ARITHMETICAL and GEOMETRICAL.

**PROGRESSIONAL.** *a.* (from *progression*.) Such as are in a state of increase or advance (*Brown*).

**PROGRESSIVE.** *a.* (*progressif*, French.) Going forward; advancing (*Brown*).

**PROGRESSIVE**, in music, an epithet properly applied to lessons expressly composed for the purpose of practical improvement, and which are so constructed in point of increasing execution, as to lead the practitioner by insensible degrees to those difficulties which he could not well encounter without such preparatory exercises. In music, as in the other arts and sciences, the path to improvement has been greatly smoothed, and the labour of the tutor much abridged; by those simple introductory precepts, and practical examples, which some of the first professors have deigned to furnish: and excellence has in consequence been more generally attained than in former ages, when the early advances of the juvenile pupil were less consulted by the learned and ingenious.

**PROGRESSIVE NOTES**, those which succeed each other, either in ascent or descent, by those degrees the settled order of which constitutes the key of the composition, or of the movement, or the passage, in which they take place.

**PROGRESSIVELY.** *ad.* (from *progressive*.) By gradual steps or regular course (*Holder*).

**PROGRESSIVENESS.** *s.* (from *progressive*.) The state of advancing.

**To PROHIBIT.** *v. a.* (*prohibeo*, Latin.) 1. To forbid; to interdict by authority (*Sidney*). 2. To debar; to hinder (*Milton*).

**PROHIBITER.** *s.* (from *prohibit*.) Forbiddier; interdicter.

**PROHIBITION.** *s.* (*prohibition*, French; *prohibitio*, Lat.) Forbiddance; interdict; act of forbidding (*Tillotson*).

**PROHIBITORY.** *a.* (from *prohibit*.) Implying prohibition; forbidding (*Ayliffe*).

**To PROJE/CT.** *v. a.* (*projectus*, Latin.) 1. To throw out; to cast forward (*Pope*). 2. To exhibit a form, as of the image thrown on a mirror (*Dryden*). 3. (*projetter*, Fr.) To scheme; to form in the mind; to contrive.

**To PROJE/CT.** *v. n.* To jut out; to shoot forward; to shoot beyond something next it.

# PROJECTILES.

**PROJECT.** *s.* (*projet*, Fr. from the verb.) Scheme; design; contrivance (*Rogers*).

**PROJECTILE.** *a.* (*projectile*, Fr.) Impelled forward (*Arbuthnot*).

**PROJECTILE.** *s.* (from the adj.) A body put in motion (*Cheyne*).

**PROJECTILES** is the name for that part of mechanical philosophy which treats of the motion of bodies any how projected from the surface of this earth, and influenced by the action of terrestrial gravity.

It is demonstrated in the physical part of astronomy that a body so projected must describe a conic section, having the centre of the earth in one focus; and that it will describe round that focus areas proportional to the times. And it follows from the principles of that science, that if the velocity of projection exceeds 36700 feet in a second, the body (if not resisted by the air) would describe a hyperbola; if it be just 36700, it would describe a parabola; and if it be less than this, it would describe an ellipsis. If projected directly upwards, in the first case, it would never return, but proceed for ever; its velocity continually diminishing, but never becoming less than an assignable portion of the excess of the initial velocity above 36700 feet in a second; in the second case, it would never return, its velocity would diminish without end, but never be extinguished. In the third case, it would proceed till its velocity was reduced to an assignable portion of the difference between 36700 and its initial velocity; and would then return, regaining its velocity by the same degrees, and in the same places, as it lost it. These are necessary consequences of a gravity directed to the centre of the earth, and inversely proportional to the square of the distance. But in the greatest projections that we are able to make, the gravitations are so nearly equal, and in directions so nearly parallel, that it would be ridiculous affectation to pay any regard to the deviations from equality and parallelism. A bullet rising a mile above the surface of the earth, loses only one two-thousandth of its weight, and a horizontal range of four miles makes only  $\frac{1}{4}$  of deviation from parallelism.

The action of gravitation is therefore assumed as equal and parallel, through the whole course of the motion of a projectile; and from this assumption, Galileo, the father of dynamical science, demonstrated that the path of a projectile, as a bullet thrown from a gun, is a parabola; leaving the resistance of the air out of the consideration.

Yet the effects of this resistance are by far too great to be neglected by a careful investigator. For Mr. Robins has shown that, in some cases, this resistance to a cannon ball amounts to more than 20 times the weight of the ball; and Dr. Hutton, having prosecuted this subject far beyond any former example, sometimes found this resistance amount to near 100 times the weight of the ball, viz. when it moved with a velocity of 2000 feet per second, which is a rate of almost 23 miles in a minute. What errors then may not be expected from an hypothesis which neglects this force, as inconsiderable! Indeed it is easy to show, that the path of such projectiles is neither a parabola nor nearly a parabola. For, by that theory, if the ball, in the instance last mentioned, flew in the curve of a parabola, its horizontal range, at  $45^\circ$  elevation,

would be found to be almost 24 miles; whereas it often happens that the ball, with such a velocity, ranges far short of even one mile.

Indeed the falseness of this hypothesis almost appears at sight, even in projectiles slow enough to have their motion traced by the eye; for they are seen to descend through a curve manifestly shorter and more inclined to the horizon than that in which they ascended, and the highest point of their flight, or the vertex of the curve, is much nearer to the place where they fall on the ground, than to that from whence they were at first discharged. These things cannot for a moment be doubted of by any one, who in a proper situation views the flight of stones, arrows, or shells, thrown to any considerable distance.

Mr. Robins has not only detected the errors of the parabolic theory of gunnery, which takes no account of the resistance of the air, but shows how to compute the real range of resisted bodies. But for the method which he proposes, and the tables he has computed for this purpose, see his *Tracts of Gunnery*, p. 183, &c. vol. I. and Euler's *Commentary* on the same, translated by Mr. Hugh Brown, in 1777.

We have already treated this subject pretty copiously under the word *Gunnery*; but we therein spoke of some expected investigations of Dr. Hutton, on this interesting topic, part of which, as they have appeared in the third volume of the doctor's valuable *Course of Mathematics*, may very advantageously to our scientific readers be introduced here.

In conclusion, from the experiments of 1775, the following important deductions were fairly drawn and stated, viz.

- 1st, It is made evident by these experiments, that gunpowder fires almost instantaneously.
- 2dly, The velocities communicated to shot of the same weight, with different charges of powder, are nearly as the square roots of those charges.
- 3dly, And when shot of different weights are fired with the same charge of powder, the velocities communicated to them are nearly in the inverse ratio of the square roots of their weights.
- 4thly, So that, in general, shot which are of different weights, and impelled by the firing of different charges of powder, acquire velocities which are directly as the square roots of the charges of powder, and inversely as the square roots of the weights of the shot.
- 5thly, It would therefore be a great improvement in artillery, occasionally to make use of shot of a long shape, or of heavier matter, as lead; for thus the momentum of a shot, when discharged with the same charge of powder, would be increased in the ratio of the square root of the weight of the shot; which would both augment proportionally the force of the blow with which it would strike, and the extent of the range to which it would go.
- 6thly, It would also be an improvement, to diminish the windage; since by this means, one third or more of the quantity of powder might be saved.
- 7thly, When the improvements mentioned in the last two articles are considered as both taking place, it appears that about half the quantity of powder might be saved. But, important as this saving may be, it appears to be still exceeded by that of the guns: for thus a small gun may be made to have the effect and execution of another of two or three times its size in the present way, by discharging a long shot of 2 or 3 times the weight of its usual ball, or round shot; and thus

# PROJECTILES.

a small ship might employ shot as heavy as those of the largest now used.

Finally, as these experiments prove the regulations with respect to the weight of powder and shot, when discharged from the same piece of ordnance; so, by making similar experiments with a gun varied in its length, by cutting off from it a certain part, before each set of trials, the effects and general rules for the different lengths of guns may be with certainty determined by them. In short, the principles on which these experiments were made are so fruitful in consequences, that, in conjunction with the effects of the resistance of the medium, they appear to be sufficient for answering all the inquiries of the speculative philosopher, as well as those of the practical artillerist.

Such then was the summary conclusion from the first set of experiments with cannon balls, in the year 1775, and such were the probable advantages to be derived from them. We are not aware however that any alterations were adopted from them by authority in the public service: unless we are to except the instance of carronades, a species of ordnance that was afterwards invented, and in some degree adopted in the public service; for, in this instance, the proprietors of those pieces, by availing themselves of the circumstances of large balls, and very small windage, have, with small charges of powder, and at little expense, been enabled to produce very considerable and useful effects with those light pieces.

The 2d set of these experiments extended through most part of the summer seasons of the years 1783, 1784, 1785, and some in 1786. The objects of this course were numerous and various: but the principal articles as follow: 1. The velocities with which balls are projected by equal charges of powder, from pieces of equal weight and calibre, but of different lengths. 2. The velocities with different charges of powder, the weight and length of the guns being equal. 3. The greatest velocities due to the different lengths of guns, to be ascertained by successively increasing the charge, till the bore should be filled, or till the velocity should decrease again. 4. The effect of varying the weight of the piece; every thing else being the same. 5. The penetrations of balls into blocks of wood. 6. The ranges and times of flight of balls; to compare them with their first velocities, for ascertaining the resistance of the medium. 7. The effect of wads; of different degrees of ramming, or compressing the charge; of different degrees of windage; of different positions of the vent; of chambers and trunnions, and every other circumstance necessary to be known for the improvement of artillery.

An ample account is given of these experiments, and the results deduced from them in the doctor's volume of Tracts published in 1786; some few circumstances only of which can be noted here. In this course, 4 brass guns were employed, very nicely bored and cast on purpose, of different lengths, but equal in all other respects, viz. in weight and bore, &c. The lengths of the bores of the guns were,

the gun N<sup>o</sup> 1, was 15 calibres, length of bore 28.5 in.  
 ..... N<sup>o</sup> 2, .. 20 calibres, ..... 38.4  
 ..... N<sup>o</sup> 3, .. 30 calibres, ..... 57.7  
 ..... N<sup>o</sup> 4, .. 40 calibres, ..... 80.2  
 the calibre of each being 2 $\frac{1}{8}$  inches, and the medium weight of the balls 16 oz. 13 dr.

The mediums of all the experimented velocities of the balls, with which they struck the pendulous block of wood, placed at the distance of 32 feet from the muzzle of the gun, for several charges of powder, were as in the following table,

| Table of initial velocities. |                   |                   |                   |                   |
|------------------------------|-------------------|-------------------|-------------------|-------------------|
| Powder.                      | The guns.         |                   |                   |                   |
| oz.                          | N <sup>o</sup> 1. | N <sup>o</sup> 2. | N <sup>o</sup> 3. | N <sup>o</sup> 4. |
| 2                            | 780               | 835               | 920               | 970               |
| 4                            | 1100              | 1180              | 1300              | 1370              |

| 8                            | 1430              | 1580              | 1790              | 1940              |
| 12                           | 1436              | 1640              | .                 | .                 |
| 14                           | .                 | 1660              | .                 | .                 |
| 16                           | .                 | .                 | 2000              | .                 |
| 18                           | .                 | .                 | .                 | 2200              |

placed in the 1st column, for all the four guns, the numbers denoting so many feet per second. Whence in general it appears how the velocities increase with the charges of powder, for each gun, and also how they increase as the guns are longer, with the same charge, in every instance.

By increasing the quantity of the charges continually, for each gun, it was found that the velocities continued to increase till they arrived at a certain degree, different in each gun; after which, they constantly decreased again, till the bore was quite filled with the charge. The charges of powder when the velocities arrived at their maximum or greatest state were various, as might be expected, according to the lengths of the guns; and the weight of powder, with the length it extended in the bore, and the fractional part of the bore it occupied, are shown in the following table, of the charges for the greatest effect.

| Gun,<br>N <sup>o</sup> . | Length<br>of the<br>bore. | The charge.    |         |                   |
|--------------------------|---------------------------|----------------|---------|-------------------|
|                          |                           | Weight,<br>oz. | Length. |                   |
|                          |                           |                | Inches. | Part of<br>whole. |
| 1                        | 28.5                      | 12             | 8.2     | $\frac{1}{3}$     |
| 2                        | 38.4                      | 14             | 9.5     | $\frac{3}{12}$    |
| 3                        | 57.7                      | 16             | 10.7    | $\frac{1}{6}$     |
| 4                        | 80.2                      | 18             | 12.1    | $\frac{2}{20}$    |

Some few experiments in this course were made to obtain the ranges and times of flight, the mediums of which are exhibited in the following table.

# PROJECTILES.

| Guns.             | Powder. | Balls.  |       | Elevat. gun. | Time of flight. | Range. | First veloc. |
|-------------------|---------|---------|-------|--------------|-----------------|--------|--------------|
|                   |         | Weight. | Diam. |              |                 |        |              |
| N <sup>o</sup> 2. | oz.     | oz. dr. | inch. |              | secs.           | feet.  | feet.        |
|                   | 2       | 16 10   | 1.96  | 45°          | 21.2            | 5109   | 863          |
| ditto.            | 4       | 16 5    | 1.96  | 15           | 9.2             | 4130   | 868          |
| ditto.            | 4       | 16 8    | 1.96  | 15           | 9.2             | 4660   | 1234         |
| ditto.            | 8       | 16 12   | 1.96  | 15           | 14.4            | 6066   | 1644         |
| ditto.            | 12      | 16 12   | 1.95  | 15           | 15.5            | 6700   | 1676         |
| N <sup>o</sup> 3. | 8       | 15 8    | 1.96  | 15           | 10.1            | 5610   | 1938         |

In this table are contained the following concomitant data, determined with a tolerable degree of precision; viz. the weight of the powder, the weight and diameter of the ball, the initial or projectile velocity, the angle of elevation of the gun, the time in seconds of the ball's flight through the air, and its range, or the distance where it fell on the horizontal plane. From which it is hoped that some aid may be derived towards ascertaining the resistance of the medium, and its effects on other elevations, &c. and so afford some means of obtaining easy rules for the cases of practical gunnery; though the completion of this enquiry, for want of time at present, must be referred to another work.

Another subject of enquiry in the foregoing experiments, was, how far the balls would penetrate into solid blocks of elm wood, fired in the direction of the fibres. The following tablet shows the results of a few of the trials that were made with the gun N<sup>o</sup> 2, with the most frequent charges of 2, 4, and 8 ounces of powder; and the mediums of the penetrations, as placed in the last line, are found to be 7, 15, and 20 inches, with those charges. These penetrations are nearly as the numbers

2, 4, 6, or 1, 2, 3; but the charges of powder are as

2, 4, 8, or 1, 2, 4; so that the penetrations are proportional to the charges as far as to 4 ounces, but in a less ratio at 3 ounces; whereas, by the theory of penetrations, the depths ought to be proportional to the charges, or, which is the same thing, as the squares of the velocities. So that it seems the resisting force of the wood is not uniformly or constantly the same, but that it increases a little with the increased velocity of the ball. This may probably be occasioned by the greater quantity of fibres driven before the ball; which may thus increase the spring and resistance of the wood, and prevent the ball from penetrating so deep as it otherwise might do.

| Penetrations of balls into solid elm wood. |      |       |
|--------------------------------------------|------|-------|
| Powder 2                                   | 4    | 8 oz. |
| 7                                          | 16.6 | 18.9  |
|                                            | 13.5 | 21.2  |
|                                            |      | 18.1  |
|                                            |      | 20.8  |
|                                            |      | 20.5  |
| Means 7                                    | 15   | 20    |

From a general inspection of this second course of these experiments, it appears that all the de-

ductions and observations made on the former course are here corroborated and strengthened, respecting the velocities and weights of the balls, and charges of powder, &c. It further appears also that the velocity of the ball increases with the increase of charge only to a certain point, which is peculiar to each gun, where it is greatest; and that by further increasing the charge, the velocity gradually diminishes, till the bore is quite full of powder. That this charge for the greatest velocity is greater as the gun is longer, but yet not greater in so high a proportion as the length of the gun is; so that the part of the bore filled with powder, bears a less proportion to the whole bore in the long guns, than it does in the shorter ones; the part which is filled being indeed nearly in the inverse ratio of the square root of the empty part.

It appears that the velocity, with equal charges, always increases as the gun is longer; though the increase in velocity is but very small in comparison to the increase in length; the velocities being in a ratio somewhat less than that of the square roots of the length of the bore, but greater than that of the cube roots of the same, and is indeed nearly in the middle ratio between the two.

It appears, from the table of ranges, that the range increases in a much lower ratio than the velocity, the gun and elevation being the same. And when this is compared with the proportion of the velocity and length of gun in the last paragraph, it is evident that we gain extremely little in the range by a great increase in the length of the gun, with the same charge of powder. In fact, the range is nearly as the 5th root of the length of the bore; which is so small an increase, as to amount only to about a 7th part more range for a double length of gun. From the same table it also appears, that the time of the ball's flight is nearly as the range; the gun and elevation being the same.

It has been found, by these experiments, that no difference is caused in the velocity, or range, by varying the weight of the gun, nor by the use of wads, nor by different degrees of ramming, nor by firing the charge of powder in different parts of it. But that a very great difference in the velocity arises from a small degree in the windage: indeed with the usual established windage only, viz. about  $\frac{1}{10}$  of the calibre, no less than between  $\frac{1}{2}$  and  $\frac{1}{4}$  of the powder escapes and is lost: and as the balls are often smaller than the regulated size, it frequently happens that half the powder is lost by unnecessary windage.

It appears too that the resisting force of wood, to balls fired into it, is not constant: and that the depths penetrated by balls, with different velocities or charges, are nearly as the logarithms of the charges, instead of being as the charges them-

# PROJECTILES.

velocities, or, which is the same thing, as the square of the velocity. Lastly, these and most other experiments show, that balls are greatly deflected from the direction in which they are projected: and that as much as 300 or 400 yards in a range of a mile, or almost  $\frac{1}{4}$  of the range.

We have before adverted to a 3d set of experiments, of still more importance, with respect to

the resistance of the medium, than any of the former; but, till the publication of those experiments, we cannot avail ourselves of all the discoveries they contain. In the mean time, however, we may extract from them the three following tables of resistances, for three different sizes of balls, and for velocities between 100 feet and 2000 feet per second of time.

| TABLE I.                                                                  |              |                |                 |         | TABLE II.                                                   |                   |                  | TABLE III.                                                              |                   |                  |

| 1800                                                                      | 82.44        | 1331           | -5              |         | 1750                                                        | 171               | 6                |                                                                         |                   |                  |
| 1900                                                                      | 90.44        | 1447           | -6              |         | 1800                                                        | 176               | 5                |                                                                         |                   |                  |
| 2000                                                                      | 98.06        | 1569           |                 |         |                                                             |                   |                  |                                                                         |                   |                  |

PROB. I.—To determine the resistance of the medium against a ball of any other size, moving with any of the velocities given in the foregoing tables.

The analogy among the numbers in all these tables is very remarkable and uniform, the same general laws running through them all. The same laws are also observable as in the table of resistances near the end of the 2d volume, particularly the 1st and 2d remarks immediately following that table, viz. that the resistances increase in a higher proportion than the square of the velocities with the same body; and that the resistances also increase in a rather higher ratio than the surfaces, with different bodies, but the same velocity. Yet this latter case, viz. the ratios of the resistances and of the surfaces, or of the squares of the diameters, which is the same thing, are so nearly alike, that they may be considered as equal to each other in any calculations relating to artillery practice. For example, suppose it were required to determine what would be the resistance of the air against a 24 lb. ball discharged with a velocity of 2000 feet per second of time. Now, by the 1st of the foregoing tables, the ball of 1.965 inches diameter, when moving with the velocity 2000, suffered a resistance of 98 lb.: then, since the resistances, with the same velocity, are as the surfaces; and the surfaces are as the squares of the diameters; and the diameters being

1.965 and 5.6, the squares of which are 3.86 and 31.36, therefore as 3.86:31.36::98 lb.:796 lb.; that is, the 24 lb. ball would suffer the enormous resistance of 796 lb. in its flight, in opposition to the direction of its motion!

And, in general, if the diameter\* of any proposed ball be denoted by  $d$ , and  $r$  denote the resistance in the 1st table due to the proposed

velocity of the 1.965 ball; then  $\frac{d^2 r}{3.86}$  will denote

the resistance with the same velocity against the ball whose diameter is  $d$ ; or it is nearly  $\frac{1}{8} d^2 r$ , which is but the 28th part greater than the former.

PROB. II.—To assign a rule for determining the resistance due to any indeterminate velocity of a given ball.

This problem is very difficult to perform near the truth, on account of the variable ratio which the resistance bears to the velocity, increasing always more and more above that of the square of the velocity, at least to a certain extent; and indeed it appears that there is no single integral power whatever of the velocity, or no expression of the velocity in one term only, that can be proportional to the resistances throughout. It is true indeed, that such an expression can be assigned by means of a fractional power of the velocity, or rather one whose index is a mixed number, viz.

# PROJECTILES.

$\frac{1}{10}$  or  $2 \cdot 1$ ; thus,  $\frac{v^2}{5400} =$  the resistance, is a formula in one term only, which will answer to all the numbers in the first table of resistances very nearly, and consequently, by means of the ratio of the squares of the diameters of the balls, for any other balls whatever. This formula then, though serving quite well for some particular resistance, or even for constructing a complete series or table of resistances, is not proper for the use of problems in which fluxions and fluents are concerned, on account of the mixed number  $2 \frac{1}{10}$ , in the index of the velocity  $v$ .

We must therefore have recourse to an expression in two terms, or a formula containing two integral powers of the velocity, as  $v^2$  and  $v$ , the 1st and 2d powers, affected with general coefficients  $m$  and  $n$ , as  $mv^2 + nv = r$ , the resistance. Now, to determine the general numerical values of the coefficients  $m$  and  $n$ , we must adapt this general expression  $mv^2 + nv = r$ , to two particular cases of velocity, at a convenient distance from each other, in one of the foregoing tables of resistances, as the first for instance. Now, after making several trials in this way, Dr. Hutton found that the two velocities of 500 and 1000 answer the general purpose better than any other that has been tried. Thus then, employing these two cases, we must first make  $v = 500$ , and  $r = 4 \frac{1}{2}$  lb, its correspondent resistance, and then again  $v = 1000$ , and  $r = 21 \cdot 88$  lb. the resistance belonging to it: this will give two equations, by which the general value of  $m$  and of  $n$  will be determined. Thus then the two equations being

$$500^2 m + 500 n = 4 \cdot 5,$$

$$\text{and } 1000^2 m + 1000 n = 21 \cdot 88;$$

dividing the 1st by 500, and  $\frac{1}{2}$   $500 m + n = \cdot 009$ , the 2d by 1000, they are  $\frac{1}{2}$   $1000 m + n = \cdot 02188$ ; the dif of these is  $\dots\dots\dots 500 m = \cdot 01288$ , and therefore div. by 500, gives  $m = \cdot 00002576$ ; hence  $n = \cdot 009 - 500 m = \cdot 009 - \cdot 01288 = - \cdot 00388 = n$ . Hence then the general formula will be  $\cdot 00002576 v^2 - \cdot 00388 v = r$ , the resistance nearly in avoirdupois pounds, in all cases or all velocities whatever.

Now, to find how near to the truth this theorem comes, in every instance in the table, by substituting for  $v$ , in this formula, all the several velocities, 100, 200, 300, &c. to 2000; these give the correspondent values of  $r$ , or the resistances, as in the 2d column of the following table, their velocities being in the first column; and the real experimented resistances are set opposite to them in the 3d or last column of the same. By the comparison of the numbers in these two columns together, it is seen that there are no where any great difference between them, being sometimes a little in excess, and again a little in defect, by very small differences; so that, on the whole, they will nearly balance one another, in any particular instance of the range or flight of a ball, in all degrees of its velocity, from the first or greatest, to the smallest or last. Except in the first two or three numbers, at the beginning of the table, for the velocities 100, 200, 300, for which cases another theorem may be employed. Now, in these three velocities, as well as in all that are smaller, down to nothing, the theorem  $\cdot 00001725 v^2 = r$  the resistance, will very well serve, as it brings out for the first three resistances  $\cdot 17$ , and  $\cdot 69$ , and  $1 \cdot 554$ , differing in the last only by a very small fraction.

| Velocs.<br>or $v$ . | Comput.<br>resists. | Exper.<br>resists. |

| 1900                | $85 \cdot 62$       | $90 \cdot 44$      |
| 2000                | $95 \cdot 28$       | $98 \cdot 06$      |

**Corol. 1.** The foregoing rule  $\cdot 00002576 v^2 - \cdot 00388 v = r$ , denotes the resistance for the ball in the first table, whose diameter is  $1 \cdot 965$ , the square of which is  $3 \cdot 86$ , or almost 4; hence to adapt it to a ball of any other diameter  $d$ , we have only to alter the former in proportion to the squares of the diameters, by which it becomes

$$\frac{dd}{3 \cdot 86} (\cdot 00002576 v^2 - \cdot 00388 v) = (\cdot 00000667 v^2 - \cdot 0010) d^2 = (\cdot 00000000 v^2 - \cdot 0010) d^2,$$

which is the resistance for the ball whose diameter is  $d$ , with the velocity  $v$ .

**Corol. 2.** And, in a similar manner, to adapt the theorem  $\cdot 00001725 v^2 = r$ , for the smaller velocities, to any other size of ball, we must multiply it by  $\frac{dd}{3 \cdot 86}$ , the ratio of the surfaces, by which it becomes  $\cdot 00000447 d^2 v^2 = r$ .

We shall soon take occasion to make some applications in the use of the foregoing formulas, after considering the effects of such velocities in the cases of nonresistances.

**PROB. III.**—To determine the height to which a ball will rise, when fired from a cannon perpendicularly upwards, with a given velocity, in a non-resisting medium, or supposing no resistance in the air.

Any body projected upwards, with a given velocity, will ascend to the height due to the velocity, or the height from which it must naturally fall to acquire that velocity; and the spaces fallen being as the square of the velocities; also 16 feet being the space due to the velocity 32; therefore the space due to any proposed velocity  $v$ , will be found thus, as  $32^2 : 16 :: v^2 : s$  the space, or as  $64 : 1 :: v^2 : \frac{1}{4} v^2 = s$  the space, or the height to which the velocity  $v$  will cause the body to rise, independent of the air's resistance.

**Exam.** For example, if the first or projectile velocity be 2000 feet per second, being nearly the greatest experimented velocity, then the rule  $\frac{1}{4} v^2 = s$  becomes  $\frac{1}{4} \times 2000^2 = 62500$  feet =  $11 \frac{1}{2}$  miles; that is, any body, projected with the velocity 2000

# PROJECTILES.

feet, would ascend nearly 12 miles in height, without resistance.

*Corol.* Because, by art. 88, Projectiles, vol. 2, the greatest range is just double the height due to the projectile velocity, therefore the range, at an elevation of  $45^\circ$ , with the velocity in the last example, would be  $23\frac{1}{2}$  miles, in a nonresisting medium. We shall now see what the effects will be with the resistance of the air.

**PROB. IV.**—To determine the height to which a ball projected upwards, as in the last problem, will ascend, being resisted by the atmosphere.

Putting  $x$  to denote any variable and increasing height ascended by the ball;  $v$  its variable and decreasing velocity there;  $d$  the diameter of the ball, its weight being  $w$ ;  $m = .000003$ , and  $n = .001$ , the coefficients of the two terms denoting the law of the air's resistance. Then  $(mv^2 - nv)d^2$ , by cor. 1. to prob. 2, will be the resistance of the air against the ball in avoirdupois pounds; to which if the weight of the ball be added, then  $(mv - nv)d^2 + w$  will be the whole resistance to the ball's motion; this divided by  $w$ , the weight of the ball in motion, gives  $\frac{(mv^2 - nv)d^2 + w}{w} = \frac{mv^2 - nv}{w} d^2$

+  $\frac{1}{w} = f$  the retarding force. Hence the general formula  $v\dot{v} = 2gf\dot{x}$  (theor. 10. p. 342, vol. 2, edit. 6, Course) becomes  $-v\dot{v} = 2g\dot{x} \times \frac{(mv^2 - nv)d^2 + w}{w}$ , making  $\dot{v}$  negative because  $v$  is decreasing, where  $g = 16$  feet; and hence

$$\dot{x} = -\frac{w}{2g} \times \frac{v\dot{v}}{(mv^2 - nv)d^2 + w} = \frac{-v\dot{v}}{2gmd^2} \times \frac{v\dot{v}}{v^2 - \frac{n}{m}v + \frac{w}{md^2}}$$

Now, for the easier finding the fluent of this, assume  $v - \frac{n}{2m} = z$ ; then  $v = z + \frac{n}{2m}$ , and  $v^2 = z^2 + \frac{n}{m}z + \frac{n^2}{4m^2}$ , and  $v\dot{v} = z\dot{z} + \frac{n}{2m}\dot{z}$ , and  $v^2 - \frac{n}{m}v + \frac{w}{md^2} = z^2 - \frac{n^2}{4m^2} + \frac{w}{md^2}$ ; these being substituted in the above value of  $\dot{x}$ , it becomes

$$\dot{x} = \frac{-w}{2gmd^2} \times \frac{z\dot{z} + \frac{n}{2m}\dot{z}}{z^2 - \frac{n^2}{4m^2} + \frac{w}{md^2}} = \frac{-w}{2gmd^2} \times \frac{z\dot{z} + p\dot{z}}{z^2 + \frac{w}{md^2} - p^2}$$

$= \frac{-w}{2gmd^2} \times \frac{z\dot{z} + p\dot{z}}{z^2 + q^2}$ , putting  $p = \frac{n}{2m}$ , and  $q^2 = \frac{w}{md^2} - p^2$ , or  $p^2 + q^2 = \frac{w}{md^2}$ .

Then the general fluents, taken by the 8th and 11th forms, vol. 2. p. 307, give  $x = \frac{-w}{2gmd^2} \times [\frac{1}{2} \log.$

$$(z^2 + q^2) + \frac{p}{q^2} \times \text{arc to rad. } q \text{ and tan. } z] = \frac{-w}{2gmd^2} \times [\frac{1}{2} \log. (v^2 - \frac{n}{m}v + \frac{w}{md^2}) + \frac{p}{q^2} \times \text{arc to rad. } q$$

and tang.  $v - p$ ]. But, at the beginning of the motion, when the first velocity is  $v$  for instance, and the space  $x = 0$ , this fluent becomes

$$0 = \frac{-w}{2gmd^2} \times [\frac{1}{2} \log. (v^2 - \frac{n}{m}v + \frac{w}{md^2}) + \frac{p}{q^2} \times \text{arc to rad. } q \tan. v - p].$$

Hence by subtraction, and taking  $v = 0$  for the end of the motion, the correct fluent becomes

$$x = \frac{-w}{2gmd^2} \times [\frac{1}{2} \log. (v^2 - \frac{n}{m}v + \frac{w}{md^2}) - \frac{1}{2} \log. \frac{w}{md^2} + \frac{p}{q^2} \times (\text{arc tan. } v - p - \text{arc tan. } -p \text{ to rad. } q)].$$

But as part of this fluent, denoted by  $\frac{p}{q^2} \times$  the dif. of the two arcs to tans.  $v - p$  and  $-p$ , is always very small in comparison with the other preceding terms, they may be omitted without material error in any practical instance; and then the fluent is  $x = \frac{w}{4gmd^2} \times \text{hyp. log.}$

$$v^2 - \frac{n}{m}v + \frac{w}{md^2} \frac{w}{md^2}, \text{ for the utmost height to which}$$

the ball will ascend, when its motion ceases, and is stopped, partly by its own gravity, but chiefly by the resistance of the air.

But now, for the numerical value of the general coefficient  $\frac{w}{4gmd^2}$ , and the term  $\frac{w}{md^2}$ ; because the mass of the ball to the diameter  $d$ , is  $.5236d^3$ , if its specific gravity be  $s$ , its weight will be  $.5236sd^3 = w$ ; therefore  $\frac{w}{d^3} = .5236sd$ , and  $\frac{w}{md^2} =$

$$78540sd, \text{ this divided by } 4g \text{ or } 64, \text{ it gives } \frac{w}{4gmd^2} =$$

$1227.2sd$  for the value of the general coefficient, to any diameter  $d$  and specific gravity  $s$ . And if we further suppose the ball to be cast iron, the specific gravity, or weight of one cubic inch of which is  $.26855$ , it becomes  $330d$ , for that coefficient; also  $78540sd = 21090d = \frac{w}{md^2}$ , and  $\frac{n}{m} = 150$ .

And hence the foregoing fluent becomes  $330d \times \text{hyp. log. } \frac{v^2 - 150v + 21090d}{21090d}$  or  $760d \times \text{com. log.}$

$\frac{v^2 - 150v + 21090d}{21090d}$ , changing the hyperbolic for the common logs. And this is a general expression for the altitude in feet, ascended by any iron ball, whose diameter is  $d$  inches, discharged with any velocity  $v$  feet. So that, substituting any values of  $d$  and  $v$ , the particular heights will be given to which the balls will ascend, which it is evident will be nearly in proportion to the diameter  $d$ .

*Exam. 1.* Suppose the ball be that belonging to the first table of resistances, its weight being 16oz. 13dr. or 1.05lb. and its diameter 1.965 inc. when discharged with the velocity 2000 feet, being nearly the greatest charge for any iron ball. The calculation being made with these values of  $d$  and  $v$ , the height ascended is found to be 2920 feet, or little more than half a mile; though found to be almost 12 miles without the air's resistance. And thus the height may be found for any other diameter and velocity.

*Exam. 2.* Again, for the 24lb. ball, with the same

# PROJECTILES.

velocity 2000, its diameter being  $5.6 = d$ . Here  $760d = 4256$ , and  $\frac{v^2 - 150v + 21090d}{21090d} = \frac{38181}{1181}$ , the log. of which is  $1.50958$ ; theref.  $1.50958 \times 4256 = 6424 = x$  the height, being a little more than a mile.

We may now examine what will be the height ascended, considering the resistance always as the square of the velocity.

**PROB. V.**—To determine the height ascended by a ball projected as in the two foregoing problems; supposing the resistance of the air to be as the square of the velocity.

Here it will be proper to commence with selecting some experimented resistance corresponding to a medium kind of velocity, between the first or greatest velocity and nothing, from which to compute the other general resistances, by considering them as the squares of the velocities. It is proper to assume a near medium velocity and its resistance, because, if we assume or commence with the greatest, or the velocity of projection, and compute from it downwards, the resistances will be everywhere too great, and the altitude ascended much less than just; and, on the other hand, if we assume or commence with a small resistance, and compute from it all the others upwards, they will be much too little, and the computed altitude far too great. But, commencing with a medium degree, as for instance that which has a resistance about the half of the first or greatest resistance, or rather a little more, and computing from that, then all those computed resistances above that will be rather too little, but all those below it too great; by which it will happen, that the defect of the one side will be compensated by the excess on the other, and the final conclusion must be near the truth.

Thus then, if we wish to determine, in this way, the altitude ascended by the ball employed in the 1st table of resistances, when projected with 2000 feet velocity; we perceive by the table, that to the velocity 2000 corresponds the resistance 98 lb. the half of this is 49, to which resistance corresponds the velocity 1400 in the table, and the next greater velocity 1500, with its resistance  $57\frac{1}{4}$ , which will be properest to be employed here. Hence then, for any other velocity  $v$ , in general, it will be, according to the law of the squares of

the velocities, as  $1500^2 : v^2 :: 57\frac{1}{4} : \frac{57\frac{1}{4}v^2}{1500^2} =$

$.000025\frac{1}{4}v^2 = av^2$ , putting  $a = .000025\frac{1}{4}$ , which will denote the air's resistance for any velocity  $v$ , very nearly, counting from 3000.

Now, let  $x$  denote the altitude ascended when the velocity is  $v$ , and  $w$  the weight of the ball: then, as above,  $av^2$  is the resistance from the air, hence  $av^2 + w$  is the whole resisting force, and

$\frac{av^2 + w}{w} = f$  the retarding force;

therefore  $-vv = 2gf\dot{x} = \frac{av^2 + w}{w} \times 2g\dot{x}$ ;

and hence  $\dot{x} = \frac{-w}{2g} \times \frac{vv}{av^2 + w} = \frac{-w}{2ga} \times \frac{vv}{v^2 + \frac{w}{a}}$ ;

the fluent of which, by form 8, is  $\frac{-w}{4ga} \times \text{hyp. log.}$

$(v^2 + \frac{w}{a})$ ; which when  $x=0$ , and  $v=v$  the first or projectile velocity, becomes  $0 = \frac{-w}{4ga} \times \text{hyp. log.}$

$(v^2 + \frac{w}{a})$ ; therefore by subtracting, the correct fluent is  $x = \frac{w}{4ga} \times \text{hyp. log.} \frac{av^2 + w}{av^2 + w}$ , the height  $x$

when the velocity is reduced to  $v$ ; and when  $v=0$ , or the velocity is quite exhausted, this becomes

$\frac{w}{4ga} \times \text{hyp. log.} \frac{av^2 + w}{w}$  for the whole height to which the ball will ascend.

**Ex. 1.** The values of the letters being  $w = 105$  lb.  $4g = 64$ ,  $a = .000025\frac{1}{4}$ , the last expression becomes

$645 \times \text{hyp. log.} \frac{v^2 + 41266}{41266}$ , or  $1484 \times \text{com. log.}$

$\frac{v^2 + 41266}{41266}$ . And here the first velocity  $v$  being

2000, the same expression  $1484 \times \text{log.} \frac{v^2 + 41266}{41266}$

becomes  $1484 \times \text{log. of } 97.93 = 2955$  for the height ascended, on this hypothesis; which was 2920 by the former problem, being nearly the same.

**Ex. 2.** Supposing the same ball to be projected with the velocity of only 1500 feet. Then taking 1100 velocity, whose tabular resistance is 27.6, being next above the half of that for 1500. Hence, as  $1100^2 : v^2 :: 27.6 : .00002375v^2 = av^2$ . This va-

lue of  $a$  substituted in the theorem  $\frac{w}{4ga} \times \text{hyp. log.}$

$\frac{av^2 + w}{w}$ , also 1500 for  $v$ , and 105 for  $w$ , it brings

out  $x = 2728$  for the height in this case, being but a little above the ratio of the square roots of the velocities 2000 and 1500, as that ratio would give only 2560.

**Ex. 3.** To find the height ascended by the first ball, projected with 860 feet velocity. Here taking 600, whose resistance 6.69 is a near medium;

then as  $600^2 : 6.69 :: 1 : .0000186 = a$ . Hence  $\frac{w}{64a}$

$\times \text{hyp. log.} \frac{av^2 + w}{w} = 2334$  the height; which is

less than half the range (5100) at  $45^\circ$  elevation, but more than half the range (4100) at  $15^\circ$  elevation, in p. 161, vol. 2; being indeed nearly a medium between the two.

**Ex. 4.** With the same ball, and 1640 velocity. Assume 1200, whose resistance 34.13 is nearly a medium. Then as  $1200^2 : 34.13 :: 1 : .0000237$

$= a$ . Hence  $\frac{w}{64a} \times \text{h. l.} \frac{av^2 + w}{w} = 2854$ ; again,

less than half the range (6000) by experiment in vol. 2, even with  $15^\circ$  elevation.

**Ex. 5.** For any other ball, whose diameter is  $d$ , and its weight  $w$ , the resistance of the air being

$ad^2v^2 = \frac{d^2v^2}{150000} = bd^2v^2$ , putting  $b = \frac{1}{150000}$ , there-

tarding force will be  $\frac{bd^2v^2 + w}{w}$ , thence  $-vv = 2g\dot{x} \times$

# PROJECTILES.

$\frac{bd^2v^2+w}{w}$ , and  $\dot{x} = \frac{-w}{2g} \times \frac{v}{bd^2v^2+w}$ , and the cor. flu.

$$x = \frac{w}{4gbd^2} \times \text{hyp. log. } \frac{bd^2v^2+w}{bd^2v^2} = \frac{w}{4gbd^2} \times \text{hyp. log.}$$

$\frac{bd^2v^2+w}{w}$  for the whole height when  $v=0$ . Now,

if the ball be a 24 pounder, whose diameter is 5.6,

and its square 31.36; then  $bd^2 = \frac{62.72}{300000} = .0002091$ ,

$$\text{and } \frac{w}{4gbd^2} = \frac{24}{46bd^2} = \frac{3}{8bd^2} = 1794; \text{ and } bd^2v^2 =$$

$$836, \text{ and } \frac{bd^2v^2+w}{w} = \frac{836+24}{24} = \frac{860}{24} = \frac{215}{6}, \text{ there-}$$

$$\text{fore } x = 1794 \times \text{hyp. log. } \frac{215}{6} = 1794 \times 3.57888 =$$

6420, being more than double the height of that of the small ball, or a little more than a mile, and very nearly the same as in the 2d example to prob. 4.

PROB. VI.—To determine the time of the ball's ascending to the height determined in the last problem, by the same projectile velocity as there given.

$$\text{By that prob. } \dot{x} = \frac{-w}{2ga} \times \frac{v}{v^2 + \frac{w}{a}}, \text{ ther. } t = \frac{\dot{x}}{v} =$$

$$\frac{-w}{2ga} \times \frac{v}{v^2 + \frac{w}{a}}; \text{ the fluent of which, by form 11,}$$

$$\text{is } \frac{-w}{2ga} \sqrt{\frac{a}{w}} \times \text{arc to radius } 1 \text{ tang. } \frac{v}{\sqrt{\frac{w}{a}}} = \frac{-1}{2g} \sqrt{\frac{a}{w}}$$

$$\frac{w}{a} \times \text{arc tan. } \frac{v}{\sqrt{\frac{w}{a}}}; \text{ or by correction } t = \frac{1}{2g} \sqrt{\frac{w}{a}}$$

$$\times (\text{arc tang. } \frac{v}{\sqrt{\frac{w}{a}}} - \text{arc tang. } \frac{v}{\sqrt{\frac{w}{a}}}), \text{ the time in}$$

general when the first velocity  $v$  is reduced to  $v$ . And when  $v=0$ , or the velocity ceases, this be-

$$\text{comes } t = \frac{1}{2g} \sqrt{\frac{w}{a}} \times \text{arc to tang. } \frac{v}{\sqrt{\frac{w}{a}}} \text{ for the}$$

time of the whole ascent.

Now, as in the last prob.  $v=2000$ ,  $w=1.05$ ,

$$a = .000025 \frac{229}{9000000}. \text{ Hence } \frac{w}{a} = 41266, \text{ and}$$

$$\sqrt{\frac{w}{a}} = 203.14, \text{ and } \frac{v}{\sqrt{\frac{w}{a}}} = 98.445 \text{ the tangent,}$$

to which corresponds the arc of  $89^\circ 25'$ , whose

$$\text{length is } 1.5606; \text{ then } \frac{1}{2g} \times 203.14 \times 1.5606 =$$

$$\frac{203.14 \times 1.5606}{32} = 9.91, \text{ the whole time of ascent.}$$

Remark. The time of freely ascending to the same height 2955 feet, that is, without the air's resistance, would be  $\sqrt{\frac{2955}{16}} = 13.59$ ; and the time of freely ascending, commencing

with the same velocity 2000, would be  $\frac{v}{2g} =$

$$\frac{2000}{32} = 62 \frac{1}{2} = 1' 2 \frac{1}{2}.$$

PROB. VII.—To determine the same as in problem V. taking into the account the decrease of density in the air as the ball ascends in the atmosphere.

In the preceding problems, relating to the height and time of balls ascending in the atmosphere, the decrease of density in the upper parts of it has been neglected, the whole height ascended by the ball being supposed in air of the same density as at the earth's surface. But it is well known that the atmosphere must and does decrease in density upwards, in a very rapid degree; so much so indeed, as to decrease in geometrical progression, at altitudes which rise only in arithmetical progression; by which it happens, that the altitudes ascended are proportional only to the logarithms of the decrease of density there. Hence it results, that the balls must be always less and less resisted in their ascent, with the same velocity, and that they must consequently rise to greater heights before they stop. It is now therefore to be considered what may be the difference resulting from this circumstance.

Now, the nature and measure of this decreasing density of ascents in the atmosphere, has been explained and determined in prop. 76, p. 244, &c. vol. 2. It is there shown, that if  $D$  denote the air's density at the earth's surface, and  $d$  its density at any altitude  $a$ , or  $x$ ; then is  $x = 63551 \times$

log. of  $\frac{D}{d}$  in feet, when the temperature of the air is  $55^\circ$ ; and  $60000 \times \log. \frac{D}{d}$  for the temperature of freezing cold; we may therefore assume for the medium  $x = 62000 \times \log. \frac{D}{d}$  for a mean degree between the two.

But to get an expression for the density  $d$ , in terms of  $x$ , out of logarithms, without which it could not be introduced into the measure of the ball's resistance, in a manageable form, we find in the first place, by a neat approximate expression

for the natural number to the log. of a ratio,  $\frac{D}{d}$ ,

whose terms do not greatly differ, invented by Dr. Halley, and explained in the Introduction to Dr.

Hutton's Logarithms, p. 110, that  $\frac{n - \frac{1}{2}l}{n + \frac{1}{2}l} \times D$  nearly,

is the number answering to the log.  $l$  of the ratio

$\frac{D}{d}$ , where  $n$  denotes the modulus .43429448, &c. of the common logarithms. But, we before found

that  $x = 62000 \times \log. \text{ of } \frac{D}{d}$ , or  $\frac{x}{62000}$  is the log. of

$\frac{D}{d}$ , which log. was denoted by  $l$  in the expression

just above, for the number whose log. is  $l$  or  $\frac{x}{62000}$ ;

substituting therefore  $\frac{x}{62000}$  for  $l$ , in the expres-

sion  $\frac{n - \frac{1}{2}l}{n + \frac{1}{2}l} \times D$ , it gives the natural number

# PROJECTILES.

$$\frac{n - \frac{x}{124000}}{n + \frac{x}{124000}} \times D = d, \text{ or } \frac{124000n - x}{124000n + x} = d, \text{ the den-}$$

sity of the air at the altitude  $x$ , putting  $D=1$  the density at the surface. Now put  $124000n$  or nearly  $54000=c$ ; then  $\frac{c-x}{c+x}$  will be the density of the air at any general height  $x$ .

But, in the 5th prob. it appears that  $av^2$  denotes the resistance to the velocity  $v$ , or at the height  $x$ , for the density of air the same as at the surface, which is too great in the ratio of  $c+x$  to  $c-x$ ;

therefore  $av^2 \times \frac{c-x}{c+x}$  will be the resistance at the

height  $x$ , to the velocity  $v$ , where  $a=.00025^4$ . To this adding  $w$ , the weight of the ball, gives  $av^2 \times$

$\frac{c-x}{c+x} + w$  for the whole resistance, both from the

air and the ball's mass; consequently  $\frac{av^2}{w} \times \frac{c-x}{c+x} +$

$\frac{w}{w}$  will denote the accelerating force of the ball.

Or, if we include the small part  $\frac{w}{w}$  or 1, within

the factor  $\frac{c-x}{c+x}$ , which will make no sensible dif-

ference in the result, but be a great deal simpler

in the process, then is  $\frac{av^2 + w}{w} \times \frac{c-x}{c+x} = f$  the

accelerating force. Conseq.  $-vv = 2gf\dot{x} = 2g\dot{x}$

$\times \frac{c-x}{c+x} \times \frac{av^2 + w}{w}$ , and hence  $\frac{c-x}{c+x} \dot{x} = \frac{w}{2g} \times$

$\frac{-vv}{av^2 + w}$ , or by division,  $-\dot{x} + \frac{2c}{c+x} \dot{x} = \frac{w}{32a} \times$

$\frac{-vv}{av^2 + w}$ .

$\dot{x}^2 + \frac{w}{a}$

Now the fluent of the first side of this equation

is evidently  $-x + 2c \times \text{h. l. } (c+x)$ ; and the fluent

of the latter side, the same as in prob. 5, is  $\frac{-w}{64a}$

$\times \text{h. l. } (v^2 + \frac{w}{a})$ ; therefore the general fluential

equa. is  $-x + 2c \times \text{h. l. } (c+x) = \frac{-w}{64a} \times \text{h. l.}$

$(v^2 + \frac{w}{a})$ . But, when  $x=0$ , and  $v=v$  the initial

velocity, this becomes  $0 + 2c \times \text{h. l. } c = \frac{-w}{64a} \times \text{h. l.}$

$(v^2 + \frac{w}{a})$ ; therefore, by subtraction, the correct

fluents are  $-x + 2c \times \text{h. l. } \frac{c+x}{c} = \frac{w}{64a} \times \text{hyp. log.}$

$\frac{av^2 + w}{av^2 + w}$ ; when the first velocity  $v$  is diminished

to any less one  $v$ ; and when it is quite extinct,

the state of the fluents becomes  $-x + 2c \times \text{h. l.}$

$\frac{c+x}{c} = \frac{w}{64a} \times \text{h. l. } \frac{av^2 + w}{w}$ , for the greatest

height  $x$  ascended.

Here, in the quantity  $\text{h. l. } \frac{c+x}{c}$ , the term  $x$  is

always small in respect of the other term  $c$ ; there-

fore, by the nature of logarithms, the h. l. of

$\frac{c+x}{c}$  is nearly  $= \frac{x}{c} \text{ or } \frac{2x}{2c+x}$ ; therefore, the

above fluents become  $-x + \frac{4c^2}{2c+x} = \frac{2c^2 - x^2}{2c+x}$

$\frac{2c-x}{2c+x} = \frac{w}{64a} \times \text{h. l. } \frac{av^2 + w}{w}$ . Now the latter

side of this equation is the same value for  $x$  as was

found in the 5th problem, which therefore put  $=b$ ;

then the value of  $x$  will be easily found from the

formula  $\frac{2c-x}{2c+x} = b$ , by a quadratic equation. Or,

still easier, and sufficiently near the truth, by sub-

stituting  $b$  for  $x$  in the numerator and the denomi-

nator of  $\frac{2c-x}{2c+x}$ , then  $\frac{2c-b}{2c+b} = b$ , and hence  $x =$

$\frac{2c+b}{2c-b} b$ , or by proportion, as  $2c-b : 2c+b :: b : x$ ;

that is, only increase the value of  $x$ , found by prob-

lem 5, in the ratio of  $2c-b$  to  $2c+b$ .

Now, in the first example to that prob. the

value of  $x$  or  $b$  was there found  $=2955$ ; and  $2c$

being  $=108000$ , therefore,  $2c-b = 105045$ , and

$2c+b = 110955$ , then as  $105045 : 110955 :: 2955 :$

$3121$  is the value of the height  $x$  in this case, be-

ing only 166 feet, or  $\frac{1}{13}$ th part more than before.

Also, for the 2d example to the 5th prob. where

$x$  was  $=6420$ ; therefore as  $2c-b : 2c+b$  or as

$105345 : 110955 :: 6420 : 6780$  the height as-

cended in this example, being also the 18th part

more than before. And so on, for any other ex-

amples; the value of  $2c$  being the constant num-

ber 108000.

PROB. VIII.—To determine the time of a ball's

ascending, considering the decreasing density of

the air, as in the last prob.

The fluxion of the time  $t = \frac{\dot{x}}{v}$ . But the gene-

ral equation of the fluxions of the space  $x$  and ve-

locity  $v$ , in the last prob. was  $\frac{c-x}{c+x} \dot{x} = \frac{w}{32} \times$

$\frac{-vv}{av^2 + w}$ ; ther.  $\dot{x} = \frac{w}{32} \times \frac{c+x}{c-x} \times \frac{-v}{av^2 + w}$ ; hence

$t \text{ or } \frac{\dot{x}}{v} = \frac{w}{32} \times \frac{c+x}{c-x} \times \frac{-v}{av^2 + w}$ . But  $x$ , which is

always small in respect of  $c$ , is nearly  $=b$  as

determined in the last problem; therefore  $\frac{c+b}{c-b}$

may be substituted for  $\frac{c+x}{c-x}$  without sensible er-

ror; and then  $t$  becomes  $= \frac{w}{32} \times \frac{c+b}{c-b} \times \frac{-v}{av^2 + w}$ .

Now, this fluxion being to that in prob. 6, in the

constant ratio of  $c-b$  to  $c+b$ , their fluents will be

also in the same constant ratio. But, by the last

prob.  $c=54000$ , and  $b=2955$  for the first exam-

ple in prob. 5; therefore  $c-b=51045$ , and  $c+b=$

$56955$ , also, the time in problem 6 was  $9^m 91^s$ ;

therefore as  $51045 : 56955 :: 9^m 91^s : 11^m 04^s$  for the

time in this case, being  $1^m 13^s$  more than the for-

mer, or nearly the 9th part more; which is nearly

the double, or as the square of the difference, in

the last prob. in the height ascended.

PROB. IX.—To determine the circumstances of

X X 2

# PROJECTILES.

space, time, and velocity, of a ball descending through the atmosphere by its own weight.

It is here meant that the balls are at least as heavy as cast iron, and therefore their loss of weight in the air insensible; and that their motion commences by their own gravity from a state of rest. The first object of enquiry may be, the utmost degree of velocity any such ball acquires by thus descending. Now it is manifest that the ball's motion is commenced, and uniformly increased, by its own weight, which is its constant urging force, being always the same, and producing an equal increase of velocity in equal times, excepting for the diminution of motion by the air's resistance. It is also evident that this resistance, beginning from nothing, continually increases, in some ratio, with the increasing velocity of the ball. Now, as the urging force is constantly the same, and the resisting force always increasing, it must happen that the latter will at length become equal to the former: when this happens, there can afterwards be no further acceleration of the motion, the impelling force and the resistance being equal, and the ball must ever after descend with a uniform motion. It follows therefore that, to answer the first enquiry, we have only to determine when or what velocity of the ball will cause a resistance just equal to its own weight.

Now, by inspecting the tables of resistances preceding prob. 1, particularly the 1st of the three tables, the weight of the ball being 1.05 lb. we perceive that the resistance increases in the 2d column, till 0.69 opposite to 200 velocity, and 1.56 answering to 300 velocity, between which two the proposed resistance 1.05, and the correspondent velocity, fall. But, in two velocities not greatly different, the resistances are very nearly proportional to the squares of the velocities. Therefore, having given the velocity 200 answering to the resistance 0.69, to find the velocity answering to the resistance 1.05, we must say, as 0.69 : 1.05 :: 200<sup>2</sup> : v<sup>2</sup> = 60870, therefore  $v = \sqrt{60870} = 246$ , is the greatest velocity this ball can acquire; after which it will descend with that velocity uniformly, or at least with a velocity nearly approaching to 246.

The same greatest or uniform velocity will also be directly found from the rule  $\cdot 00001725v^2 = r$ , near the end of problem 2, where  $r$  is the resistance to the velocity  $v$ , by making 1.05 =  $r$ ; for then  $v^2 = \frac{1.05}{\cdot 00001725} = 60870$ , the same value for  $v^2$  as before.

But now, for any other weight of ball; as the weights of the balls increase as the cubes of their diameters, and their resistances, being as the surfaces, increase only as the squares of the same, which is one power less; and the resistances being also in this case, as the squares of the velocities, we must therefore increase the squares of the velocity in the ratio of the diameters of the balls;

that is, as  $1.965 : d :: 246^2 : d^2$ , and hence  $v = 246 \sqrt{\frac{d}{1.965}} = 175\frac{1}{2} \sqrt{d}$ .

If we take here the 3 lb. ball, belonging to the 2d table of resistances, whose diameter  $d$  is = 2.80; then  $\sqrt{2.80} = 1.673$ , and  $175\frac{1}{2} \times 1.67 = 294$ , is the greatest or uniform velocity, with which the 3 lb. ball will descend. And if we take the 6 lb. ball, whose diameter is 3.53 inches, as in the 3d table of resistances: then  $\sqrt{3.53} = 1.88$ , and

$175\frac{1}{2} \times 1.88 = 330$ , being the greatest velocity that can be acquired by the 6 lb. ball, and with which it will afterwards uniformly descend. For a 9 lb. ball, whose diameter is 4.04, the velocity will be  $175\frac{1}{2} \times 2.01 = 353$ . And so on for any other size of iron ball, as in the following table.

| Wt. lbs. | Diam. inch. | Term. Veloc. feet. | Height due to $v$ , feet. |
|----------|-------------|--------------------|---------------------------|
| 1        | 1.94        | 244                | 930                       |
| 2        | 2.45        | 275                | 1182                      |
| 3        | 2.80        | 294                | 1260                      |
| 4        | 3.08        | 308                | 1482                      |
| 6        | 3.53        | 330                | 1701                      |
| 9        | 4.04        | 353                | 1958                      |
| 12       | 4.45        | 370                | 2139                      |
| 18       | 5.09        | 396                | 2450                      |
| 24       | 5.60        | 415                | 2691                      |
| 32       | 6.17        | 436                | 2970                      |
| 36       | 6.41        | 444                | 3080                      |
| 42       | 6.75        | 456                | 3249                      |

Where the first column contains the weight of the balls in lbs.; the 2d their diameters in inches; the 3d their velocities to which they nearly approach, as a limit, and therefore called their terminal or last velocities, with which they afterward descend uniformly; and the 4th or last column the heights due to those velocities, or the heights from which the balls must descend in vacuo to acquire them.

But it is manifest that the balls can never attain exactly to these velocities in any finite time or descent, being only the limits to which they continually approach, without ever really reaching, though they arrive very nearly at them in a short space of time; as will appear by the following calculation.

To obtain general expressions for the space descended, and the time of the descent, in terms of the velocity  $v$ : put  $x$  = any space descended,  $t$  = its time, and  $v$  the velocity acquired, the weight of the ball  $w = 1.05$  lb. Now, by the theorem near the end of prob. 2, which is the proper rule for this case, the velocity being small,  $\cdot 00001725v^2 = cv^2$  is the resistance due to the velocity  $v$ ; theref.  $w - cv^2$  is the impelling force, and

$$\frac{w - cv^2}{w} = f \text{ the accelerating force; consequently}$$

$$vv \text{ or } 2gf\dot{x} = 2g\dot{x} \times \frac{w - cv^2}{w}, \text{ and } \dot{x} = \frac{w}{2g} \times \frac{vv}{w - cv^2}, \text{ the}$$

correct fluent of which, by the 8th form, is  $x = \frac{w}{4g^c}$

$\times$  h. 1.  $\frac{w}{w - cv^2}$ , the general value of the space  $x$  descended.

Here it appears that the denominator  $w - cv^2$  decreases as  $v$  increases; conseq. the whole value of  $x$ , the descent, increases with  $v$ , till it becomes infinite, when the resistance  $cv^2$  is =  $w$  the weight of the ball, when the motion becomes uniform, as before remarked. We may, however, easily assign the value of  $x$  a little before the velocity becomes uniform, or before  $cv^2$  becomes =  $w$ . Thus, when  $cv^2 = w$ , then  $v = 246$ , as found in the beginning of this problem. Assume therefore  $v$  a little less than that greatest velocity, as for in-

# PROJECTILES.

stance 240: then this value of  $v$  substituted in the general formula for  $x$  above deduced, gives  $x = 2781$  feet, a little before the motion becomes uniform, or when the velocity has arrived at 240, its maximum being 246.

In like manner is the space to be computed that will be due to any other velocity less than the greatest or terminal velocity. On the contrary, to find the velocity due to any proposed space  $x$ ,

from the formula  $x = \frac{w}{4g^c} \times \text{h. l.} \frac{v}{w - cv^2}$ . Here

$x$  is given to find  $v$ . First then  $\frac{4g^c x}{w} = \text{h. l.}$

$\frac{v}{w - cv^2}$ : take therefore the number to the hyp.

log. of  $\frac{4g^c x}{w}$ , which number call  $N$ ; then  $N =$

$\frac{w}{w - cv^2}$ ; consequently  $Nw - Ncv^2 = w$ , and  $Nw -$

$w = Ncv^2$ , and  $v = \sqrt{\frac{N - I}{NC}} w$ , a general theorem

for the value of  $v$  due to any distance  $x$ . Suppose, for instance,  $x$  is 1000. Now  $4g$  being

$= 64$ ,  $w = 1.05$ , and  $c = .00001725$ ; therf.  $\frac{4g^c x}{w}$

$= 1.0514$ , and the natural number belonging to this, considered as an hyp. log. is  $2.8617 = N$ ;

hence then  $v = \sqrt{\frac{N - I}{NC}} w = 199$ , is the velocity

due to the space 1000, or when the ball has descended 1000 feet.

Again, for the time  $t$  of descent: here  $t = \frac{x}{v}$ ;

but  $x = \frac{w}{2g} \times \frac{v}{w - cv^2}$ , as found above, therefore

$t = \frac{w}{2g} \times \frac{v}{w - cv^2}$ , the fluent of which is  $\frac{I}{4g^c} \sqrt{\frac{w}{c}}$

$\times \text{h. l.} \frac{w + v}{\frac{w}{c} - v}$ , the general value of the time  $t$

for any value of the velocity  $v$ ; which value of  $t$

evidently increases as the denominator  $\sqrt{\frac{w}{c} - v}$

decreases, or as the velocity  $v$  increases; and consequently the time is infinite when that denominator vanishes, which is when  $v = \sqrt{\frac{w}{c}}$ , or  $cv^2 = w$ ,

the resistance equal to the ball's weight, being the same case as when the space  $x$  becomes infinite, as above remarked. But, like as was done for the distance  $x$  as above, we may here also find the value of  $t$  corresponding to any value of  $v$ , less than its maximum 246, and consequently to any value of  $x$ , as when  $v$  is 240 for instance, or  $x = 2781$ , as determined above. Now, by substituting

240 for  $v$ , in the general formula  $t = \frac{I}{4g} \sqrt{\frac{w}{c}} \times \text{h. l.}$

$\frac{w + v}{\frac{w}{c} - v}$ , it brings out  $t = 16.575$ ; so that it

would be nearly  $16\frac{1}{2}$  seconds when the velocity arrives at 240, or a little less than the maximum

or uniform degree, viz. 246, or when the space descended is 2781 feet.

Also, to determine the time corresponding to the same, or when the descent is 1000 feet, or

the velocity 199: find the value of  $\frac{I}{4g} \sqrt{\frac{w}{c}} = \frac{I}{64}$

$\sqrt{\frac{1.05}{.00001725}} = \frac{246}{64} = \frac{123}{32}$ . Then

$\frac{v}{\frac{w}{c} - v} = \frac{246 + 199}{249 - 199} = \frac{445}{47}$ ; the hyp. log. of

which is  $2.2479$ . Hence  $2.2479 \times \frac{123}{32} = 8.64$ ,

the time of descending 1000 feet, or when the velocity is 199.

PROB. X.—To determine the circumstances of the motion of a ball projected horizontally in the air; abstracted from its vertical descent by its gravitation.

Putting  $d$  for the diameter, and  $w$  the weight of the ball,  $v$  the velocity of projection, and  $v$  the velocity of the ball after having moved through the space  $x$ . Then, by corol. 1 to prob. 2, if the velocity is considerable, such as usual in practice, the resistance of the ball, moving with the velocity  $v$ , is  $(mv^2 - nv)d^2$ , and therefore  $\frac{mv^2 - nv}{w}d^2$

is the retardive force  $f$ ; hence the common formula  $vv = 2gfs$ , is  $-vv = 32x \times \frac{mv^2 - nv}{w}d^2$ , and there-

fore  $x = \frac{w}{32d^2} \times \frac{-vv}{mv^2 - nv} = \frac{w}{32d^2} \times \frac{-v}{mv - n} = \frac{w}{32d^2m}$

$\times \frac{-v}{v - m}$ , the fluent of which is obviously  $\frac{w}{32md^2}$

$\times$  hyp. log. of  $v - \frac{n}{m}$ , and by the correction

by the first velocity  $v$ , it becomes  $x = \frac{w}{32md^2} \times$

hyp. log.  $\frac{v - \frac{n}{m}}{v - m}$ , the general formula for the dis-

tance passed over in terms of the velocity.

Now, for an application, let it be required first, to determine in what space a 24 lb. ball will have its velocity reduced from 1780 feet to 1500, that is, losing 280 feet of its first velocity. Here,  $d = 5.6$ ,

$w = 24$ ,  $v = 1780$ , and  $v = 1500$ ; also  $\frac{n}{m} = 150$ .

Hence  $\frac{w}{32md^2} = 3587.4$ , then  $x = 3587.4 \times \text{h. l.}$

$\frac{v - 150}{v - 150} = 3587.4 \times \text{h. l.} \frac{1630}{1350} = 3587.4 \times \text{h. l.}$

$\frac{163}{135} = 676$  feet, the space passed over when the

ball has lost 280 feet of its motion.

Again, to find with what velocity the same ball will move, after having described 1000 feet in its flight. The above theorem is  $x$  or  $1000 = 3587.4$

$\times \text{h. l.} \frac{v - 150}{v - 150} = 3587.4 \times \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

$\frac{1000}{3587.4} = \text{h. l.} \frac{1630}{v - 150}$ , or

# PROJECTILES.

= h. l.  $\frac{1630}{v-150}$ ; but the number to the hyp. log.

$\frac{10000}{35374}$  is  $1.7416 = N$  suppose; then  $N = \frac{1630}{v-150}$ ,

and  $Nv - 150N = 1630$ , or  $Nv = 1630 + 150N$ , and

$v = \frac{1630}{N} - 150 = 936 - 150 = 786$ , the velocity

when the ball has moved 1000 feet.

Next, to find a theor. for the time of describing any space, or destroying any velocity: here  $\dot{x} =$

$\frac{\dot{x}}{v} = \frac{w}{32nd^2} \times \frac{v-n}{v-\frac{n}{m}}$  the fluent of which, by

the 9th form, is  $t = \frac{w}{32nd^2} \times \frac{m}{n} \times \text{h. l. } \frac{v}{v-\frac{n}{m}}$

$= \frac{w}{32nd^2} \times \text{hyp. log. } \frac{v}{v-\frac{n}{m}}$ , and by correction

$t = \frac{w}{32nd^2} \times (\text{h. l. } \frac{v}{v-\frac{n}{m}} - \text{h. l. } \frac{v}{v-\frac{n}{m}}) = \frac{w}{32nd^2} \times$

$\text{hyp. log. } \frac{v-150}{v-150} \cdot \frac{v}{v}$ , putting  $v$  for the first velocity, and 150 for  $\frac{n}{m}$  its value, as before.

Now, to take for an example the same 24 lb. ball, and its projected velocity 1780, as before; let it be required to find in what time this velocity will be reduced to 786. Here then  $v = 1780$ ,  $v = 786$ ,  $w = 24$ ,  $d = 5.6$ ,  $d^2 = 31.36$ ,  $n = .001$ ; hence

$\frac{w}{32nd^2} = \frac{750}{31.36} = 23.916$ ; and  $\frac{v-150}{v-150} \cdot \frac{v}{v} = \frac{1630}{630}$

$\times \frac{786}{1780} = \frac{21353}{18368}$ , the hyp. log. of which is .1099; then  $31.36 \times .1099 = 2.628$ , the time required.

For another example, let it be required to find when the velocity will be reduced to 1000, or 780 destroyed. Here  $v = 1000$ , and all the other quantities as before. Then  $\frac{v-150}{v-150} \times \frac{v}{v} = \frac{1630}{850}$

$\times \frac{1000}{1780} = \frac{1630}{1513}$ , the hyp. log. of which is .07449; therefore  $31.36 \times .07449 = 1.78$ , is the time sought.

On the other hand if it be required to find what will be the velocity after the ball has been in motion during any given time, as suppose two seconds, we must reverse the calculation thus:

$t = 2$  being  $\frac{w}{32nd^2} \times \text{hyp. log. } \frac{v-150}{v-150} \cdot \frac{v}{v} =$

$23.916 \times \text{hyp. log. } \frac{v-150}{v-150} \cdot \frac{v}{v}$ ; theref.  $23.916$

$= .08356$  is the hyp. log. of  $\frac{v-150}{v-150} \cdot \frac{v}{v}$ , the

number answering to which is  $1.08725 = N$  sup-

pose, that is,  $N = \frac{v-150}{v-150} \cdot \frac{v}{v}$ . Hence  $Nv - 150N =$

$150Nv = v^2 - 150v$ , and  $v = \frac{150Nv}{150 + Nv - v}$

$\frac{290290}{305305} = 951$ , the velocity at the end of two seconds.

The foregoing calculations serve only for the higher velocities, such as exceed 200 or 300 feet per second of time. But, for those that are below 300, the rule is simpler, as the resistance is then, by cor. 2. prob. 2.  $.00000447d^2v^2 = cd^2v^2$ , where  $d$  denotes the diameter of any ball. Hence

then, employing the same notation as before,  $\frac{cd^2v^2}{w}$

$= f$ , and  $-v\dot{v} = 32fx = 32x \times \frac{cd^2v^2}{w}$ ; theref.  $\dot{x} =$

$\frac{w}{32cd^2} \times \frac{v}{v}$ , the correct fluent of which is  $x =$

$\frac{w}{32cd^2} \times \text{hyp. log. } \frac{v}{v}$ .

Now, for an example, suppose the first velocity to be 300 =  $v$ , and the last  $v = 100$ , for a 24 lb. ball. Then  $w = 24$ ,  $d = 5.6$ ,  $d^2 = 31.36$ ,  $c =$

$.00000447$ ; therefore  $\frac{w}{32cd^2} = \frac{3}{125.446} = 5350$ ;

and  $\frac{v}{v} = \frac{300}{100} = 3$ , the hyp. log. of which is .10986; therefore  $.10986 \times 5350 = 5878 = x$ , is the distance. If the first velocity be only 200

$= v$ ; then  $\frac{v}{v} = 2$ , the h. l. of which is .69315,

therefore  $.69315 \times 5350 = 3708 = x$ , the distance.

And conversely, to find what velocity will remain after passing over any space, as 4000 feet, the first velocity being  $v = 200$ . Here the hyp.

log. of  $\frac{v}{v}$  is  $\frac{x}{5350} = \frac{4000}{5350} = \frac{400}{535} = \frac{80}{107} =$

.74766, the natural number of which is 2.1120,

that is,  $2.112 = \frac{v}{v}$ ; therefore  $v = \frac{200}{2.112} =$

947, the velocity.

Again, for the time  $t$ : since  $\dot{x} = \frac{w}{32cd^2} \times \frac{v}{v}$ ,

therefore  $t = \frac{\dot{x}}{v} = \frac{w}{32cd^2} \times \frac{v}{v^2}$ , the correct flu-

ent of which is

$t = \frac{w}{32cd^2} \times (\frac{1}{v} - \frac{1}{v}) = \frac{w}{32cd^2} \times \frac{v-v}{vv}$ . So,

for example, if  $v = 300$ , and  $v = 100$ , then  $\frac{v-v}{vv} =$

$= \frac{200}{30000} = \frac{2}{300}$ ; then  $\frac{w}{32cd^2}$  or  $5350 \times \frac{2}{300}$

$= 35.66 = t$ , the time of reducing the 300 velocity to 100, or of passing over the space 5878 feet.

And reversing, to find the velocity  $v$ , answering to any given time  $t$ : Since

$t = \frac{w}{32cd^2} \times (\frac{1}{v} - \frac{1}{v}) = 5350 \times (\frac{1}{v} - \frac{1}{v})$ ,

therefore  $v = \frac{5350}{5350 + tv}$ . Here, if  $t$  be given

# PROJECTILES.

$= 30''$ , and  $v = 300$ ; then  $v = \frac{5350v}{5350 + 9000}$   
 $= \frac{535}{1435} \times 300 = \frac{32100}{287} = 112$ , the velocity sought.

Corol. The same form of theorem,  $x = \frac{v}{3200a^2}$

$\times \text{hyp. log. } \frac{v}{v}$ , as above, is brought out for small velocities, will also serve for the higher ones, if we employ the medium resistance between the two proposed velocities, as was done in prob. 5. Thus, as in the first example of this problem, where the two velocities are 1780 and 1500, the resistance due to the velocity 1700, in the first table of resistances, being 74.13, say as 1700<sup>2</sup> : 1780<sup>2</sup> :: 74.13 : 81.27, the resistance due to the velocity 1780; then the mean between 81.27 and 57.25, due to 1500 velocity, is 69.26, or rather take 69½. Again, as  $\sqrt{65.7} : \sqrt{69.5} :: 1690 : 1646$ , the velocity due to the medium resistance 69½. Hence, as in prob. 5, as 1646<sup>2</sup> : v<sup>2</sup> :: 69½ : .00002565v<sup>2</sup> = suppose av<sup>2</sup>, the resistance due to any velocity v, between 1780 and 1500, for the 1.05 lb. ball. And, as 1965<sup>2</sup> : 5.6<sup>2</sup> :: av<sup>2</sup> : 8.124av<sup>2</sup> = .0002038v<sup>2</sup> = bv<sup>2</sup> suppose, the resistance due to the same velocity with the 24 lb. ball.

Therefore  $\frac{bv^2}{24} = f$ , and  $-vv = 32f \dot{x} = \frac{4}{3}bv^2 \dot{x}$ , and  $\dot{x} =$

$-\frac{3v}{4bv}$ , the correct fluent of which is  $\frac{3}{4b} \times \text{hyp. log.}$

$$\frac{v}{v} = \frac{3}{4b} \times \text{hyp. log. } \frac{178}{150} = \frac{3}{4b} \times \text{hyp. log.}$$

$$\frac{89}{75} = 3600 \times .171148 = 616 \text{ the velocity sought.}$$

PROB. XI.—To determine the ranges of projectiles in the air.

To determine, by theory, the trajectory a projectile describes in the air, is one of the most difficult problems in the whole course of dynamics, even when assisted by all the experiments that have hitherto been made on this branch of physics; and is indeed much too difficult for this place, in the full extent of the problem: the consideration of it must therefore be reserved for another occasion, when the nature of the air's resistance may be more amply discussed. Even the solutions of Newton, of Bernoulli, of Euler, of Borda, &c. &c. after the most elaborate investigations, assisted by all the resources of the modern analysis, amount to no more than distant approximations, that are rendered nearly useless, even to the speculative philosopher, from the assumption of a very erroneous law of resistance in the air, and much more so to the practical artilleryman, both on that account, and from the very intricate process of calculation, which is quite inapplicable to actual service. The solution of

this problem requires, as an indispensable datum, the perfect determination, by experiment, of the nature and laws of the air's resistance at different altitudes, to balls of different sizes and densities, moving with all the usual degrees of celerity.

All that can be here done then, in the solution of the present problem, besides what is delivered in the 2d volume, is to collect together some of the best practical rules, founded partly on theory, and partly on practice. 1. In the first place then, it may be remarked, that the initial or first velocity of a ball may be directly computed by problem 17, near the end of the 2d volume; having given the dimensions of the piece, the weight of the ball, and the charge of powder. Or otherwise, the same may be made out from the table of experimented ranges and velocities in p. 161 of that volume, by this rule, that the velocities to different balls, and different charges of powder, are as the square roots of the weights of the powder directly, and as the square roots of the weights of the balls inversely. Thus, if it be enquired with what velocity a 24 lb. ball will be discharged by 8 lb. of powder. Now it appears in the table, that 8 ounces of powder discharge the 1 lb. ball with 1640 feet velocity; and because 8 lb. are = 128 ounces; therefore by the rule, as  $\sqrt{8} : \sqrt{128} :: 1640 : 1640\sqrt{\frac{16}{24}} = 1640\sqrt{\frac{2}{3}} = 1339$ , the velocity sought. Or otherwise, by rule I, p. 162, of the 2d vol. as  $\sqrt{24} : \sqrt{16} :: 1600 : 1306$ , the same velocity nearly. But when the charges bear the same ratio to one another, as the weight of the balls, that is when the pieces are said to be alike charged, then the velocities will be equal. Thus, the 1 lb. ball by the 2 oz. charge, being the 8th part of the weight, and the 24 lb. ball, with 3 lb. of powder, its 8th part also, will have the same velocity, viz. 860 feet. In like manner, the 1230 tabular velocity, answering to 4 oz. of powder, the 4th part of the ball, will equally belong to the 24 lb ball with 6 lb. of powder, being its 4th part, and the tabular velocity 1640, answering to the 8 oz. charge, which is  $\frac{1}{2}$  the weight of ball, will equally belong to the 24 lb. ball with 12 lb. of powder, being also the  $\frac{1}{2}$  of its weight.

2. By prob. 9 will be found what is called the terminal velocity, that is, the greatest velocity a ball can acquire by descending in the air; indeed a table is there given of the several terminal velocities belonging to the different balls, with the heights, in an annexed column, due to those velocities in vacuo, that is the heights from which a body must fall in vacuo, to acquire those velocities.

3. Given the initial velocity, to find the elevation of the piece to have the greatest range, and the extent of that range. These will be found by means of the following table, altered from professor's Robson's, in the Encyclopædia Britannica, and founded on an approximation of sir I. Newton's. The numbers in the first column, multiplied by the terminal velocity of the ball, give the initial velocity; and the numbers in the last column, being multiplied by the height, give the greatest ranges; the middle column showing the elevations to produce those ranges.

| 2.4655                                         | 38 45     | 1.7472              |
| 2.7190                                         | 38 0      | 1.9409              |
| 2.9725                                         | 37 15     | 2.1346              |
| 3.2260                                         | 36 30     | 2.3283              |
| 3.4795                                         | 35 45     | 2.5220              |
| 3.7330                                         | 35 0      | 2.7157              |
| 3.9865                                         | 34 15     | 2.9094              |
| 4.2400                                         | 33 30     | 3.1031              |
| 4.4935                                         | 32 45     | 3.2968              |
| 4.7470                                         | 32 0      | 3.4905              |
| 5.0000                                         | 31 15     | 3.6842              |

To use this table then, divide the given initial velocity by the terminal velocity peculiar to the ball, found in the table in prob. 9, and look for the quotient in the first column here annexed. Against this, in the 2d column will be found the elevation to give the greatest range; and the number in the 3d column multiplied by *a*, the altitude due to the terminal velocity, also found

in the table in problem 9, will give the range, nearly.

*Exam. 1.* Let it be required to find the greatest range of a 24lb. ball, when discharged with 1640 feet velocity, and the corresponding angle to produce that range. By the table in prob. 9, the terminal velocity of the 24lb. ball is 415, and its

producing altitude 2691: hence  $\frac{1640}{415} = 3.95$ , nearly

equal to 3.9865 in the first column of our table, to which corresponds the angle 34° 15', being the elevation to produce the greatest range; and the corresponding number 2.9094, in the 3d column, multiplied by 2691, gives 7829 feet, for the greatest range, being nearly a mile and a half.

*Exam. 2.* In like manner, the same ball discharged with the velocity 860 feet, will have for its greatest range 3891 feet, or nearly  $\frac{3}{4}$  of a mile, and the elevation producing it 39° 55'.

These examples, and indeed the whole table in the 9th problem, are only adapted to the use of cannon balls. But it is not usual, and indeed not easily practicable, to discharge cannon shot at such elevations, in the British service, that practice being the peculiar office of mortar shells. On this account then it will be necessary to make out a table of terminal velocities, and altitudes due to them, for the different sizes of such shells. The several kinds of these in present use are denominated from the diameters of their mortar bores in inches, being the five following. viz. the 4, 6, the 5, 8, the 8, the 10, and the 13 inch mortars, as in the first column of the following table. But the outer diameters of the shell are somewhat smaller, to leave a little room or space as windage, as contained in the 2d column.

| Table of dimensions, &c. of mortar shells. |                  |                          |                        |                          |                    |                               |
|--------------------------------------------|------------------|--------------------------|------------------------|--------------------------|--------------------|-------------------------------|
| Diam. of mortar.                           | Diam. of shells. | Weight of shells filled. | Weight of equal solid. | Ratio of shell to solid. | Terminal velocity. | Alt. <i>a</i> . due to veloc. |
| inch.                                      | inch.            | lbs.                     | lbs.                   |                          | feet.              | f. et.                        |
| 4.6                                        | 4.53             | 9                        | 12 $\frac{3}{4}$       | 1.42                     | 314                | 1541                          |
| 5.8                                        | 5.72             | 18                       | 25 $\frac{1}{2}$       | 1.42                     | 352                | 1936                          |
| 8                                          | 7.90             | 47                       | 67                     | 1.42                     | 414                | 2678                          |
| 10                                         | 9.84             | 91 $\frac{1}{2}$         | 130                    | 1.42                     | 462                | 3335                          |
| 13                                         | 12.80            | 201                      | 286                    | 1.42                     | 527                | 4340                          |

The 3d column contains the weight of each shell when the hollow part is filled with powder: the diameter of the hollow is usually  $\frac{7}{8}$  of that of the mortar. The weight of the shells empty, and when filled, with other circumstances, may be seen at quest 53, p. 265, vol. 2. On account of the vacuity of the shell being filled only with gunpowder, the weight of the whole so filled, and contained in column 3, is much less than the weight of the same size of solid iron, and the corresponding weights of such equal solid balls are contained in col. 4. The ratio of these weights, or the latter divided by the former, occupies the 5th column.

Now, because the loaded or filled shells are of less specific gravity, or less heavy, than the equal solid iron balls, in the ratio of 1 to 1.42, as in column 5, the former will have less power or force to oppose the resistance of the air, in that same proportion, and the terminal or greatest velocity, as determined in the 9th problem; will be correspondently less. Therefore, instead of

the rule there given, viz.  $175.5\sqrt{d}$ , for that ve-

locity, the rule must now be  $175.5\sqrt{\frac{d}{1.42}} = 147.3$

$\sqrt{d} = v$ , the diameter of the shell being *d*; that is, the terminal velocities will be all less in the ratio of 147.3 to 175.5. Now, computing these several velocities by this rule, to all the different diameters, they are found as placed in the 6th column; and in the 7th or last column are set the altitudes which would produce these velocities

in vacuo, as computed from this theorem  $\frac{vv}{64}$ .

Having now obtained these terminal velocities, and their producing altitudes, for the shells, we can, from them and the former table of ranges and elevations, easily compute the greatest range, and the corresponding angle of elevation, for any mortar and shell, in the same way as was done for the balls in this problem. Thus, for example, to find the greatest range and elevation for the 13 inch shell, when projected with the velocity

of 2000 feet per second, being nearly the greatest velocity that balls can be discharged with. Now, by the method before used,  $\frac{2000}{527} = 3.796$ ; oppo-

site to this, found in the first column of the table of ranges, corresponds  $34^{\circ} 49'$  for the elevation in the 2d column, and the number 2.764 in the 3d column; this multiplied by the altitude 4340, gives 11995 feet, or more than  $2\frac{1}{2}$  miles, for the greatest range.

This however is much short of the distance which it is said the French have lately thrown some shells at the siege of Cadiz. viz. 3 miles, which it seems has been effected by means of a peculiar piece of ordnance and by loading or filling the cavity of the shell with lead, to render it heavier, and thus make it fitter to overcome the resistance of the air. Let us then examine what will be the greatest range of our 13 inch shell, if its usual cavity be quite filled with lead when discharged with the projectile velocity of 2000 feet.

Now the diameter of the cavity, being about  $\frac{7}{10}$  of that of the mortar 13, will be nearly 9 inches. And the weight of a globe of lead of this diameter is 139 3lb.; which added to 187.8, the weight of the shell empty, gives 327 lb. the whole weight of the shell when the cavity is filled with lead, which was found 286 when supposed all of solid iron, their ratio or quotient is .8783. Then,

as before, the theorem will be  $175.5\sqrt{\frac{d}{.8783}} = 1873\sqrt{d}$  for the terminal velocity; which, when  $d=12.8$ , becomes 670 for the terminal velocity;

therefore its producing altitude is  $\frac{670^2}{64} = 7014$ .

Then, by the same method as before,  $\frac{2000}{670} =$

2.985; which number, found in the first column of the table of ranges, the opposite number in the 2d col. is  $37^{\circ} 15'$  for the elevation of the piece, and in the 3d column 2.14, multiplied by 7014, gives 15010 feet, or nearly 3 miles. So that our 13 inch shells, discharged at an elevation of about  $37\frac{1}{2}$  degrees, would range nearly the distance mentioned by the French, when filled with lead, if they can be projected with so much as 2000 feet velocity, or upwards. This however it is thought cannot possibly be effected by our mortars; and that it is therefore probable the French, to give such a velocity to those shells, must have contrived some new kind of large cannon on the occasion.

4. Having shown in the preceding articles and problems, how, from our theory of the air's resistance, can be found, first the initial or projectile velocity of shot and shells; 2dly, the terminal velocity, or the greatest velocity a ball can acquire by descending by its own weight in the air; 3dly, the height a ball will ascend to in the air, being projected vertically with a given velocity, also the time of that ascent; 4thly, the greatest horizontal ranges of given shot, projected with a given velocity; as also the particular angle of elevation of the piece, to produce that greatest range. It remains then now to enquire, what laws and regulations can be given respecting the ranges, and times of flight, of projects made at other angles of elevation.

Relating to this enquiry, the Encyclopædia Britannica mentions the two following rules:

1st, "Balls of equal density, projected with the same elevation, and with velocities which are as the square roots of their diameters, will describe similar curves. This is evident, because, in this case, the resistance will be in the ratio of their quantities of motion; therefore all the homologous lines of the motion will be in the proportion of the diameters." But though this may be nearly correct, yet it can hardly ever be of any use in practice, since it is usual and proper to project small balls, not with a less, but with a greater velocity, than the larger ones. 2dly, the other rule is, "If the initial velocities of balls, projected with the same elevation, be in the inverse subduplicate ratio of the whole resistances, the ranges, and all the homologous lines in their track, will be inversely as those resistances." This rule will come to the same thing, as having the initial velocities in the inverse ratio of the diameters, as distant perhaps from fitness as the former. Two tables are next given in the same place, for the comparison of ranges and projectile velocities, the numbers in which appear to be much wide of the truth, as depending on very erroneous effects of the resistance. Most of the accompanying remarks, however, are very ingenious, judicious, and philosophical, and very justly recommending the making and recording of good experiments on the ranges and times of flight of projects, of various sizes, made with different velocities, and at various angles of elevation.

Besides the above, we find rules laid down by Mr. Robins and Mr. Simpson, for computing the circumstances relating to projectiles as affected by the resistance of the air. Those of the former respectable author, in his ingenious *Tracts on Gunnery*, being founded on a quantity which he calls  $r$  (answering to our letter  $a$  in the foregoing pages), almost uniformly double of what it ought to be, owing to his improper measures of the air's resistance; and therefore the conclusions derived by means of those rules must needs be very erroneous. Those of the very ingenious Mr. Simpson, contained in his *Select Exercises*, being partly founded on experiment, may bring out conclusions in some of the cases not very incorrect; while some of them, particularly those relating to the impetus and the time of flight, must be very wide of the truth. We must therefore refer the student, for more satisfaction, to the rules and examples given by Dr. Hutton in vol. 2, p. 162, &c. Course of Mathematics, especially for the circumstances of different ranges and elevations, &c. after having determined, as above, those for the greatest ranges, founded on the real measure of the resistances.

PROJECTION. *s.* (from *project.*) 1. The act of shooting forward (*Brown*). 2. (*projection*, French.) Plan; delineation (*Watts*). 3. Scheme; plan of action. 4. In chemistry, crisis of an operation (*Bacon*).

PROJECTION, in mechanics, the act of giving a projectile its motion.

If the direction of the force, by which the projectile is put in motion, is perpendicular to the horizon, the projection is said to be perpendicular; if parallel to the apparent horizon, it is said to be an horizontal projection; and if it makes an oblique angle with the horizon, the projection is oblique. In all cases, the angle which the line of direction makes with the ho-

# PROJECTION.

horizontal line, is called the angle of elevation of the projectile, or of depression when the line of direction points below the horizontal line.

**PROJECTION**, in perspective, denotes the appearance or representation of an object on the perspective plane. So, the projection of a point, is a point where the optic ray passes from the objective point through the plane to the eye; or it is the point where the plane cuts the optic ray. And hence it is easy to conceive what is meant by the projection of a line, a plane, or a solid.

**PROJECTION OF THE SPHERE IN PLANO**, is a representation of the several points or places of the surface of the sphere, and of the circles described upon it, upon a transparent plane placed between the eye and the sphere, or such as they appear to the eye placed at a given distance. For the laws of this projection, see **PERSPECTIVE**; the projection of the sphere being only a particular case of perspective.

The chief use of the projection of the sphere, is in the construction of planispheres, maps, and charts; which are said to be of this or that projection, according to the several situations of the eye, and the perspective plane, with regard to the meridians, parallels, and other points or places to be represented.

The most usual projection of maps of the world, is that on the plane of the meridian, which exhibits a right sphere; the first meridian being the horizon. The next is that on the plane of the equator, which has the pole in the centre, and the meridians the radii of a circle, &c. and this represents a parallel sphere. See **MAP**.

The projection of the sphere is usually divided into orthographic and stereographic; to which may be added gnomonic.

**PROJECTION (Orthographic)**, is that in which the surface of the sphere is drawn upon a plane cutting it in the middle; the eye being placed at an infinite distance vertically to one of the hemispheres. And,

**PROJECTION (Stereographic)**, of the sphere, is that in which the surface and circles of the sphere are drawn upon the plane of a great circle, the eye being in the pole of that circle.

**PROJECTION (Gnomonical)** of the sphere, is that in which the surface of the sphere is drawn upon a plane without side of it, commonly touching it, the eye being at the centre of the sphere. See **DIALLING**.

*Laws of the orthographic projection.*—1. The rays coming from the eye, being at an infinite distance, and making the projection, are parallel to each other, and perpendicular to the plane of projection.

2. A right line perpendicular to the plane of projection, is projected into a point where that line meets the said plane. Fig. 2. pl. 146.

3. A right plane, as AB, or CD, not perpendicular, but either parallel or oblique to the plane of the projection, is projected into a right line, as EF or GH, and is always comprehended between the extreme perpendiculars AE and BF, or CG and DH.

4. The projection of the right line AB is the greatest, when AB is parallel to the plane of the projection.

5. Hence it is evident, that a line parallel to the plane of the projection, is projected into a right line equal to itself; but a line that is oblique to the plane of projection, is projected into one that is less than itself. Fig. 5.

6. A plane surface, as ACBD, perpendicular to the plane of the projection, is projected into the right line, as AB, in which it cuts that plane. Hence it is evident, that the circle ACBD perpendicular to the plane of projection, passing through its centre, is projected into that diameter AB in which it cuts the plane of the projection. Also any arch as Cc is projected into Oo, equal to ca, the right sine of that arch; and the complementary arc cB is projected into oB, the versed sine of the same arc cB.

7. A circle parallel to the plane of the projection, is projected into a circle equal to itself, having its centre the same with the centre of the projection, and its radius equal to the cosine of its distance from the plane. And a circle-oblique to the plane of the projection, is projected into an ellipsis, whose greater axis is equal to the diameter of the circle, and its less axis equal to double the cosine of the obliquity of the circle to a radius equal to half the greater axis.

*Properties of the stereographic projection.*—

1. In this projection a right circle, or one perpendicular to the plane of projection, and passing through the eye, is projected into a line of half-tangents.

2. The projections of all other circles, not passing through the projecting point, whether parallel or oblique, are projected into circles. Figs. 1, 3, 7.

Thus, let ACEDB represent a sphere, cut by a plane RS, passing through the centre I, perpendicular to the diameter EH, drawn from E the place of the eye; and let the section of the sphere by the plane RS be the circle CFDL, whose poles are H and E. Suppose now AGB is a circle on the sphere to be projected, whose pole most remote from the eye is P; and the visual rays from the circle HGB meeting in E, form the cone AGBE, of which the triangle AEB is a section through the vertex E, and diameter of the base AB, then will the figure agbf, which is the projection of the circle AGB, be itself a circle. Hence, the middle of the projected diameter is the centre of the projected circle, whether it is a great circle or a small one: also the poles and centres of all circles parallel to the plane of projection, fall in the centre of the projection: and all oblique great circles cut the primitive circle in two points diametrically opposite.

3. The projected diameter of any circle subtends an angle at the eye equal to the distance of that circle from its nearest pole, taken on the sphere; and that angle is bisected by a right line joining the eye and that pole. Thus, let the plane RS (fig. 4.) cut the sphere HFEC through its centre I; and let ABC be any

Mathew & Piffell 1852

oblique great circle, whose diameter AC is projected into *ac*; and KOL any small circle parallel to ABC, whose diameter KL is projected in *kl*. The distances of those circles from their pole P, being the arcs AHP, KHP, and the angles *aEc*, *kEl*, are the angles at the eye, subtended by their projected diameters, *ac* and *kl*. Then is the angle *aEc* measured by the arc AHP, and the angle *kEl* measured by the arc KHP; and those angles are bisected by EP.

3. Any point of a sphere is projected at such a distance from the centre of projection, as is equal to the tangent of half the arc intercepted between that point and the pole opposite to the eye, the semidiameter of the sphere being radius. Thus, let C<sub>1</sub>EB (fig. 8.) be a great circle of the sphere, whose centre is *c*; GH the plane of projection cutting the diameter of the sphere in *b* and B; also E and C the poles of the section by that plane; and *a* the projection of A. Then *ca* is equal to the tangent of half the arc AC, as is evident by drawing CF = the tangent of half that arc, and joining cF.

4. The angle made by two projected circles, is equal to the angle which these circles make on the sphere. For let IACE (fig. 6.) and ABL be two circles on a sphere intersecting in A; E the projecting point; and RS the plane of projection, in which the point A is projected in *a*, in the line IC, the diameter of the circle ACE. Also let DH and FA be tangents to the circles ACE and ABL. Then will the projected angle *daf* be equal to the spherical angle BAC.

5. The distance between the poles of the primitive circle and an oblique circle, is equal to the tangent of half the inclination of those circles; and the distance of their centres is equal to the tangent of their inclination, the semidiameter of the primitive being radius. For let AC (fig. 9.) be the diameter of a circle, whose poles are P and Q, and inclined to the plane of projection in the angle AIF; and let *a*, *c*, *p*, be the projections of the points A, C, P; also let HaE be the projected oblique circle, whose centre is *g*. Now when the plane of projection becomes the primitive circle, whose pole is I, then is *Ip* = tangent of half the angle AIF, or of half the arch AF; and *Iq* = tangent of AF, or of the angle FHa = AIF.

6. If through any given point in the primitive circle, an oblique circle is described, then the centres of all other oblique circles passing through that point, will be in a right line drawn through the centre of the first oblique circle, and perpendicular to a line passing through that centre, the given point, and the centre of the primitive circle. Thus, let GACE (fig. 10.) be the primitive circle, and ADEI a great circle described through D, its centre being B. HK is a right line drawn through B, perpendicular to a right line CI passing through D and B and the centre of the primitive circle. Then the centres of all other

great circles, as FDH, passing through D, will fall in the line HK.

7. Equal arcs of any two great circles of the sphere will be intercepted between two other circles drawn on the sphere through the remotest poles of those great circles. For let PBEA (fig. 11) be a sphere, on which AGB and CFD are two great circles, whose remotest poles are E and P; and through these poles let the great circle PBEC and the small circle PGE be drawn, cutting the great circles AGB and CFD in the points B, G, D, F. Then are the intercepted arcs BG and DF equal to one another.

8. If lines are drawn from the projected pole of any great circle, cutting the peripheries of the projected circle and plane of projection, the intercepted arcs of those peripheries are equal; that is, the arc BG = *df*.

9. The radius of any lesser circle, whose plane is perpendicular to that of the primitive circle, is equal to the tangent of that lesser circle's distance from its pole; and the secant of that distance is equal to the distance of the centres of the primitive and lesser circle. For let P (fig. 12) be the pole and AB the diameter of a lesser circle, its plane being perpendicular to that of the primitive circle, whose centre is C: then *d* being the centre of the projected lesser circle, *da* is equal to the tangent of the arc PA, and *dC* = the secant of PA.

The above is merely a general view of this subject: they who want to go farther into it, may advantageously consult Emerson's treatise on Projection, that in Robertson's Navigation, that in bishop Horsley's Elementary Treatises, and those in Lacaille's and Vince's Astronomy, and a very elegant one in Puissant's *Traite de Topographie, d'Arpentage, et de Nivellement*.

PROJECTOR. *s.* (from *project*.) 1. One who forms schemes and designs (*Addison*). 2. One who forms wild impracticable schemes (*Pope*).

PROJECTION. *s.* (*projeture*, Fr. *pro-jectura*, Lat.) A jutting out.

To PROIN. *v. a.* (a corruption of *prune*.) To lop; to cut; to trim; to prune (*Ben Jonson*).

PROLAPSUS. (from *prolabor*, to slip down.) A protrusion. A genus of disease in the class locales, and order ectopix of Cullen; distinguished by the falling down of a part that is uncovered.

To PROLATE. *v. a.* (*prolatum*, Lat.) To pronounce; to utter (*Howel*).

PROLATE. *a.* (*prolatus*, Latin.) Extended beyond an exact round (*Cheyne*).

PROLATE, in geometry, an epithet applied to a spheroid produced by the revolution of a semi-ellipsis about its larger diameter.

PROLATION. *s.* (*prolatus*, Latin.) 1. Pronunciation; utterance (*Ray*). 2. Delay; act of deferring (*Ainsworth*).

PROLATION, in music. A method used in the old music of determining the power of semibreves and minims. The mark of prola-

## PRO

tion was placed after the cliff, and sometimes after the sign of the mode, by a circle, or semicircle, punctuated, or unpunctuated, according to the following rules: the prolation was divided into perfect and imperfect, and each into major or minor, in the same manner as the mode.

The perfect prolation was for the ternary measure, and was marked by a point in a circle when major, and by a point in a semicircle when minor.

The imperfect prolation was for the binary measure, and was marked by a single circle when major, and by a semicircle when minor.

**PROLEGOMENA.** *s.* (*προλογισματα*.) Previous discourse; introductory observations.

**PROLEPSIS.** *s.* (*προληψις*.) 1. A form of rhetoric, in which objections are anticipated (*Bramhall*). 2. An error in chronology by which events are dated too early (*Theobald*).

**PROLEPTICAL.** *a.* (from *prolepsis*.) Previous; antecedent (*Glänville*).

**PROLEPTICALLY.** *ad.* (from *proleptical*.) By way of anticipation (*Clarissa*).

**PROLETARIAN.** *a.* Mean; wretched; vile; vulgar (*Hudibras*).

**PROLIFEROUS STEM.** In botany. *Explicis centro tantum emittens ramos.* Putting forth branches only from the centre of the top: as in pinus.—Proliferous flower.—*E centro floris alium protrudens.*—*Cum intra florem (sepius plenum) alii flores enascuntur.* Having smaller flowers growing out of the principal one: as in chiding daisy.—Proliferous umbel. *Plusquam decomposita.* Every compound umbel is twice divided. In a proliferous umbel, the umbellule is subdivided.

**PROLIFICATION.** *s.* (*proles* and *facio*, Latin.) Generation of children (*Brown*).

**PROLIFICAL.** **PROLIFIC.** *a.* (*prolificus*, Fr.) Fruitful; generative; pregnant; productive (*Dryden*).

**PROLIFICALLY.** *ad.* (from *prolific*.) Fruitfully; pregnantly.

**PROLIX.** *a.* (*prolixus*, Latin.) 1. Long; tedious; not concise (*Digby*). 2. Of long duration (*Ayliffe*).

**PROLIXIOUS.** *a.* (from *prolix*.) Dilatory; tedious; not used (*Shakspeare*).

**PROLIXITY.** *s.* (*prolixité*, French.) Tediousness; tiresome length; want of brevity (*Boyle*).

**PROLIXLY.** *ad.* (from *prolix*.) At great length; tediously (*Dryden*).

**PROLIXNESS.** *s.* (from *prolix*.) Tediousness.

**PROLOCUTOR.** *s.* (Lat.) The foreman; the speaker of a convocation (*Swift*).

**PROLOCUTORSHIP.** *s.* (from *prolocutor*.) The office or dignity of prolocutor.

**PROLOGUE.** *s.* (*προλογος*.) 1. Preface; introduction to any discourse or performance (*Milton*). 2. Something spoken before the entrance of the actors of a play (*Shakspeare*).

**To PROLOGUE.** *v. a.* (from the noun.) To introduce with a formal preface (*Shakspeare*).

**To PROLONG.** *v. a.* (*prolonger*, French.)

## PRO

1. To lengthen out; to continue; to draw out (*Milton*). 2. To put off to a distant time (*Shakspeare*).

**PROLONGATION.** *s.* (*prolongation*, Fr.) 1. The act of lengthening (*Bacon*). 2. Delay to a longer time (*Bacon*).

**PROLUSION.** *s.* (*prolusio*, Latin.) Entertainments; performance of diversion (*Hake-will*).

**PROME**, a city of Pegu, capital of a province of the same name. It was formerly more considerable, and the metropolis of the kingdom, but has been greatly reduced by frequent wars. Much teak timber is sent hence to Rangoon. It is seated on the Irrawaddy, 120 miles N.W. of Pegu. Lon. 95.0 W. Lat. 18. 50 N.

**PROMETHEUS**, in fabulous history, a son of Japetus, by Clymene, was brother to Atlas, and Epimetheus, and surpassed all mankind in cunning. He ridiculed the gods, and deceived Jupiter himself. To punish Prometheus and the rest of mankind, Jupiter took fire away from the earth, but the son of Japetus climbed the heavens by the assistance of Minerva, and stole fire from the chariot of the sun. This provoked Jupiter much; he ordered Vulcan to make a woman of clay, and after he had given her life, he sent her to Prometheus, with a box of the most valuable presents. (See **PANDORA**.) Prometheus, suspecting Jupiter, took no notice of Pandora, but made Epimetheus marry her, and the god, now more irritated, caused this artful mortal to be tied to a rock on mount Caucasus, where, for 30,000 years, a vulture was to feed upon his liver, which was never to be diminished. He was delivered from this punishment 30 years afterwards by Hercules. According to Apollodorus, Prometheus made the first man and woman that ever were upon the earth, with clay, which he animated by means of the fire which he had stolen from heaven. To him mankind are indebted for the invention of many of the useful arts.

**PROMETHIS**, and **PROMETHIDES**, a patronymic applied to the children of Prometheus as to Deucalion, &c.

**PROMINENCE.** **PRO'MINENCY.** *s.* (*prominentia*, Latin.) Protuberance; extant part (*Addison*).

**PROMINENT.** *a.* (*prominens*, Latin.) Standing out beyond the other parts; protuberant; extant (*Brown*).

**PROMISCUOUS.** *a.* (*promiscuus*, Latin.) Mingled; confused; undistinguished (*Tillotson*).

**PROMISCUOUSLY.** *ad.* With confused mixture; indiscriminately (*Sandys*).

**PROMISE.** *s.* (*promissum*, Latin.) 1. Declaration of some benefit to be conferred (*Dryden*). 2. Performance of promise; grant of the thing promised (*Acts*). 3. Hopes; expectation (*Shakspeare*).

**To PROMISE.** *v. a.* (*promitto*, Latin.) To make declaration of some benefit to be conferred (*Temple*).

To PRO'MISE. *v. n.* To assure one by a promise (*Dryden*).

PRO'MISEBREACH. *s.* (*breach* and *promise*.) Violation of promise: not in use (*Shakspeare*).

PRO'MISEBREAKER. *s.* (*promise* and *break*.) Violator of promises (*Shakspeare*).

PRO'MISER. *s.* (from *promise*.) One who promises (*Ben Jonson*).

PRO'MISSORILY. *ad.* (from *promissory*.) By way of promise (*Brown*).

PRO'MISSORY. *a.* (*promissorius*, Latin.) Containing profession of some benefit to be conferred (*Arbutnot*).

PRO'MONT. PRO'MONTORY. *s.* (*promontorium*, Latin.) A headland; a cape; high land jutting into the sea (*Suckling*, *Pope*).

To PROMOTE. *v. a.* (*promoveo*, *promotus*, Latin.) 1. To forward; to advance (*Milton*). 2. (*promouvoir*, Fr.) To elevate; to exalt; to prefer (*Milton*).

PROMO'TER. *s.* (*promoteur*, French.) 1. Advancer; forwarder; encourager (*Atterbury*). 2. Informer; makebate: obsolete (*Tusser*).

PROMO'TION. *s.* (*promotion*, Fr.) Advancement; encouragement; exaltation to some new honour or rank; preferment (*Milton*).

To PROMO'VE. *v. a.* (*promoveo*, Latin.) To forward; to advance; to promote (*Suckling*).

PROMPT. *a.* (*prompt*, Fr. *promptus*, Lat.) 1. Quick; ready; acute; easy (*Clarendon*). 2. Quick; petulant (*Dryden*). 3. Ready without hesitation; wanting no new motive (*Dryden*). 4. Ready; told down: as, *prompt* payment.

To PROMPT. *v. a.* (*prontare*, Italian.) 1. To assist by private instruction; to help at a loss (*Stillingfleet*). 2. To dictate (*Pope*). 3. To incite: to instigate (*Shakspeare*). 4. To remind (*Brown*).

PROMPTER. *s.* (from *prompt*.) 1. One who helps a public speaker, by suggesting the word to him when he falters (*Shakspeare*). 2. An admonisher; a reminder (*L'Estrange*).

PROMPTITUDE. *s.* (*promptitude*, Fr.) Readiness; quickness.

PROMPTLY. *ad.* (from *prompt*.) Readily; quickly; expeditiously (*Taylor*).

PROMPTNESS. *s.* (from *prompt*.) Readiness; quickness; alacrity (*South*).

PROMPTUARY. *s.* (*promptuarium*, Lat.) A storehouse; a repository; a magazine (*Woodward*).

PROMPTURE. *s.* (from *prompt*.) Suggestion; instigation: not used (*Shakspeare*).

To PROMU'LGATE. *v. a.* (*promulgo*, Latin.) To publish; to make known by open declaration (*Locke*).

PROMULGATION. *s.* (*promulgatio*, Latin.) Publication; open exhibition (*South*).

PROMULGATOR. *s.* (from *promulgate*.) Publisher; open teacher (*Decay of Piety*).

To PROMU'LGE. *v. a.* (from *promulgo*, Latin.) To promulgate; to publish; to teach openly (*Atterbury*).

PROMU'LGER. *s.* (from *promulge*.) Publisher; promulgator (*Atterbury*).

PRONATION. The act of turning the palm of the hand downwards. It is performed by rotating the radius upon the ulna, by means of several muscles which are termed pronators; as,

PRONATOR RADII QUADRATUS, in anatomy. This, which has gotten its name from its use and its shape, is a small fleshy muscle, situated at the lower and inner part of the fore arm, and covered by the tendons of the flexor muscles of the hand. It arises tendinous and fleshy from the lower and inner part of the ulna, and runs nearly in a transverse direction, to be inserted into that part of the radius which is opposite to its origin, its inner fibres adhering to the interosseous ligaments. This muscle assists in the pronation of the hand, by turning the radius inwards.

PRONATOR RADII TERES, in anatomy. This is a small muscle, situated at the upper and anterior part of the fore-arm. It is called *teres*, to distinguish it from the pronator quadratus. It arises tendinous and fleshy from the anterior and inferior part of the outer condyle of the os humeri; and tendinous from the coronoid process of the ulna, near the insertion of the brachialis internus. The median nerve passes between these two portions. From these origins the muscle runs obliquely downwards and outwards, and is inserted, tendinous and fleshy, into the anterior and convex edge of the radius, about the middle of that bone. This muscle, as its name indicates, serves to turn the hand inwards.

PRONE. *a.* (*pronus*, Latin.) 1. Bending downward; not erect (*Milton*). 2. Lying with the face downward; contrary to *supine* (*Brown*). 3. Precipitous; headlong; going downward (*Milton*). 4. Declivous; sloping (*Blackmore*). 5. Inclined; propense; disposed (*South*).

PRONENESS. *s.* (from *prone*.) 1. The state of bending downward; not erectness (*Brown*). 2. The state of lying with the face downward; not supineness. 3. Descent; declivity. 4. Inclination; propension; disposition to ill (*Hooker*).

PRONG. *s.* (*pronghen*, Dutch, to squeeze.) A fork (*Sandys*).

PRONITY. *s.* (from *prone*.) Proneness (*More*).

PRONOU'N. *s.* (*pronomen*, Lat.) A word that is used instead of the proper name. It is a declinable part of speech. See GRAMMAR.

To PRONOUN'CE. *v. a.* (*prononcer*, Fr. *pronuncio*, Latin.) 1. To speak; to utter (*Jeremiah*). 2. To utter solemnly; to utter confidently (*Shakspeare*). 3. To form or articulate by the organs of speech (*Holder*).

To PRONOU'NCE. *v. n.* To speak with confidence or authority (*South*).

PRONOUN'NCER. *s.* (from *pronounce*.) One who pronounces (*Ayliffe*).

PRONUNCIATION, in grammar, the manner of articulating or sounding the words of a language.

Among living languages the pronunciation of the French is the most difficult: and especially in that most of their words have two different pronunciations, the one in common prose, the other in verse.

As to the pronunciation of the English language, Mr. Martin, in his Spelling-book of Arts and Sciences, lays down the following rules: 1. The final (e) lengthens the sound of the foregoing vowel; as in *can, cane; rob, robe; tun, tune, &c.* 2. The final (e), in words ending in *re*, is sounded before the *r* like *u*; as, *massacre, massa-cur; lucre, lucur, &c.* 3. The Latin diphthongs, *æ, œ*, are sounded like *e*; as *Ætna, Etna; æconomy, economy, &c.* but at the end of the words *œ* sounds like *o*; as in *toe, foe, &c.* 4. Also the English improper diphthongs, *ea, eo, eu, ue*, only sound the *e* and *u*; as *tea or te; feeffee, or fessée; due or du; true or tru, &c.* though sometimes *eo* and *ea* are pronounced like *ee*, as in *people, fear, near, &c.* 5. Sometimes the diphthong (*ie*) is pronounced like *e* in *cieling*, like *ee* in *field*, and at the end of words always like *y*, as in *lie, &c.* and *ei* is pronounced either like *e* or *ai*, as in *deceit, reign, &c.* 6. The triphthong *eau* is pronounced like *o*, in *beau and jet d'eau*; and *ieu* sounds like *u* in *lieu, adieu, &c.* 7. The sound of *c* is hard before the vowels *a, o, u*, as in *call, cold, cup, &c.* also sometimes before *h*, as in *chart, chord, &c.* and before *l* and *r*, as in *clear, creep, &c.* It is otherwise generally soft, as in *city, cell, cyder, child, &c.* 8. In French words *ch* is sounded like *sh*, as in *chagreen, machine*; and sometimes like *qu*, as in *choir.* 9. The sound of *g* is hard before *a, o, u, l, r*, as in *gall, go, gum, glean, grope*; also before *ui*, as in *guilt, guild, &c.* and before *h*, as *ghost*; sometimes before *i*, as in *gibbous, gibberish.* It is also generally hard before *e*, as in *get, geld, &c.* but soft in many words derived from the Greek and Latin, as in *geometry, genealogy, genus, &c.* Two *gg* are always hard, as in *dagger, &c.* The sound of *g*, when soft, is like that of *j.* 10. In any part of a word, *ph* sounds like *f*, as in *philosophy, &c.* 11. The sound of *qu*, at the end of French words, is like *k*, as in *risque, &c.* 12. The syllables *ti* and *ci*, if followed by a vowel, sound like *si* or *shi*; as in *fiction, logician, &c.* 13. When *cc* occurs before *i*, the first is hard and the latter soft: as in *flaccid, &c.* 14. The letter *p* is not pronounced at the beginning of syllables before *s* and *t*; as in *psalm, ptarmics, &c.* As to other peculiarities regarding the pronunciation of single letters, many of them have been taken notice of at the beginning of each, in the course of this work.

But it is not enough to know the just pronunciation of single letters, but also of words: in order to which the accenting of words ought to be well understood; since nothing is more harsh and disagreeable to the ear, than to hear a person speak or read with wrong accents. And indeed in English the same word is often both a noun and a verb, distinguished only by the accent, which is on the first syllable of the noun, and on the last of the verb; as, *ferment*

and *ferment*; *ricord* and *record*, &c. We are to observe also, that in order to a just expression of words, some require only a single accent on the syllable, as in *tórmént, &c.*; but in others it should be marked double, as in *a'nímal*, because it is pronounced as if the letter were written double, viz. *animal*.

The pronunciation of words in a living language must, doubtless, be subject to slight and almost imperceptible modifications from custom and habit: but it behoves all men of literature to resist, as far as may be, the invasion of *fashion* into the province of language. Otherwise oral language, being exposed to the changes suggested by the caprice, or fancy, or vanity of those who suppose themselves capable of introducing new modes, without possessing one qualification that fits them for the undertaking, will, instead of presenting an orderly harmonious whole, be reduced to a ridiculous chaotic mass.

We believe that popular actors on the stage have been tempted to take greater liberties in this respect than any other class of men; and on this point we believe Mr. Kemble has a just load of censure lying at his door. The vagaries rendered current by this gentleman and his imitators are such, as if the great formers of the standard of the English language, Addison, Swift, Pope, Lowth, &c. were now living, would cause them to be sneered at by half the boarding-school young ladies in the kingdom, for their boorish, uncouth manner of pronouncing words. We will venture to produce, miscellaneous, a few specimens of the liberties taken with the language by the sort of persons to whom we now refer; and leave it to the good sense of our young readers to avoid the whole class of improprieties which this short list will suggest to them.

|            |            |                     |
|------------|------------|---------------------|
| Perfume,   | pronounced | <i>perf-yume.</i>   |
| Premature, |            | <i>prema-chure.</i> |
| Gratitude, |            | <i>grati-chude.</i> |
| Solitude,  |            | <i>solí-chude.</i>  |
| Tuesday,   |            | <i>Tchuse-day.</i>  |
| Tulip,     |            | <i>tchu-lip.</i>    |
| Hughes,    |            | <i>Yews.</i>        |

Half, glass, &c. with the *a* sounded like a *im hat* instead of like *a* in *call*.—Acceptable, with the accent on the first syllable, instead of the second.

PROOF. *s.* (from *prove*.) 1. Evidence; testimony; convincing token; means of conviction (*Locke*). 2. Test; trial; experiment (*Milton*). 3. Firm temper; impenetrability (*Dryden*). 4. Armour hardened till it will abide a certain trial (*Shakspeare*). 5. In printing, the rough draught of a sheet when first pulled.

PROOF, the shewing or making plain the truth of any matter alleged; either in giving evidence to a jury on a trial, or else on interrogatories or by copies of records, or exemplifications of them. See EVIDENCE.

PROOF of artillery and small arms, is a trial whether they stand the quantity of powder allotted for that purpose. The rule of the board of ordnance is, that all guns under 24-

pounders are loaded with powder as much as their shot weighs; that is, a brass 24-pounder with 21 lb. a brass 32-pounder with 26 lb. 12 oz. and a 42-pounder with 31 lb. 8 oz. the iron 24-pounder with 18 lb. the 32-pounder with 21 lb. 8 oz. and the 42-pounder with 25 lb.

The brass light field-pieces are proved with powder that weighs half as much as their shot, except the 24-pounder, which is loaded with 10 lb. only.

Government allows 11 bullets of lead in the pound for the proof of muskets; and 14.5, or twenty-nine in two for service; seventeen in the pound for the proof of carbines, and twenty for service; twenty-eight in the pound for the proof of pistols, and thirty-four for service.

When guns of a new metal, or of lighter construction, are proved; then, besides the common proof, they are fired 200 or 300 times, as quick as they can be loaded with the common charge given in actual service. Our light six-pounders were fired 300 times in three hours and twenty-seven minutes, loaded with 1 lb. 4 oz. without receiving any damage.

**PROOF of powder**, is in order to try its goodness and strength. See **GUNPOWDER**.

**PROOF of cannon**, is made to ascertain their being well cast, their having no cavities in the metal, and in a word, their being fit to resist the effort of their charge of powder. When guns are rejected by the proof-masters, they order them to be marked  $\times$  thus, which the contractors generally alter *WP* thus; and after such alteration dispose of them to foreign powers for Woolwich proof.

The most curious instrument for finding the principal defects in pieces of artillery was invented by lieutenant-general Desaguliers, of the royal artillery. This ingenious instrument, which is nearly upon the principle of some of our pyrometers, is no sooner introduced into any part of the interior of a gun than it magnifies and points out its defects, and more particularly that of the piece not being truly bored; which is a very important one, and to which most of the disasters happening to pieces of artillery are in a great measure to be imputed; for, when a gun is not truly bored, the most expert artillerist will not be able to make a good shot.

**PROOF of mortars and howitzers**, is made to ascertain their being well cast, and of strength to resist the effort of their charge. For this purpose the mortar or howitzer is placed upon the ground, with some part of their trunnions or breech sunk below the surface, and resting on wooden billets, at an elevation of about 70 degrees. The mirror is generally the only instrument to discover the defects in mortars and howitzers. In order to use it the sun must shine; the breech must be placed towards the sun, and the glass over against the mouth of the piece: it illuminates the bore and chamber sufficiently to discover the flaws in it.

**PROOF of foreign brass artillery**.—1. The Prussians. Their battering-train and garrison

artillery are proved with a quantity of powder equal to half the weight of the shot, and fired 75 rounds as fast as in real service; that is, 2 or 3 rounds in a minute. Their light field-train, from a twelve-pounder upwards, are proved with a quantity of powder = 1-3d of the weight of the shot, and fired 150 rounds, at three or four rounds in a minute. From a twelve-pounder downwards, are proved with a quantity of powder = 1-5th of the shot's weight and fired 300 rounds, at five or six rounds each minute, properly spunged and loaded. Their mortars are proved with the chambers full of powder, and the shells loaded. Three rounds are fired as quick as possible. 2. The Dutch prove all their artillery by firing each piece five times: the two first rounds with a quantity of powder = 2-3ds of the weight of the shot; and the three last rounds with a quantity of powder = half the weight of the shot. 3. The French the same as the Dutch.

**PROOF**, in brandy and other spirituous liquors, is a little white lather which appears on the top of the liquor when poured into a glass. This lather, as it diminishes, forms itself into a circle called by the French the *chapelet*, and by the English the bead or bubble.

**PROOFS of prints**, were anciently a few impressions taken off in the course of an engraver's process. He proved a plate in different states, that he might ascertain how far his labours had been successful, and when they were complete. The excellence of such early impressions, worked with care, and under the artist's eye, occasioning them to be greedily sought after, and liberally paid for, it has been customary among our modern printers to take off a number of them, amounting, perhaps to hundreds, from every plate of considerable value; and yet their want of rareness has by no means abated their price. On retouching a plate, it has been also usual, among the same conscientious fraternity, to cover the inscription, which was immediately added after the first proofs were obtained, with slips of paper, that a number of secondary proofs might also be created.

**PROOF. a.** Impenetrable; able to resist (*Collier*).

**PROOFLESS. a.** (from *proof*.) Unproved; wanting evidence (*Boyle*).

**To PROP. v. a.** (*proppe*, Dutch.) 1. To support by placing something under or against (*Milton*). 2. To support by standing under or against (*Creech*). 3. To sustain; to support (*Pope*).

**PROP. s.** (*proppe*, Dutch.) A support; a stay; that on which any thing rests. See **FULCRUM**.

**PROPAGABLE. a.** (from *propagate*.) Such as may be spread (*Boyle*).

**To PROPAGATE. v. a.** (*propago*, Lat.) 1. To continue or spread by generation or successive production (*Otway*). 2. To extend; to widen (*Shakspeare*). 3. To carry on from place to place; to promote (*Newton*). 4. To increase; to promote (*Shakspeare*). 5. To generate (*Clarissa*).

To PRO'PAGATE. *v. n.* To have offspring (*Milton*).

PROPAGATION. *s.* (*propagatio*, Latin.) Continuance or diffusion by generation or successive production (*Wiseman*).

PROPAGATOR. *s.* (from *propagate*.) 1. One who continues by successive production. 2. A spreader; a promoter (*Addison*).

PROPAGO. *Sēmen musci decorticationem, detectum 1750.* A peculiar name given by Linnæus to the seeds of mosses; because he supposed them to differ from other seeds in having a naked corcle or heart, without cotyledons: a discovery which he made in 1750.

To PROPEL. *v. a.* (*propello*, Latin.) To drive forward (*Harvey*).

To PROPEND. *v. n.* (*propendo*, Lat. to hang forward.) To incline to any part; to be disposed in favour of any thing (*Shakspeare*).

PROPENSITY. *s.* (from *propend*.) 1. Inclination or tendency of desire to any thing. 2. (from *propendo*, Latin, to weigh.) Preconsideration; attentive deliberation; perpendency (*Hale*).

PROPENSE. *a.* (*propensus*, Lat.) Inclined; disposed (*Milton*).

PROPENSION. PROPENSITY. *s.* (*propensio*, Fr. *propensio*, Lat.) 1. Moral inclination; disposition to any thing good or bad (*Rogers*). 2. Natural tendency (*Digby*).

PROPER. *a.* (*proprius*, Latin.) 1. Peculiar; not belonging to more; not common (*Davies*). 2. Noting an individual (*Watts*). 3. One's own (*Shakspeare*). 4. Natural; original (*Milton*). 5. Fit; accommodated; adapted; suitable; qualified (*Dryden*). 6. Exact; accurate; just. 7. Not figurative (*Burnet*). 8. It seems in *Shakspeare* to signify, mere; pure. 9. (*propre*, Fr.) Elegant; pretty (*Heb.*). 10. Tall; lusty; handsome with bulk (*Shakspeare*).

PROPER RECEPTACLE, in botany. *Quod partes unius tantum fructificationis respicit.* That which respects the parts of a single fructification: in opposition to a common receptacle, connecting several florets, as in the aggregate flowers.—Proper perianth.—Involucre. A proper perianth, or involucre, respecting one flower only. As in simple flowers. Aggregate flowers have usually both a calyx common to the whole, and a perianth proper to each floret. Proper flower or corol. One of the single florets or corollets in aggregate flowers: in opposition to the common or compound flower, consisting of the aggregate of florets, making one whole. Proper nectary. Separate from the petals and other parts of the flower.

PROPERLY. *ad.* (from *proper*.) 1. Fitly; suitably. 2. In a strict sense (*Milton*).

PROPERNESS. *s.* (from *proper*.) 1. The quality of being proper; 2. Talness.

PROPERTIUS (*Sextus Aurelius*), a Latin poet, born in Umbria. His father was a Roman knight, proscribed by Augustus. He came to Rome, where his genius soon recommended him to the notice of the great. *Mecænas*, *Gallus*, and *Virgil* became his friends,

and Augustus his patron. *Mecænas* wished him to attempt an epic poem, of which he proposed the emperor for hero, but *Propertius* refused to undertake the task. He died about 19 years before Christ, in the 40th year of his age. His works consist of four books of elegies, written with so much vivacity and energy, that many authors call him the prince of the elegiac poets among the Latins. *Cynthia*, the heroine of his elegies, was a Roman lady, whose real name was *Hostia* or *Hostilia*. *Propertius* has usually a place assigned him in the editions of *Tibullus* and *Catullus*: but the best edition of *Propertius* is that which was given separately by *Janus Brouckhusius* at Amsterdam, 1702, in 4to, and again in 1714, 4to, *cum curis secundis ejusdem*. There is a respectable edition in 4to, by *Lantanius*, date 1780.

PROPERTY. *s.* (from *proper*.) 1. Peculiar quality (*Hooker*). 2. Quality; disposition (*South*). 3. Right of possession (*Locke*). 4. Possession held in one's own right (*Dryden*). 5. The thing possessed (*Swift*). 6. Nearness or right (*Shakspeare*). 7. Something useful; an appendage (*Dryden*).

To PRO'PERTY. *v. a.* Not now used. 1. To invest with qualities (*Shakspeare*). 2. To seize or retain as something owned; to appropriate; to hold (*Shakspeare*).

PROPHASIS. *s.* (*προφησῖς*.) In medicine, a foreknowledge of diseases.

PROPHECY, is a word derived from *προφητεία*, and in its original import signifies the prediction of future events.

As God alone can perceive with certainty the future actions of free agents, and the remote consequences of those laws of nature which he himself established, prophecy, when clearly fulfilled, affords the most convincing evidence of an intimate and supernatural communion between God and the person who uttered the prediction. Together with the power of working miracles, it is indeed the only evidence which can be given of such a communion. Hence, among the professors of every religious system, except that which is called the religion of nature, there have been numberless pretenders to the gift of prophecy. The Pagan nations of antiquity had their oracles, augurs, and soothsayers. Modern idolators have their necromancers and diviners; and the Jews, Christians and Mahometans have their seers and prophets.

The ill-founded pretensions of paganism, ancient and modern, have been exposed under various articles of this work. (See *DIVINATION*, *MAGIC*, *NECROMANCY*, and *MYTHOLOGY*.) And the claims of the Arabian impostor are examined under the articles *ALCORAN* and *MAHOMETANISM*; so that at present we have only to consider the use, intent, and truth of the Jewish and Christian prophecies.

Previous to our entering on this investigation, it may be proper to observe, that, in the scriptures of the Old and New Testaments, the signification of the word prophecy is not always confined to the foretelling of future events. In

## PROPHECY.

several instances it is of the same import with preaching, and denotes the faculty of illustrating, and applying to present practical purposes, the doctrines of prior revelation. Thus, in Nehemiah it is said, "Thou hast appointed prophets to preach;" and whoever speaketh unto men to edification, and exhortation, and comfort, is by St. Paul called a prophet. Hence it was that there were schools of prophets in Israel, where young men were instructed in the truths of religion, and fitted to exhort and comfort the people.

In this article, however, it is chiefly of importance to confine ourselves to that kind of prophecy which, in declaring truths either past, present, or future, required the immediate inspiration of God.

Every one who looks into the history of the world must observe, that the minds of men have from the beginning been gradually opened by a train of events still improving upon, and adding light to each other; as that of each individual is, by proceeding from the first elements and seeds of science, to more enlarged views and a still higher growth. Mankind neither are nor ever have been capable of entering into the depths of knowledge at once; of receiving a whole system of natural or moral truths together; but must be let into them by degrees, and have them communicated by little and little, as they are able to bear it. That this is the case with respect to human science is a fact which cannot be questioned; and there is a little room to question it with respect to the progress of religious knowledge among men, either taken collectively or in each individual. Why the case is thus in both, why all are not adult at once in body and mind, is a question which the religion of nature is equally called upon with revelation to answer. The fact may not be easily accounted for, but the reality of it is incontrovertible.

Accordingly, the great object of the several revelations recorded in the Old Testament was evidently to keep alive a sense of religion in the minds of men, and to train them by degrees for the reception of those simple but sublime truths by which they were to be saved. The notions which the early descendants of Adam entertained of the Supreme Being, and of the relation in which they stood to him, were probably very gross; and we see them gradually refined by a series of revelations or prophecies, each in succession more explicit than that by which it was preceded, till the advent of Him who was the way, the truth, and the life, and who brought to light life and immortality.

In order to form a right judgment of the argument for the truth of Christianity drawn from the sure word of prophecy, we must not consider the prophecies given in the Old Testament as so many predictions only independent of each other; for, if we do, we shall totally lose sight of the purpose for which they were originally given, and shall never be able to satisfy ourselves when confronted by the objections of unbelievers. It is easy for men of leisure and tolerable parts to find difficulties in

VOL. IX.

particular predictions, and in the application of them made by writers who lived many hundred years ago, and who had many ancient books and records of the Jewish church, from which they drew many passages, and perhaps some prophecies; which books and records we have not, to enable us to understand and to justify their applications. But it is not so easy a matter to show, or to persuade the world to believe, that a chain of prophecies reaching through several thousand years, delivered at different times, yet manifestly subservient to one and the same administration of providence from beginning to end, is the effect of art and contrivance and religious fraud. In examining the several prophecies recorded in the Old Testament, we are not to suppose that each of them expressly pointed out and clearly characterised Jesus Christ. Had they done so, instead of being a support to religion in general, the purpose for which they were originally intended, they would have had a very different effect, by making those to whom they were given repine at being placed under dispensations so very inferior to that of the gospel. We are therefore to inquire only whether all the notices, which, in general and often metaphorical terms, God gave to the fathers, of his intended salvation, are perfectly answered by the coming of Christ; and we shall find, that nothing has been promised with respect to that subject which has not been performed in the amplest manner. If we examine the prophecies in this manner, we shall find that there is not one of them, which the Apostles have applied to the Messiah, that is not applicable in a rational and important sense to something in the birth, life, preaching, death, resurrection, and ascension of Jesus of Nazareth; that, as applied to him, they are all consistent with each other; and that, though some few of them may be applied without absurdity to persons and events under the Jewish dispensation, Christ is the only person that ever existed in whom they all meet as in a centre. In the limits prescribed us, it is impossible that we should enter upon a particular proof of this position. It has been proved by numberless writers, and, with respect to the most important prophecies, by none with greater success than bishop Sherlock in his *Use and Intent of Prophecy in the several Ages of the World*; a work which we recommend to our readers, as one of the most valuable on the subject in our own or any other language.

But, admitting that it would have been improper, for the reasons already hinted at, to have given a clear and precise description of Christ, and the Christian dispensation, to men who were ordained to live under dispensations less perfect—how, it may be asked, comes it to pass, that many of the prophecies applied by the writers of the gospel to our Saviour and his actions are still dark and obscure, and so far from belonging evidently to him and to him only, that it requires much learning and sagacity to show even now the connection between some prophecies and the events?

Y Y

## P R O P H E C Y .

In answer to these questions, the learned prelate just referred to observes, "That the obscurity of prophecy does not arise from hence, that it is a relation or description of something future; for it is as easy to speak of things future plainly, and intelligibly, as it is of things past or present. It is not, therefore, of the nature of prophecy to be obscure; for it may easily be made, when he who gives it thinks fit, as plain as history." On the other side, a figurative and dark description of a future event will be figurative and dark still when the event happens; and consequently will have all the obscurity of a figurative and dark description as well after as before the event. The prophet Isaiah describes the peace of Christ's kingdom in the following manner: "The wolf shall dwell with the lamb, and the leopard shall lie down with the kid, and the calf and the young lion, and the faling; together, and a little child shall lead them." Nobody, some modern Jews excepted, ever understood this literally; nor can it now be literally applied to the state of the gospel. It was and is capable of different interpretations: it may mean temporal peace, or that internal and spiritual peace—that tranquillity of mind, which sets a man at peace with God, himself, and the world. But, whatever the true meaning is, this prophecy does no more obtrude one determinate sense upon the mind since the coming of Christ than it did before. But then we say, the state of the gospel was very properly prefigured in this description, and is as properly prefigured in a hundred more of the like kind; and since they all agree in a fair application to the state of the gospel, we strongly conclude, that this state was the thing foretold under such expressions. So that the argument from prophecy for the truth of Christianity does not rest on this, that the event has necessarily limited and ascertained the particular sense and meaning of every prophecy; but in this, that every prophecy has in a proper sense been completed by the coming of Christ. It is absurd, therefore, to expect clear and evident conviction from every single prophecy applied to Christ: the evidence must arise from a view and comparison of all together." It is doubtless a great mistake to suppose that prophecy was intended solely or chiefly for their sakes in whose time the events predicted are to happen. What great occasion is there to lay in so long beforehand the evidence of prophecy to convince men of things that are to happen in their own times; the truth of which they may, if they please, learn from their own senses? Yet some people are apt to talk, as if they thought the truth of the events predicted depended very much on the evidence of prophecy: they speak, for instance, as if they imagined the certainty and reality of our Saviour's resurrection were much concerned in the clearness of the prophecies relating to that great and wonderful event, and seem to think that they are confuting the truth of his resurrection when they are pointing out the absurdity of the prophecies relating to it. But can any thing be more absurd? For, what

ground or pretence is there to inquire, whether the prophecies foretelling that the Messiah should die, and rise again, do truly belong to Christ, unless we are first satisfied that Christ died, and rose again?

The part which unbelievers ought to take in this question, if they would make any use of prophecy, should be, to show from the prophets that Christ was necessarily to rise from the dead; and then to prove that in fact Jesus never did rise. Here would be a plain consequence. But, if they like not this method, they ought to let the prophecies alone; for, if Christ did not rise, there is no harm done though the prophets have not foretold it. And if they allow the resurrection of Christ, what do they gain by discrediting the prophets? The event will be what it is, let the prophecies be what they will.

These considerations show how far the gospel is necessarily concerned in prophetic evidence, and how clear the prophecies should be. Christ claims to be the person foretold in the law and the prophets; and, as truth must ever be consistent with itself, this claim must be true as well as all others. This is the part then to be tried on the evidence of prophecy: Is Christ that person described and foretold under the Old Testament, or not? Whether all the prophecies relating to him be plain or not plain, it matters little; the single question is, Are there enough plain, to show us that Christ is the person foretold under the Old Testament? If there be, we are at an end of our inquiry, and want no further help from prophecy; especially since we have seen the day dawn, and enjoyed the marvellous light of the gospel of God.

But so unreasonable are unbelievers, that, whilst some of them object to the obscurity of the prophecies, others have rejected them altogether on account of their clearness, pretending that they are histories, and not predictions. The prophecies against which this objection has been chiefly urged are those of Daniel, which were first called in question by the famous Porphyry. He affirmed that they were not composed by Daniel, whose name they bear, but by some author who lived in Judea about the time of Antiochus Epiphanes; because all to that time contained true history, but that all the facts beyond that were manifestly false.

This method of opposing the prophecies, as a father of the church rightly observes, is the strongest testimony of their truth; for they are so exactly fulfilled, that to infidels the prophet seemed not to have foretold things future, but to have related things past. To an infidel of this age, if he has the same ability and knowledge of history that Porphyry had, all the subsequent prophecies of Daniel, except those which are still fulfilling, would appear to be history, and not prophecy: for it entirely overthrows the notion of their being written in the days of Antiochus Epiphanes, or of the Maccabees, and establishes the credit of Daniel as a prophet beyond contradiction, that there

are several of those prophecies which have been fulfilled since that period as well as before; nay, that there are prophecies of Daniel which are fulfilling at this very time in the world.

We might here subjoin many prophecies both from the Old and the New Testament, and especially from the writings of St. Paul and St. John, which so clearly describe the various fortunes of the Christian church, her progress to that state of general corruption under which she was sunk three centuries ago, and her gradual restoration to her primitive purity, that they cannot be supposed to proceed from the cunning craftiness of men, or to have been written after the events of which they speak. To do justice to these, however, would require a volume, and many excellent volumes have been written upon them. The reader who wishes for satisfaction on so interesting a subject will do well to consult the writings of Mr. Mede and sir Isaac Newton, together with bishop Newton's Dissertations, and the Sermons of Hurd, Halifax, and Bagot, preached at Warburton's lecture. We shall only observe, that one of the ablest reasoners that Great Britain ever produced, (Dr. Clarke) after having paid the closest attention to the predictions of the New Testament, has been bold enough to put the truth of revealed religion itself upon the reality of that prophetic spirit which foretold the desolation of Christ's church and kingdom by antichrist. "If," says he, "in the days of St. Paul and St. John, there was any footstep of such a sort of power as this in the world; or if there had been any such power in the world; or if there was then any appearance or probability that could make it enter into the heart of man to imagine that there ever could be any such kind of power in the world, much less in the temple or church of God; and if there be not now such a power actually and conspicuously exercised in the world; and if any picture of this power, drawn after the event, can now describe it more plainly and exactly than it was originally described in the words of the prophecy—then may it with some degree of plausibility be suggested, that the prophecies are nothing more than enthusiastic imaginations."

Upon the whole, we conclude with bishop Sherlock, that the various prophecies recorded in the Holy Scriptures were given, not to enable man to foresee with clearness future events, but to support the several dispensations of religion under which they were respectively promulgated. The principal prophecies recorded in the Old Testament led mankind to hope for a complete deliverance from the curse of the fall; and therefore tended to fill their minds with gratitude, and to enforce a cheerful obedience to that God who in the midst of judgement remembereth mercy. The prophecies, whether in the Old or New Testament, that portray the present state of the Jews, and the various fortunes of the Christian church, as they are daily fulfilling in the presence of all men, are the strongest possible proof of the divinity

of our holy religion, and supply to us in the latter days the place of miracles, by which it was at first established.

In addition to the preceding references, we beg to point to Lowth on Isaiah, Horsley on Hosea, Abbadie on the Prophecies, Smith's Summary View of the Writings of the Prophets (a very comprehensive and useful work in small compass), Dr. Collyer's Lectures on Prophecy, and the Essay on the same subject in Dr. Gregory's Letters on the Evidences, Doctrines, and Duties of the Christian Religion.

PROPHESIER. *s.* (from *prophecy*.) One who prophesies.

To PROPHESY. *v. a.* 1. To predict, to foretell (*Shakspeare*). 2. To foreshow (*Sh.*).

To PROPHESY. *v. n.* 1. To utter predictions (*Shakspeare*). 2. To preach. A scriptural sense (*Ezekiel*).

PROPHET. *s.* (*prophete*, Fr. *προφητης*.) 1. One who tells future events; a predictor; a foreteller (*Dryden*). 2. One of the sacred writers empowered by God to display futurity (*Shakspeare*).

PROPHET. (*propheta*, *προφητης*.) A person inspired by God with the knowledge of future events; and commissioned to declare his laws, his will, &c. to the world.

The word is derived from the Greek *προ*, and *φημι*, said; of *φημι*, I say; whence also the Latins derive their *fatus*, spoken.

Among the canonical books are those of sixteen prophets; four of which are denominated the greater prophets, viz. Isaiah, Jeremiah, Ezekiel, and Daniel; so called from the length or extent of their writings, which exceed those of the others: viz. Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habbakuk, Haggai, Zechariah, and Malachi; who are called the lesser prophets, from the shortness of their writings.

The writings of the prophets form one of the three divisions of the canon of the Old Testament; and to those already enumerated, called the books of the latter prophets, are added those of the former prophets; viz. Joshua, Judges, Samuel, and Kings.

The Jews only reckon three greater prophets: Daniel they exclude, as no more to be ranked among the prophets than David; not but that both the one and the other foretold many important things, but because their manner of life differed from that of the other prophets; David being a king, and Daniel a peer.

In the Greek church, the lesser prophets are placed in order before the great ones; apparently, because many of the lesser prophets are more ancient than the greater.

Among the Greeks, too, Daniel is ranked among the lesser prophets. In the forty-eighth chapter of Ecclesiasticus, Isaiah is particularly called the great prophet; both on account of the great things he foretold, and the magnificent manner wherein he did it.

Spinoza says, the several prophets prophesied according to their respective humours: Jeremiah, e. gr. melancholy, and dejected

with the miseries of life, prophesied nothing but misfortunes.

Dacier observes, that, among the ancients, the name poet is sometimes given to prophets; as that of prophet is, at other times, given to poets.

**PROPHETESS.** *s.* (*prophetesse*, French.) A woman that foretells future events (*Peach.*).

**PROPHETICAL.** **PROPHETIC.** *a.* (*prophetique*, Fr.) Foreseeing or foretelling future events (*Stillingfleet*).

**PROPHETICALLY.** *ad.* (from *prophetical*.) With knowledge of futurity; in manner of a prophecy (*Hammond*).

**To PROPHETIZE.** *v. n.* (*prophetiser*, Fr.) To give predictions: not in use (*Daniel*).

**PROPHYLACTIC.** *a.* (*προφυλακτικός*.) Preventive; preservative (*Watts*).

**PROPHYLACTICS.** (*προφυλακτικα*, from *προ*, before, and *φυλασσω*, to defend.) Any means made use of to preserve health.

**PROPINQUITY.** *s.* (*propinquitas*, Latin.)

1. Nearness; proximity; neighbourhood (*Ray*).  
2. Nearness of time (*Brown*). 3. Kindred; nearness of blood (*Shakspeare*).

**PROPTIABLE.** *a.* (from *propitiate*.) Such as may be induced to favour; such as may be made propitious.

**To PROPTIATE.** *v. a.* (*propitio*, Latin.) To induce to favour; to gain; to conciliate; to make propitious (*Stillingfleet*).

**PROPTIATION.** *s.* (*propitiation*, Fr.)

1. The act of making propitious. 2. The atonement; the offering by which propitiousness is obtained (*Johnson*).

**PROPTIATOR.** *s.* (from *propitiate*.) One that propitiates.

**PROPTIATORY.** *a.* (*propitiatoire*, Fr.) Having the power to make propitious (*Still*).

**PROPTIOUS.** *a.* (*propitius*, Lat. *propice*, Fr.) Favourable; kind (*Addison*).

**PROPTIOUSLY.** *ad.* (from *propitius*.) Favourably; kindly (*Roscommon*).

**PROPTIOUSNESS.** *s.* (from *propitius*.) Favourableness; kindness (*Temple*).

**PROPLASM.** *s.* (*πρόπλασμα* and *πλασμα*.) Mould; matrix (*Woodward*).

**PROPLASTICE.** *s.* (*προπλαστική*.) The art of making moulds for casting.

**PROPONENT.** *s.* (from *proponens*, Lat.) One that makes a proposal, or lays down a position (*Dryden*).

**PROPONTIS**, a sea which has a communication with the Euxine, by the Thracian Bosphorus, and with the Ægean by the Hellespont, now called the sea of Marmora.

**PROPORTION.** *s.* (*proportion*, French; *proportio*, Latin.) 1. Comparative relation of one thing to another; ratio (*Raleigh*). 2. Settled relation of comparative quantity; equal degree (*Addison*). 3. Harmonic degree (*Milton*). 4. Symmetry; adaptation of one to another (*Addison*). 5. Form; size (*Davies*).

**To PROPORTION.** *v. a.* (*proportionner*, Fr.) 1. To adjust by comparative relation (*Addison*). 2. To form symmetrically (*Sidney*).

**PROPORTION**, in mathematics, the equality or similitude of ratios. As the four numbers

4, 8, 15, 30 are proportionals, or in proportion, because the ratio of 4 to 8 is equal or similar to the ratio of 15 to 30, both of them being the same as the ratio of 1 to 2.

Euclid, in the 5th definition of the 5th book, gives a general definition of four proportionals, or when, of four terms, the first has the same ratio to the 2d, as the 3d has to the 4th, viz. when any equimultiples whatever of the first and third being taken, and any equimultiples whatever of the 2d and 4th; if the multiple of the first be less than that of the 2d, the multiple of the 3d is also less than that of the 4th; or if the multiple of the first be equal to that of the 2d, the multiple of the 3d is also equal to that of the 4th; or if the multiple of the first be greater than that of the 2d, the multiple of the 3d is also greater than that of the 4th. And this definition is general for all kinds of magnitudes or quantities whatever, though it is a very obscure one.

Also, in the 7th book, Euclid gives another definition of proportionals, viz. when the first is the same equimultiple of the 2d, as the 3d is of the 4th, or the same part or parts of it. But this definition appertains only to numbers and commensurable quantities.

Proportion is often confounded with ratio; but they are quite different things. For, ratio is properly the relation of two magnitudes or quantities of one and the same kind; as the ratio of 4 to 8, or of 15 to 30, or of 1 to 2; and so implies or respects only two terms or things. But proportion respects four terms or things, or two ratios which have each two terms. Though the middle term may be common to both ratios, and then the proportion is expressed by three terms only, as 4, 8, 64, where 4 is to 8 as 8 to 64.

Proportion is also sometimes confounded with progression. In fact, the two often coincide; the difference between them only consisting in this, that progression is a particular species of proportion, being indeed a continued proportion, or such as has all the terms in the same ratio, viz. the 1st to the 2d, the 2d to the 3d, the 3d to the 4th, &c.; as the terms 2, 4, 8, 16, &c.; so that progression is a series or continuation of proportions.

Once more, as Dr. Clarke very justly remarked in his controversy with Leibnitz, proportions are not quantities but the proportions of quantities, and the same may be said of ratios. If they were quantities, they would be the quantities of quantities; which is absurd. Besides, if they were quantities, they would, like all other quantities, increase always by addition. But the addition of the ratio of 1 to 1, to that of 1 to 1, makes still no more than that of 1 to 1; and the addition of the ratio of a half to one, to that of 1 to 1, does not make the proportion of 1 and a half to 1, but that only of a half to 1. That which mathematicians sometimes inaccurately call the quantity of proportion, is (accurately and strictly speaking) only the quantity of the relative or comparative magnitude of one thing with regard to another; and

# P R O P O R T I O N .

proportion is not the comparative magnitude itself, but the comparison or relation of the magnitude to another. The relation of 6 to 1, with regard to that of 3 to 1, is not a double quantity of proportion, but the proportion of a double quantity. And, in general, what they call bearing a greater or less proportion, is not bearing a greater or less quantity of proportion or relation, but bearing the proportion or relation of a greater or less quantity, to another: it is not a greater or less quantity of comparison, but the comparison of a greater or less quantity. The reader will see, that all this is perfectly consistent with our definition of mathematics.

Proportion is either continual, or discrete or interrupted.

The proportion is continual when every two adjacent terms have the same ratio, or when the consequent of each ratio is the antecedent of the next following ratio, and so all the terms form a progression; as 2, 4, 8, 16, &c.; where 2 is to 4 as 4 to 8, and as 8 to 16, &c.

Discrete or interrupted proportion, is when the consequent of the first ratio is different from the antecedent of the 2d, &c.; as 2, 4, and 3, 6.

Proportion is also either direct or inverse.

*Direct proportion* is when more requires more, or less requires less. As it will require more men to perform more work, or fewer men for less work, in the same time.

*Inverse or reciprocal proportion*, is when more requires less, or less requires more. As it will require more men to perform the same work in less time, or fewer men in more time. Ex. If 6 men can perform a piece of work in 15 days, how many men can do the same in 10 days. Then,  
 Reciprocally - as  $\frac{1}{15}$  to  $\frac{1}{10}$  so is 6 : 9 the an-  
 or inversely - as 10 to 15 so is 6 : 9 swer.

Proportion again, is distinguished into arithmetical, geometrical, and harmonical.

*Arithmetical proportion* is the equality of two arithmetical ratios, or differences. As in the numbers 12, 9, 6; where the difference between 12 and 9, is the same as the difference between 9 and 6, viz. 3.

And here the sum of the extreme terms is equal to the sum of the means, or to double the single mean when there is but one. As  $12 + 6 = 9 + 9 = 18$ .

*Geometrical proportion* is the equality between two geometrical ratios, or between the quotients of the terms. As in the three 9, 6, 4, where 9 is to 6 as 6 is to 4, thus denoted  $9 : 6 :: 6 : 4$ ; for  $\frac{9}{6} = \frac{6}{4}$ , being each equal  $\frac{3}{2}$  or  $1\frac{1}{2}$ .

And in this proportion, the rectangle or product of the extreme terms, is equal to that of the two means, or the square of the single mean when there is but one. For  $9 \times 4 = 6 \times 6 = 36$ .

*Harmonical proportion*, is when the first term is to the third, as the difference between the 1st and 2d is to the difference between the 2d and 3d; or in four terms when the 1st is to the 4th, as the difference between the 1st and 2d is to the difference between the 3d and 4th;

or the reciprocals of an arithmetical proportion are in harmonical proportion. As 6, 4, 3; because  $6 : 3 :: 6 - 4 = 2 : 4 - 3 = 1$ ; or because  $\frac{1}{6}, \frac{1}{4}, \frac{1}{3}$  are in arithmetical proportion, making  $\frac{1}{6} + \frac{1}{3} = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}$ . Also the four 24, 16, 12, 9 are in harmonical proportion, because  $24 : 9 :: 8 : 3$ . See PROPORTIONALS.

PROPORTION (Compass of), a name by which the French, and some English authors, call the sector.

PROPORTION (Rule of), in arithmetic, a rule by which a 4th term is found in proportion to three given terms. And is popularly called the golden rule, or rule of three.

PROPORTIONS (Animal). The relative magnitudes, shapes and adaptations of the different parts of an animal, upon which his beauty and perfection depend, and by which his powers are materially affected. Many authors have conceived it impossible to lay down any general rules of just proportion for animals; and others have doubted their practical utility, even if it could be done with precision.

There has, more especially, been much dispute upon this subject in regard to a perfect horse; the proportions of which, we are confident, must correspond, although it is unquestionably true that, in the noted horse Eclipse, we have a case which seems to set all calculation at defiance; yet this is to be considered, though a strong, yet as only an extraordinary exception, and proves merely that the application of any general rule should not be indiscriminate. Mr. Feron, in his late System of Farriery, notwithstanding Mr. St. Bel's account of the defective structure of Eclipse, in several particulars, ventures to give the following as the exact and invariable proportions of the best race horses.

He prefaces his account by observing, that the head of a horse, divided into twenty-two parts, has been the usual scale for measuring every other part of the body; but, if the animal's head should appear either too long or too short, as sometimes is the case, he says, that measure must be abandoned, and instead of it we are to take the height of the body from the top of the withers to the ground. On the third part of this measure he relies for ascertaining the just length of every other part of the body; and also for shewing how much the head happens to be defective.

We have endeavoured to exhibit Mr. Feron's demonstrations from his own plates, No. 27, and following, where *w, w, w*, shew what the author denominates a well-made horse, and beautiful in his forehead. He measures three heads and sixteen parts, from the top of the head to the ground, provided the head stands in its natural position, which, however, it is not always easy to ascertain.

*g, g*, Shews the neck, which should measure one head and thirteen parts, from the withers to the top of the head. The same measure is given for the length of the neck, from the top of the head to its junction with the chest.

*a, a, a*, Shews the height of the body, which should measure three heads, from the withers

# PROPORTION.

to the ground. The same measure holds good from the rump to the ground, which Mr. Feron says exposes the false idea of making horses appear higher before than behind, when they are to be viewed.

*b, b, b, b,* Shews the length of the body, which should measure three heads and four parts, from the point of the shoulder to the posterior part of the buttock of the animal.

*d, d,* Mr. Feron describes as the line which falls from the articulation of the shoulder with the arm. This, which should measure two heads, and seven parts, ought directly to touch the hoof, in front of the toe. "If," says he, "the foot should stand before this line, the leg will be in an oblique direction forward, which structure will confine the horse in all its actions, because the fore-legs are obliged to come upon the ground nearly the same way as those of a horse on the descent (or going down hill), that is to say, the heels will touch the ground first, instead of the toes; but if the legs stand obliquely backwards from above, which is the opposite defect before-mentioned, the case is a deal worse, because the animal is continually stumbling, and even falling, on account of the feet being drawn too much under the belly, which situation obliges him to support too great a weight of the body. When this defect originates from the knees only, it bends the legs more or less, in which case the horse is called bow-legged. In either case, such an animal must be rejected, and considered as unfit for the turf."

In *e, e,* we have the line which falls from the top of the fore-leg to the point of the heel. This line, which should measure one head and twenty parts, is intended to show the importance of a perfect perpendicular position of the fore-leg.

*f, f,* Is the distance from the top of the withers to the stifle, which ought to measure one head and twenty parts. By the same measure the distance from the rump to the elbow may be determined.

*h,* In width, the neck should measure one head from the top of the withers to the point of the shoulder.

*i, i,* Shows the narrowest part of the neck, and the breadth of the head taken a little below the eyes. The measure given for these is twelve parts of a head each.

In thickness, the body, from the middle of the back to that of the belly, is stated at one head and two parts. *c, c, c,* A continuation of the same line to the ground, shows the animal's centre of gravity.

*k, k,* The distance from the root of the tail to the stifle, should measure one head and four parts. A repetition of these letters shows first, the length from the stifle to the hock; secondly, the distance from the hock to the ground.

By *m,* the breadth of the fore-arm may be ascertained. This, if taken from the anterior parts to the elbow, should measure eleven parts of a head. *m,* In the hinder parts, gives the breadth of one of the legs, taken just under the fold of the buttock.

*n,* Shows the breadth of the hock, taken from its anterior part to the top of the os calcis. This measures seven parts of a head. The same measure (sideway) gives the breadth of the head, above the nostrils.

The forehead, in breadth, taken from one eye to the other, should measure seven parts of a head. The same gives the distance between the fore-legs.

In a well-proportioned horse, the knees, in thickness, should measure five parts of a head; and the same measure gives the breadth of the fore-legs, just above the knees, as at *l*.

*p,* Is the breadth of the hind fetlock joints, which should be four parts of a head.

*t,* The fore-pasterns, which should measure two parts of a head and three-quarters.

*v, v,* The breadth of the coronet. This should measure four and a half parts of a head.

*o,* The breadth of the hinder legs or shank-bones, viz. three parts of a head.

*r,* In breadth, the fore-legs should measure two parts of a head and three-quarters.

*a, a, a,* Is a perpendicular line, which falls from the articulation of the stifle. "This," says Mr. Feron, "should touch the ground at the distance of half a head from the toe. Too far or too near this direction proves the hock defective. If the hind feet advance too much under the belly, the hocks must be proportionably bent, and the weight of the body overcharging them, will of course increase the deformity. The feet being too much under the belly will render it impossible for them to cover much ground; therefore their steps will be very much confined. The extension of the hocks terminating almost in an upright direction, will rather serve to raise the body than to push it forward.

"If, on the contrary, the hind feet stand too far behind this line, the hocks will be too strait, and their flexion too confined. The extension of the hinder parts taking place only in a perpendicular direction backward, will produce a defect capable of retarding the speed."

The author is aware of the general opinion, of those who are deemed good judges of horses, that the hind feet ought never to pass over the fore feet, but this he thinks erroneous. "Nevertheless," says he, "it is an obvious fact, that the extension of the hind quarters, and the freedom in the action of the hind legs, in a well-bred horse, convey the hind-feet very much beyond the fore-feet; and this I know to be the case with every animal which nature has designed for speed. A bad organization in the structure of the hock gives also a bad direction to the feet, by turning them inwards or outwards; in either case it is precisely ascertained that the legs lose more or less of their power, because they do not perform their actions upon the line of the body; therefore such mechanism must be considered as a fault in hunters or racers, &c."

Mr. Feron observes here, that a bad organization in the thigh bone, as in case of its inclin-

ing outwards, gives a bad direction to all the rest of the limb, by bringing the point of the hocks together, and tending to turning the feet outwards

"But," says he, "whether the hock bends outwards or inwards, the fault is considerable in either case, for the reason already observed, that the legs cannot move upon the line of the body. The croup will waver to the right and left; of course, a horse of this kind will labour a great deal more than one whose proportion is good: besides, all these lateral motions are absolutely contrary to the actions of a good horse; for which reason I recommend to every one to be very particular in a true and exact proportion in the hind legs, inasmuch as the slightest defect in this part must effectually retard the speed. It is not so bad with regard to the fore-leg, whose function is rather to support the body than push it forwards."

Mr. Feron contends that the foregoing proportions must unavoidably exist in a thoroughbred horse, and that they indeed constitute the most beautiful and important quality of his structure: and any one who gives to the subject the necessary degree of attention, will soon discover those proportions in a horse which indicate superior activity and speed. To render this more easy, the author, after supposing the different organs defective in their proportions, endeavours to point out the consequences resulting from defects in the head, neck, back, loins, chest, &c. These minutiae, however, can only be effectually understood by consulting the work itself, and the plates to which we have referred, which are 27 and following.

Mr. St. Bel, in his elaborate Essay on the Proportions of Eclipse, preceded Mr. Feron in the plan of calculating the powers of progression. The points in which that celebrated racer differed from the standard of general excellence may be ascertained by a comparison of the foregoing with Mr. St. Bel's account, where will be found a second plate, which represents the motions of the legs.

It appears, that the height and length of Eclipse were, from the withers to the ground, 66 inches. His height from the top of the rump to the ground 67 inches. The length of his body, taken from the most prominent part of the breast to the extremity of the buttocks, 69 inches.

The length of the bones which composed his limbs, is stated thus:

| <i>Fore legs.</i>                  | Inches. |
|------------------------------------|---------|
| The shoulder blade                 | 18      |
| The humerus or arm                 | 12      |
| The cubitus or fore-arm            | 16      |
| The canon or shank                 | 12      |
| The pastern, the coronet, and foot | 7       |

| <i>Hind legs.</i>                  | Inches. |
|------------------------------------|---------|
| The os-ilium                       | 12      |
| The femur                          | 15      |
| The tibia                          | 19      |
| The shank or leg                   | 14      |
| The pastern, the coronet, and foot | 9       |

Mr. St. Bel describes the extent of flexion in the several parts which composed the extremities in Eclipse thus:

## 1. In the fore extremities.

"The shoulder describes the portion of a circle equal to 40 degrees, both forward and backward; the centre of its motion being in the middle of the shoulder blade.

"The humerus, or arm, represented in the centre of flexion backward, describes 40 degrees in its action.

"The cubitus, or fore-arm, taken at the beginning of its flexion forward, describes 90 degrees in its action.

"The shank, or canon, at the commencement of its flexion backward, describes 90 degrees in its action.

"The pastern, coronet, and foot, describe one with another, in their flexion backward, 100 degrees."

## 2. In the hinder extremities.

"The haunch, or os ilium, bending upward and downward, describes 30 degrees in its action.

"The femur, or thigh bone, taken in the middle of its flexion forward, describes 50 degrees.

"The tibia, at one third of its flexion backward, describes, in the whole, 80 degrees.

"The shank, in the beginning of its flexion forward, describes 100 degrees.

"The pastern, coronet, and foot, describe, one with another, 100 degrees in their action."

From this statement, Mr. St. Bel shows, "that the legs of Eclipse, in their flexion in the gallop, described each a circle of 360 degrees; and, consequently, the extent of the action of each leg was the same in the extension.

"To this," says he, "must be added the force of action, without which a horse cannot even walk. This force depends chiefly on the power of the muscles, and can only be computed by experiment; since they are animated organs, which move parts merely mechanical: but, in allowing Eclipse a good muscular organization, which he certainly possessed, we may, examining the length and direction of his legs, and the greatness and openness of the angles, formed by the alternate disposition of the bones which composed his extremities, pronounce with the greatest probability, that Eclipse, free of all weight, and galloping at liberty in his greatest speed, could cover an extent of 25 feet at each complete action on the gallop; that he could repeat this action twice and one-third in each second; consequently, that, employing without reserve all his natural and mechanical faculties on a straight line, he could run nearly four miles in the space of six minutes and two seconds."

The author shows, by a diagram, six complete actions of the gallop. In these the four prints of the feet of Eclipse, which are marked

before and behind, show where he placed his hind and fore feet in the gallop.

The professor's succeeding remarks on the defects observable in the construction of the several parts of this extraordinary animal are too much in detail to admit even of abridgment, within a moderate compass. The reader of them, however, though he may have his doubts as to the accuracy of this mode of calculating the powers of a living animal, will not fail, at least, to admire the ingenuity of the attempt.

**PROPORTIONABLE.** *a.* (from *proportion*.) Adjusted by comparative relation; such as is fit (*Tillotson*).

**PROPORTIONABLY.** *ad.* (from *proportion*.) According to proportion; according to comparative relations (*Rogers*).

**PROPORTIONAL.** *a.* (*proportionel*, Fr.) Having a settled comparative relation; having a certain degree of any quality compared with something else (*Newton*).

**PROPORTIONAL COMPASSES.** See **COMPASSES**.

**PROPORTIONAL PART,** is a part of some number that is analogous to some other part or number; such as the proportional parts in the logarithms, and other tables.

**PROPORTIONAL SCALES,** called also **Logarithmic scales,** are the logarithms, or artificial numbers, placed on lines, for the ease and advantage of multiplying and dividing, &c. by means of compasses, or of sliding rulers. These are in effect so many lines of numbers, as they are called by Gunter, but made single, double, triple, or quadruple; beyond which they seldom go. See **GUNTER'S SCALE, SCALE,** &c.

**PROPORTIONAL SPIRAL.** See **SPIRAL**.

**PROPORTIONALITY.** *s.* (from *proportional*.) The quality of being proportional (*Grew*).

**PROPORTIONALLY.** *ad.* (from *proportional*.) In a stated degree (*Newton*).

**PROPORTIONALS,** are the terms of a proportion; consisting of two extremes, which are the first and last terms of the set, and the means, which are the rest of the terms. These proportionals may be either arithmeticals, geometricals, or harmonicals, and in any number above two, and also either continued or discontinued.

Pappus gives this beautiful and simple comparison of the three kinds of proportionals, arithmetical, geometrical, and harmonical, viz. *a, b, c*, being the first, second and third terms in any such proportion, then

$$\left. \begin{array}{l} \text{In the arithmeticals, } a : a \\ \text{In the geometricals, } a : b \\ \text{In the harmonicals, } a : c \end{array} \right\} :: a - b : b - c.$$

See **MEAN PROPORTIONAL**.

Continued proportionals form what is called a **progression**; for the properties of which see **ARITHMETICAL, GEOMETRICAL, and HARMONICAL**.

When four quantities are in proportion, they are also in proportion by inversion, compo-

sition, division, &c.; thus, *a, na, b, nb*, being in proportion, viz.,

1.  $a : na :: b : nb$ ; then by
2. Inversion  $na : a :: nb : b$ ;
3. Alternation  $a : b :: na : nb$ ;
4. Composition  $a + na : na :: b + nb : nb$ ;
5. Conversion  $a + na : a :: b + nb : b$ ;
6. Division  $a - na : a :: b - nb : b$ ;

**PROPORTIONATE.** *a.* (from *proportion*.) Adjusted to something else, according to a certain rate or comparative relation (*Grew*).

**TO PROPORTIONATE.** *v. a.* (from *proportion*.) To adjust according to settled rates to something else (*Bentley*).

**PROPORTIONATENESS.** *s.* (from *proportionate*.) The state of being by comparison adjusted (*Hale*).

**PROPOSAL.** *s.* (from *propose*.) 1. Scheme or design propounded to consideration or acceptance (*Addison*). 2. Offer to the mind (*South*).

**TO PROPOSE.** *v. a.* (*proposer*, Fr.) To offer to the consideration (*Watts*).

**TO PROPOSE.** *v. n.* To lay schemes (*Shakespeare*).

**PROPOSER.** *s.* (from *propose*.) One that offers any thing to consideration (*Swift*).

**PROPOSITION.** *s.* (*proposition*, French; *propositio*, Latin.) 1. One of the three parts of a regular argument (*White*). 2. A sentence in which any thing is affirmed or decreed (*Hammond*). 3. Proposal; offer of terms (*Clarendon*).

**PROPOSITION,** in logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject, as, "God is just." While the comparing of our ideas is considered merely as the act of the mind, assembling them together, and joining or disjoining them according to the result of its perceptions, this operation is called judgment. But when these judgments are expressed in words, they then bear the name of propositions. Hence a proposition is a sentence expressing some judgment of the mind, whereby two or more ideas are affirmed to agree or disagree: and as our judgments include at least two ideas, one of which is affirmed or denied of the other; so a proposition must have terms corresponding to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the subject of the proposition; and the idea affirmed or denied, as also the term answering to it, is called its predicate; thus in the proposition, God is omnipotent, God is the subject, it being of him that we affirm omnipotence; and omnipotent is the predicate, because we affirm the idea expressed by that word to belong to God.

**PROPOSITION,** in mathematics, is either some truth advanced and shown to be such by demonstration, or some operation proposed and its solution shown. If the proposition be deduced from several theoretical definitions compared together, it is called a theorem; if from

a praxis, or series of operations, it is called a problem.

**PROPOSITION**, in poetry, the first part of a poem wherein the author proposes briefly, and in general, what he is to say in the body of his work. It should comprehend only the matter of the poem, that is, the action and the persons that act. Horace prescribes modesty and simplicity in the proposition, and would not have the poet promise too much, nor raise in the reader too great ideas of what he is going to relate.

**PROPOSITIONAL**. *a.* (from *proposition*.) Considered as a proposition (*Watts*).

**To PROPOUND**. *v. a.* (*propono*, Latin.) 1. To offer to consideration; to propose (*Wotton*). 2. To offer; to exhibit (*Shakspeare*).

**PROPOUNDER**. *s.* (from *propound*.) He that propounds; he that offers; proposer.

**PROPRIETARY**. *s.* (*proprietaire*, Fr. from *propriety*.) Possessor in his own right (*Government of the Tongue*).

**PROPRIETARY**. *a.* Belonging to a certain owner (*Grew*).

**PROPRIETOR**. *s.* (from *proprius*, Latin.) A possessor in his own right (*Rogers*).

**PROPRIETRESS**. *s.* (from *proprietor*.) A female possessor in her own right (*L'Es-trange*).

**PROPRIETY**. *s.* (*proprietas*, Latin.) 1. Peculiarity of possession; exclusive right (*Suckling*). 2. Accuracy; justness (*Locke*).

**PROPT**. for *propped*. (from *prop*.) Sustained by some prop (*Pope*).

**PROPTOMA**. (*proptoma*, *προπτωμα*, from *προπτωω*, to fall down.) A relaxation of the scrotum, of the under lip, of the breasts in females, of the præpæ, or of the ears.

**To PROPUGN**. *v. a.* (*propugno*, Latin.) To defend; to vindicate (*Hammond*).

**PROPUGNATION**. *s.* (*propugnatio*, from *propugno*, Latin.) Defence (*Shakspeare*).

**PROPUGNER**. *s.* (from *propugn*.) A defender (*Government of the Tongue*).

**PROPULSION**. *s.* (*propulsus*, Latin.) The act of driving forward (*Bacon*).

**PRO NATA**, a mercantile term for in proportion; thus, it is said each person in a joint concern must reap the profit, or sustain the loss, *pro nata* to his interest.

**PRORE**. *s.* (*prora*, Lat.) The prow; the forepart of a ship (*Pope*).

**PROROGATION**. *s.* (*prorogatio*, Latin.)

1. Continuance; state of lengthening out to a distant time; prolongation (*South*). 2. Interruption of the session of parliament by the regal authority (*Swift*).

**To PROROGUE**. *v. a.* (*prorogo*, Latin.) 1. To protract; to prolong (*Dryden*). 2. To put off; to delay (*Shakspeare*). 3. To withhold the session of parliament to a distant time.

**PRORUPTION**. *s.* (*proruptus*, Lat.) The act of bursting out (*Brown*).

**PROSAIC**. *a.* (*prosaïque*, Fr.) Belonging to prose; resembling prose.

**To PROSCRIBE**. *v. a.* (*proscribo*, Latin.)

1. To censure capitally; to doom to destruction (*Roscommon*). 2. To interdict: not in use (*Dryden*).

**PROSCRIBER**. *s.* (from *proscribe*.) One that dooms to destruction (*Dryden*).

**PROSCRIPTION**. *s.* (*proscriptio*, Latin.) Doom to death or confiscation (*B. Jonson*).

**PROSE**. *s.* (*prose*, Fr. *prosa*, Lat.) Language not restrained to harmonic sounds or set number of syllables (*Swift*).

**To PROSECUTE**. *v. a.* (*prosecutus*, Lat.)

1. To pursue; to continue endeavours after any thing (*Milton*). 2. To continue; to carry on (*Hayward*). 3. To proceed in consideration or disquisition of any thing (*Holder*). 4. To pursue by law; to sue criminally.

**PROSECUTION**. *s.* (from *prosecute*.) 1. Pursuit; endeavour to carry on (*South*). 2. Suit against a man in a criminal cause.

**PROSECUTOR**. *s.* (from *prosecute*.) One that carries on any thing; a pursuer of any purpose; one who pursues another by law in a criminal cause.

**PROSELYTE**. *s.* (*προσηλυτῆς*; *proselite*, Fr.) A convert; one brought over to a new opinion (*Cleaveland*).

**To PROSELYTE**. *v. a.* To convert. A bad word (*Government of the Tongue*).

**PROSEMINATION**. *s.* (*proseminatus*, Latin.) Propagation by seed (*Hale*).

**PROSERPINA**, **PROSERPINE**, in fabulous history, a daughter of Ceres by Jupiter, called by the Greeks Persephone. She was so beautiful, that Jupiter himself became enamoured of her. She made Sicily the place of her residence, and delighted in the flowery meadows and limpid streams which beautified the plains of Enna. From this solitary retreat, Pluto carried her away into the infernal regions, of which she became the queen. (See **PLUTO**.) Ceres, disconsolate at the loss of her daughter, travelled all over the world, and, at length, learned from the nymph Arethusa, that her daughter had been carried away by Pluto, whereupon she repaired to Jupiter, and demanded of him to punish the ravisher. Jupiter having in vain attempted to persuade Ceres that Pluto was not unworthy of her daughter, then informed her that Proserpine might return on earth, if she had not taken any aliments in the infernal regions. Unfortunately she had eaten a pomegranate, and Ascalaphus was the only one who saw it. (See **ASCALAPHUS**.) And for his discovery the goddess instantly turned him into an owl. Jupiter, however, to soothe the grief of Ceres, permitted that Proserpine should remain six months with Pluto, and the rest of the year on earth. As queen of hell, and wife of Pluto, Proserpine presided over the death of mankind, and no one could die, if herself, or Atropos (see **PARCÆ**) did not cut off one of the hairs from the head. Proserpine was universally worshipped by the ancients, and was known by the different names of Libitina, Hecate, Juno inferna.

**PROSERPINACA**, in botany, a genus of

the class triandria, order trigynia. Calyx three-parted, superior ; corollous ; nut three-celled. One species ; a marsh-plant of Virginia, with creeping root, and axillary, solitary flowers.

**PROSEUCHE**, in antiquity, properly signifies prayer ; but it is taken for the places of prayer of the Jews, and was pretty near the same as their synagogues. But the synagogues were originally in the cities, and were covered places : whereas, for the most part, the proseuches were out of the cities, and on the banks of rivers ; having no covering, except perhaps the shade of some trees or covered galleries. The word is Greek, *προευχη*, prayer.

**PROSLAMBANOMENE**, the name of a musical note in the Greek system. As the two tetrachords of the Greeks were conjunctive, or, in other words, as the highest note of the first served likewise for the lowest note of the second, it is plain that a complete octave could not be formed. To remedy this deficiency, therefore, one note beneath the lowest tetrachord was added, as an octave to the highest of the last tetrachord. Thus, if we suppose the first to have begun on B, the last must have ended on A, to which one note subjoined immediately beneath the lowest B in the diatonic order must have formed an octave. This note was called *proslambanomene*. But it appears from authors who have scrutinized antiquity with some diligence, and perhaps with as much success as the data upon which they proceeded could produce, that the names of the notes in the Greek system, which originally signified their natural station in the scale of ascending or descending sounds, were afterwards applied to their positions in the lyre. Higher or lower, then, according to this application, did not signify their degrees of acuteness or gravity, but their higher or lower situation upon this instrument.

**PROSO'DIAN**. *s.* (from *prosody*.) One skilled in metre or prosody (*Brown*).

**PROSODY**. *s.* (*προσωδία*.) The part of grammar which teaches the sound and quantity of syllables and the measures of verse.

**PROSOPIS**, in botany, a genus of the class decandria, order monogynia. Calyx hæmispheerical, four-toothed ; stigma simple ; legume many-seeded. One species ; an East Indian tree, with deeply scratched bark ; and long filiform, pendulous pods.

**PROSOPOPŒIA**, a figure in rhetoric, whereby we raise qualities, or things inanimate, into persons. This figure is divided into two parts : 1. when good and bad qualities, accidents, and things inanimate, are introduced as living and rational beings ; as in the following verses of Milton :

————— Now gentle gales,  
Fanning their odoriferous wings, dispense  
Native perfumes ; and whisper whence they  
stole

Those balmy spoils. ———

The second part of this figure is when we give a voice to inanimate things, and make

rocks, woods, rivers, buildings, &c. express the passions of rational creatures, as in the following lines of Spenser.

She foul blasphemous speeches forth did  
cast,

And bitter curses, horrible to tell,  
That ev'n the temple wherein she was  
placed

Did quake to hear, and nigh asunder burst !

**PROSPECT**. *s.* (*prospectus*, Latin.) 1. View of something distant (*Locke*). 2. Place which affords an extended view (*Milton*). 3. Series of objects open to the eye (*Addison*). 4. Object of view (*Prior*). 5. View delineated ; a picturesque delineation of a landscape (*Reynolds*). 6. View into futurity (*Smith*). 7. Regard to something future (*Tillotson*).

To **PROSPECT** *v. a.* (*prospectus*, Lat.) To look forward.

**PROSPECTIVE**. *a.* (from *prospect*.) 1. Viewing at a distance. 2. Acting with foresight (*Child*).

To **PROSPER**. *v. a.* (*prospero*, Lat.) To make happy ; to favour (*Dryden*).

To **PROSPER**. *v. n.* (*prosperer*, French.) 1. To be prosperous ; to be successful (*Isaiah*). 2. To thrive ; to come forward (*Cowley*).

**PROSPERITY**. *s.* (*prosperitas*, Latin ; *prosperité*, French.) Success ; attainment of wishes ; good fortune (*Hooker*).

**PROSPEROUS**. *a.* (*prosperus*, Lat.) Successful ; fortunate (*Milton*).

**PROSPEROUSLY**. *ad.* (from *prosperous*.) Successfully ; fortunately (*Bacon*).

**PROSPEROUSNESS**. *s.* (from *prosperous*.) Prosperity.

**PROSPICIENCE**. *s.* (from *prospicio*, Latin.) The act of looking forward

**PROSTATE GLAND**. (from *πρω*, before, and *στατω*, to stand ; because it is situated before the urinary bladder.) In anatomy, a very large, heart-like, firm gland, situated between the neck and the urinary bladder and bulbous part of the urethra. It secretes the lacteal fluid, which is emitted into the urethra by ten or twelve ducts that open near the verumontanum during coition.

**PROSTATE INFERIOR**. In anatomy. See **TRANSVERSUS PERINEI ALTER**.

**PROSTHAPHERESIS**. In astronomy. See **EQUATION OF THE CENTRE**.

To **PROSTITUTE**. *v. a.* (*prostituto*, Lat. *prostituer*, Fr.) 1. To sell to wickedness ; to expose to crimes for a reward (*Addison*). 2. To expose upon vile terms (*Tillotson*).

**PROSTITUTE**. *a.* (*prostitutus*, Latin.) Vicious for hire ; sold to infamy or wickedness ; sold to whoredom (*Prior*).

**PROSTITUTE**. *s.* (from the verb.) 1. A hireling ; a mercenary ; one who is set to sale (*Dryden*). 2. A public strumpet (*Dryden*).

**PROSTITUTION**. *s.* (*prostitution*, Fr.) 1. The act of setting to sale ; the state of being set to sale. 2. The life of a public strumpet. (*Addison*)

**PROSTRATE.** *a.* (*prostratus*, Latin.) 1. Lying at length (*Fairfax*). 2. Lying at mercy (*Shakspeare*). 3. Thrown down in humblest adoration (*Hooker*).

**To PROSTRATE.** *v. a.* (*prostratus*, Latin.) 1. To lay flat; to throw down (*Hayward*). 2. To throw down in adoration (*Duppa*).

**PROSTRATION.** *s.* (from *prostrate*.) 1. The act of falling down in adoration (*South*). 2. Dejection; depression (*Arbutnot*).

**PROSTYLE.** *s.* (*προστυλή*.) A building that has only pillars in the front.

**PROSYLLOGISM.** *s.* (*pro* and *sylogism*.) A *prosylogism* is when two or more syllogisms are so connected together, that the conclusion of the former is the major or the minor of the following (*Watts*).

**PROTAGORAS,** a Greek philosopher of Abdera, was at first a potter.—He became the disciple of Democritus, on whose system he grafted atheism, and wrote a book in defence of it which was publicly burnt at Athens, and the author banished. He died in Sicily about 400 B. C.

**PROTASIS.** *s.* (*πρωτασις*.) 1. A maxim or proposition. 2. In the ancient drama, the first part of a comedy or tragedy that explains the argument of the piece.

**PROTATIC.** *a.* (*protatique*, Fr. *πρωτατικός*.) Previous (*Dryden*).

**PROTEA.** Silver tree. In botany, a genus of the class tetandria, order monogynia. Corol four-cleft, or four-petalled; anthers linear, inserted beneath the tip of the petals; without proper calyx; nut one-seeded, superior. Sixty-five species; almost all Cape plants. They may be thus subdivided into sections

- A. Leaves pinnate, filiform.
- B. Leaves toothed, callous.
- C. Leaves filiform, subulate.
- D. Leaves linear.
- E. Leaves elliptic and lanceolate.
- F. Leaves oblong, ovate.
- G. Leaves roundish.

The two following are cultivated.

1. *P. conferta*. Cone-bearing protea. Stem erect, three feet high, with whorled subdivided branches; leaves terminated by a concave smooth gland; cone tomentose, ovate, size of a pea; floral leaves concolour.

2. *P. argentea*. Silvery protea. Strong upright stalk, covered with a purplish bark dividing into several branches which grow erect; leaves broad, shining, silvery, making a fine appearance when intermixed with other exotics; flowers in August.

Both these are sometimes raised from cuttings; but more generally by seeds obtained from the Cape.

**To PROTECT.** *v. a.* (*protectus*, Latin; *proteger*, French.) To defend; to cover from evil; to shield (*Milton*).

**PROTECTION.** *s.* (*protection*, French.) 1. Defence; shelter from evil (*Swift*). 2. A passport; exemption from being molested (*Kettlewell*).

**PROTECTIVE.** *a.* (from *protect*.) Defensive; sheltering (*Thomson*).

**PROTECTOR.** *s.* (*protecteur*, French.) 1. Defender; shelterer; supporter; one who shields from evil; guardian (*Waller*). 2. An officer who had heretofore the care of the kingdom in the king's minority (*Shakspeare*). Every Catholic nation, and every religious order, had a protector residing at the court of Rome, who was cardinal, and was called the cardinal protector. Protector is also sometimes used for a regent of a kingdom, made choice of to govern it during the minority of a prince. Cromwell assumed the title and quality of lord protector of the commonwealth of England, &c.

**PROTECTRESS.** *s.* (*protectrice*, French.) A woman that protects (*Bacon*).

**To PROTEND.** *v. a.* (*protendo*, Lat.) To hold out; to stretch forth (*Dryden*).

**PROTERVITY.** *s.* (*protervitas*, Lat.) Peevishness; petulance.

**PROTESILAUS,** a king of part of Thessaly, son of Iphiclus, married Laodamia, the daughter of Acastus, and sometime after departed for the Trojan war with 40 sail. He was the first of the Greeks who set foot on the Trojan shore, and as such he was doomed by the oracle to perish, as soon as he had leaped from his ship. Homer has not mentioned the person who killed him. His wife Laodamia destroyed herself, when she heard of his death. (See *LAODAMIA*.) He was buried on the Trojan shore.

**To PROTEST.** *v. n.* (*protestor*, Latin.) To give a solemn declaration of opinion or resolution (*Denham*).

**To PROTEST.** *v. a.* 1. To prove; to show; to give evidence of: not used (*Shakspeare*). 2. To call as a witness (*Milton*).

**PROTEST.** *s.* (from the verb.) A solemn declaration of opinion against something.

**PROTEST**, in law, is a call of witness, or an open affirmation that a person does, either not at all, or but conditionally, yield his consent to any act, or to the proceeding of any judge in a court in which his jurisdiction is doubtful, or to answer upon his oath further than he is bound by law. Any of the lords in parliament have a right to protest their dissent to any bill passed by a majority; which protest is entered in form. This is said to be a very ancient privilege. The commons have no right to protest. See *PARLIAMENT*.

**PROTEST**, in commerce, a summons written by a notary-public to a merchant, banker, or the like, to accept or discharge a bill of exchange drawn on him, after his having refused either to accept or pay it. See *BILL OF EXCHANGE*.

**PROTESTANT**, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529, they protested against a decree of the emperor Charles V. and the diet of Spire; declaring that they appealed to a general council. The same name has also been given to those of the sentiments of Calvin; and is now become a common denomination for all those who belong to the reformed churches.

**PROTESTANT.** *a.* (from *protest.*) Belonging to protestants (*Addison*).

**PROTESTATION.** *s.* (*protestation*, Fr.) A solemn declaration of resolution, fact, or opinion (*Hooker*).

**PROTESTER.** *s.* (from *protest.*) One who protests; one who utters a solemn declaration.

**PROTEUS**, a sea deity, son of Oceanus and Tethys, or according to some, of Neptune and Phœnice. He received the gift of prophecy from Neptune. He generally resided in the Carpathian sea, and reposed himself on the shore. He was difficult of access; and, when consulted, he refused to give answers, by immediately assuming different shapes, and eluding the grasp. Aristæus was in the number of those who consulted him, as also Hercules. Some suppose that he was originally a king of Egypt, known among his subjects by the name of Cetes.

**PROTHONOTARY**, a term which properly signifies first notary, and which was anciently the title of the principal notaries of the emperors of Constantinople.

Prothonotary, with us, is used for an officer in the court of king's bench and common pleas; the former of which courts has one, and the latter three. The prothonotary of the king's bench records all civil actions sued in that court, as the clerk of the crown-office does all criminal causes. The prothonotaries of the common pleas enter and enrol all declarations, pleadings, assizes, judgments, and actions: they also make out all judicial writs, except writs of *habeas corpus*, and *distringas jurator*, for which there is a particular office, called the *habeas corpora office*: they likewise enter recognizances acknowledged, and all common recoveries; make exemplifications of records, &c.

**PROTO**, a Greek term, frequently used in composition of priority: thus, proto-collum, in the ancient jurisprudence, signifies the first leaf of a book; proto-martyr, the first martyr; proto-plast, the first man formed, &c.

**PROTOGENES**, a painter of Rhodes, about 328 years B. C. originally very poor. His countrymen were ignorant of his ingenuity before Apelles came to Rhodes, and offered to buy his pieces. Protopogenes was employed for seven years in finishing a picture of Jalyus, a celebrated huntsman. He was to represent in the piece a dog panting, and with froth at his mouth, but this he never could do with satisfaction to himself; and, when all his labours seemed to be without success, he threw his sponge in anger upon the piece. Chance alone perfected what labour could not; the fall of the sponge upon the picture represented the froth at the mouth of the dog in the most natural manner, and the piece was universally admired. When Demetrius took Rhodes, the painter was found closely employed in finishing a picture; and when the conqueror asked him, why he showed not more concern at the general calamity? He replied, "Demetrius made war against the Rhodians, and not against the fine arts."

**PROTOTYPE.** *s.* (*πρωτοτυπον*.) The original of a copy; exemplar; archetype (*Stillingfleet*).

**To PROTRACT.** *v. a.* (*protractus*, Lat.) To draw out; to delay; to lengthen; to spin to length (*Knolles*).

**PROTRACT.** *s.* (from the verb.) Tedious continuance (*Spenser*).

**PROTRACTER.** *s.* (from *protract.*) 1. One who draws out any thing to a tedious length. 2. A mathematical instrument for taking and measuring angles. See **PROTRACTOR**.

**PROTRACTIION.** *s.* (from *protract.*) The act of drawing to length (*Daniel*).

**PROTRACTIVE.** *a.* (from *protract.*) Dilatory; delaying; spinning to length (*Shakspeare*).

**PROTRACTOR** is the name of an instrument used for protracting or laying down on paper the angles of a field, or other figure. The protractor is a small semicircle of brass, or other solid matter, the limb or circumference of which is nicely divided into one hundred and eighty degrees: it serves not only to draw angles on paper, or any plane, but also to examine the extent of those already laid down. For this last purpose, let the small point in the centre of the protractor be placed above the angular point, and let the side coincide with one of the sides that contain the angle proposed; then the number of degrees cut off by the other side, computing on the protractor, will show the quantity of the angle that was to be measured. See **MENSURATION**.

Protractors are now more usually made in the form of a parallelogram, and properly graduated at the upper edge.

**PROTREPTICAL.** *a.* (*προτρεπτικός*.) Hortatory; suatory (*Ward*).

**To PROTRUDE.** *v. a.* (*protrudo*, Latin.) To thrust forward (*Woodward*).

**To PROTRUDE.** *v. n.* To thrust itself forward (*Bacon*).

**PROTRUSION.** *s.* (*protrusus*, Lat.) The act of thrusting forward; thrust; push (*Locke*).

**PROTUBERANCE.** *s.* (*protubero*, Lat.) Something swelling above the rest; prominence; tumour (*Hale*).

**PROTUBERANT.** *a.* (from *protubero*.) Swelling; prominent (*Ray*).

**To PROTUBERATE.** *v. n.* (*protubero*, Lat.) To swell forward; to swell out beyond the parts adjacent (*Sharp*).

**PROUD.** *a.* (*ppude*, or *ppuz*, Saxon.) 1. Too much pleased with himself (*Watts*). 2. Elated; valuing himself (*Dryden*). 3. Arrogant; haughty; impatient (*Milton*). 4. Daring; presumptuous (*Drayton*). 5. Lofty of mien; grand of person (*Milton*). 6. Grand; lofty; splendid; magnificent (*Bacon*). 7. Ostentatious; specious; grand (*Shakspeare*). 8. Salacious; eager for the male (*Brown*). 9. Fungous; exuberant (*Arbutnot*).

**PROUDLY.** *ad.* (from *proud*.) 1. Arrogantly; ostentatiously; in a proud manner (*Dryden*). 2. With loftiness of mien (*Milton*).

**To PROVE.** *v. a.* (*probo*, Latin; *prouwer*,

## PRO

French.) 1. To evince; to show by argument or testimony (*Atterbury*). 2. To try to bring to the test (*Sandys*). 3. To experience (*Milton*). 4. To endure; to try by suffering or encountering (*Davies*).

**TO PROVE.** *v. n.* 1. To make trial (*Bacon*). 2. To be found by experience (*Shakspeare*). 3. To succeed (*Bacon*). 4. To be found in the event (*Waller*).

**PROVEABLE.** *a.* (from *prove*.) That may be proved.

**PROVEDITOR.** **PROVEDO'RE.** *s.* (*providitore*, Italian.) One who undertakes to procure supplies for an army (*Friend*).

**PROVENCE**, a late province of France, 138 miles long and 100 broad; bounded on the N. by Dauphiny, E. by the Alps and the river Var, S. by the Mediterranean, and W. by Languedoc. In that which was called Upper Provence, the soil is fertile in corn and pastures; but in Lower Provence, dry and sandy. It produces, however, wine, oil, figs, almonds, prunes, and pomegranates, along the seacoast from Toulon to Nice. There are orange and citron-trees in the open fields; and many medicinal plants, mineral waters, and mines of several kinds. Provence now forms the departments of Var, Lower Alps, and Mouths of the Rhone.

**PROVENDER.** *s.* (*provende*, Fr.) Dry food for brutes; hay and corn (*Shakspeare*).

**PROVENZALE** (Marcello), an Italian painter, born in 1575, and died in 1639. He became eminent as a painter of history and portrait, but his superior merit consisted in mosaic, which he executed with astonishing beauty.

**TO PROVERB.** *v. a.* Not a good word. 1. To mention in a proverb (*Milton*). 2. To provide with a proverb (*Shakspeare*).

**PROVERB**, (*proverbium*), is defined, by Camden, a concise, witty, and wise speech, grounded upon long experience; and containing, for the most part, some useful caveat. Such are, A close mouth catches no flies.—A high building, a low foundation.—A carrion kite will never be a good hawk.—A short horse is soon carried.—A man may love his house well, though he ride not on the ridge.—A false knave needs no broker.—Better to spare at brim, than at bottom.—A still tongue makes a wise head.—The scalded cat dreads cold water.—Let a man do *you* an injury, and *he* will never forgive *you*.—He that's ungrateful has no fault but one.—Fast bind, fast find.—A pin saved each day, makes ten pence in a year.—Take care of the pence, and the pounds will take care of themselves.—The rolling stone gathers no moss.—Three removes are as bad as a fire, &c. &c. &c.

**PROVERBS** (Book of), a canonical book of the Old Testament, containing a part of the proverbs of Solomon, the son of David, king of Israel. The first twenty-four chapters are acknowledged to be the genuine work of that prince; the next five chapters are a collection of several of his proverbs, made by order of king Hezekiah; and the two last seem to have

## PRO

been added, though belonging to different and unknown authors, Agur the son of Jakeh, and king Lemuel. In this excellent book are contained rules for the conduct of all conditions of life; for kings, courtiers, masters, servants, fathers, mothers, children, &c.

**PROVERBIAL.** *a.* (*proverbial*, French.)

1. Mentioned in a proverb (*Temple*). 2. Resembling a proverb; suitable to a proverb (*Brown*). 3. Comprised in a proverb (*Pope*).

**PROVERBIALLY.** *ad.* In a proverb (*Brown*).

**TO PROVIDE.** *v. a.* (*provideo*, Latin.) 1. To procure beforehand; to get ready; to prepare (*Milton*). 2. To furnish; to supply (*Bacon*). 3. To stipulate; to make a conditional limitation. 4. *To PROVIDE against.* To take measures for contracting or escaping any ill (*Hale*). 5. *To PROVIDE for.* To take care of beforehand (*Shakspeare*).

**PROVIDED that.** Upon these terms; this stipulation being made (*L'Estrange*).

**PROVIDENCE.** *s.* (*providentia*, Latin.) 1. Foresight; timely care; forecast; the act of providing (*Sidney*). 2. The care of God over created beings; divine superintendence (*Raleigh*). 3. Prudence; frugality; reasonable and moderate care of expense (*Dryden*).

**PROVIDENCE** in the second of the above acceptations has been acknowledged by the majority of men in all ages. Every altar that is erected, every prayer and every sacrifice that is offered up, affords a proof of this belief. So fully have men been convinced of the sincerity of each other's faith upon this subject, that in one form, that of an appeal to the Divine Ruler of the world, by the solemnity of an oath, they have introduced it both into the most ordinary and the most important business of life.

This universal conviction of men of all degrees of knowledge, from the most profound philosopher to the rudest barbarian, is probably to be traced to some primæval tradition, never totally effaced from any nation under heaven. The truth itself, however, is susceptible of the most complete proof from principles of science. If the world had a beginning, it may obviously have an end, and can be continued in existence only by the constant energy of that power by which it was at first created. He therefore who acknowledges a creation and denies a providence, involves himself in this palpable contradiction—"that a system, which of itself had not an original and momentary existence, may yet of itself have a perpetual existence; or that a being which cannot of itself exist for a second of time, may yet, of itself, exist for thousands of years!"

Simplicius argues thus for a providence: if God do not look to the affairs of the world, it is either because he cannot, or will not; but the first is absurd, since to govern cannot be difficult, where to create was easy; and the latter is both absurd and blasphemous.

The sentiments of Cicero are likewise very precise and pertinent to this purpose: he thinks it impossible for one who duly considers the

## PRO

innumerable objects of the universe, and their invariable order and beauty, to entertain the least doubt but that there is some efficient cause who presides over and directs the mighty fabric! Nay he lays it down as a fundamental principle of all societies, that there is a divine providence which directs all events, observes the actions of mankind, whether good or bad, discerns the very intentions of the heart, and will certainly make a difference between good men and the wicked.

Some admirable arguments in favour of what is usually called a particular providence, are given in Wollaston's *Religion of Nature Delineated*; they are transcribed by Dr. Gregory in his essay on the same subject in his *Letters on the Christian Religion*. A very excellent work on Providence was written by Char-nock.

PROVIDENCE, one of the Bahama islands, and the best of those planted by the English. It was taken by the Spaniards in 1782, but retaken the next year. The chief town is Nassau. Lon. 77. 20 W. Lat. 25. 3 N.

PROVIDENCE, an island in the Atlantic, which the bucaniers fortified, but afterward abandoned. It is 150 miles E. of the coast of Nicaragua. Lon. 80. 44 W. Lat. 13. 25 N.

PROVIDENCE, a river that rises in the state of Massachusetts, and waters the town of Providence, whence it is navigable for ships to Narraganset bay, which it enters on the W. side of Rhode island.

PROVIDENCE, the oldest town of the state of Rhode island, chief of a county of its name, and the semi-capital of the state. It has several manufactures, and a large foreign and inland trade. Here are six edifices for public worship; a handsome court-house, in which is a library for the use of the town and county; and a flourishing seminary, called Rhode Island College. Providence is seated on both sides of the river of the same name, 30 miles N.W. of Newport. Lon. 71. 26 W. Lat. 41. 51 N.

PROVIDENT. *a.* (*providens*, Lat.) Forecasting; cautious; prudent with respect to futurity (*Waller*).

PROVIDENTIAL. *a.* (from *providence*.) Effected by providence; referrible to providence (*Woodward*).

PROVIDENTIALLY. *a.* (from *providential*.) By the care of providence (*Addison*).

PROVIDENTLY. *ad.* (from *provident*.) With foresight; with wise precaution (*Boyle*).

PROVIDER. *s.* (from *provide*.) He who provides or procures (*Shakspeare*).

PROVINCE. *s.* (*province*, Fr. *provincia*, Latin.) 1. A conquered country; a country governed by a delegate (*Temple*). 2. The proper office or business of any one (*Otway*). 3. A region; a tract (*Watts*).

PROVINCE, in Roman antiquity, a country of considerable extent, which, upon being entirely reduced under the Roman dominion, was new-modelled according to the pleasure of the conquerors, and subjected to the command

## PRO

of annual governors, sent from Rome; being commonly obliged to pay such taxes and contributions as the senate thought fit to demand. Of these countries, that part of France next the Alps was one, and still retains the name of Provence. Nicod derives the word *a procul vivendo*, living afar off; but it is better deduced from *pro* and *vinco*, I overcome.

PROVINCE, in geography, a division of a kingdom or state, comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction. The church distinguishes its provinces by archbishoprics; in which sense, England is divided into two provinces, Canterbury and York.

PROVINCIAL. *a.* (*provincial*, French.) 1. Relating to a province (*Shakspeare*). 2. Appendant to the principal country (*Brown*). 3. Not of the mother country; rude; unpolished (*Dryden*). 4. Belonging only to an archbishop's jurisdiction; not oecumenical (*Ayliffe*).

PROVINCIAL. *s.* (*provincial*, French, from *province*.) A spiritual governour (*Stillingfleet*).

To PROVINCIATE. *v. a.* (from *province*.) To turn to a province: not in use (*Howel*).

PROVINCETOWN, a town of Massachusetts, in Barnstable county, situate on the hook of Cape Cod. Its harbour is one of the best in the state, and was the first port entered by the English, in 1620, when they came to settle in New England. The houses are only one story high, and set upon piles, that the driving sands may pass under them. The inhabitants are wholly dependent on Boston, and the towns in the vicinity, for every vegetable production. It is 50 miles E.S.E. of Boston.

To PROVINCE. *v. n.* (*provigner*, Fr.) To lay a stock or branch of a vine in the ground to take root for more increase.

PROVISION. *s.* (*provision*, French; *provisio*, Latin.) 1. The act of providing beforehand (*Sidney*). 2. Measures taken beforehand (*Tillotson*). 3. Accumulation of stores beforehand; stock collected (*Knolles*). 4. Victuals; food; provender (*Clarendon*). 5. Terms settled; care taken (*Davies*).

PROVISIONAL. *a.* (*provisional*, French; from *provision*.) Temporally established; provided for present need (*Ayliffe*).

PROVISIONALLY. *ad.* (from *provisional*.) By way of provision (*Locke*).

PROVISO. *s.* (Latin.) Stipulation; caution; provisional condition (*Spenser*).

PROVOCACTION. *s.* (*provocatio*, Latin.) 1. An act or cause by which anger is raised (*Smith*). 2. An appeal to a judge (*Ayliffe*).

PROVOCATIVE. *s.* (from *provoke*.) Any thing which revives a decayed or cloyed appetite (*Addison*).

PROVOCATIVENESS. *s.* (from *provocative*.) The quality of being provocative.

To PROVOKE. *v. a.* (*provoco*, Latin.) 1. To rouse; to excite by something offensive;

to awake (*Dryden*). 2. To anger; to enrage; to offend; to incense (*Clarendon*). 3. To cause; to promote (*Arbuthnot*). 4. To challenge (*Dryden*). 5. To induce by motive; to move; to incite (*Burnet*).

**TO PROVO'KE.** *v. n.* 1. To appeal. A latinism (*Dryden*). 2. To produce anger (*Taylor*).

**PROVO'KER.** *s.* (from *provoke*.) 1. One that raises anger (*Gov. of the Tongue*). 2. Causer; promoter (*Shakspeare*).

**PROVO'KINGLY.** *ad.* (from *provoking*.) In such a manner as to raise anger (*Decay of Piety*).

**PRO'VOST.** *s.* (*pfapart*, Saxon.) 1. The chief of any body: as, the provost of a college (*Fell*). 2. The executioner of an army (*Hayward*).

**PRO'VOST MARSHAL**, an officer of the king's navy, who has charge of the king's prisoners taken at sea.

**PROVOST**, or **PREVOT**, in the king's stables: his office is to attend at court, and hold the king's stirrup, when he mounts his horse, &c. There are four provosts of this kind, each of whom attends in his turn monthly.

**PRO'VOSTSHIP.** *s.* (from *provost*.) The office of a provost (*Hakewill*).

**PROW.** *s.* (*proue*, Fr. *prora*, Lat.) The head or forepart of a ship (*Peacham*).

**PROW.** *a.* Valiant (*Spenser*).

**PRO'WESS.** *s.* (*prouesse*, Fr.) Bravery; valour; military gallantry (*Sidney*).

**PRO'WEST.** *a.* (from *prow*, adjective.) 1. Bravest; most valiant (*Spenser*). 2. Brave; valiant. (from *prowess*.) (*Milton*).

**TO PROWL.** *v. a.* To rove over (*Sidney*).

**TO PROWL.** *v. n.* To wander for prey; to prey; to plunder (*Tusser*).

**PRO'WLER.** *s.* (from *prowl*.) One that roves about for prey (*Thomson*).

**PROXIMATE.** *a.* (*proximus*, Lat.) Next in the series of ratiocination; near and immediate (*Burnet*).

**PROXIMATE CAUSE.** *Causa proxima.* The proximate cause of a disease may be said to be in reality the disease itself. All proximate causes are either diseased actions of simple fibres, or an altered state of the fluids.

**PROXIMATELY.** *ad.* (from *proximate*.) Immediately; without intervention (*Bentley*).

**PROXIME.** *a.* (*proximus*, Latin.) Next; immediate (*Watts*).

**PROXIMITY.** *s.* (*proximitas*, Lat.) Nearness (*Hayward*).

**PROXY.** *s.* (By contraction from *procuration*.) 1. The agency of another. 2. The substitution of another; the agency of a substitute (*South*). 3. The person substituted or deputed (*L'Estrange*).

**PRUCE.** *s.* Prussian leather (*Dryden*).

**PRUDE.** *s.* (*prude*, Fr.) A woman over-nice and scrupulous, and with false affectation (*Swift*).

**PRUDENCE.** *s.* (*prudence*, French; *prudentia*, Latin.) Wisdom applied to practice (*Hale*).

**PRUDENT.** *a.* (*prudent*, Fr. *prudens*,

Lat.) 1. Practically wise (*Milton*). 2. Fore-seeing by natural instinct (*Milton*).

**PRUDENTIAL.** *a.* (from *prudent*.) Eligible on principles of prudence (*Rogers*).

**PRUDENTIALS.** *s.* Maxims of prudence or practical wisdom (*Watts*).

**PRUDENTIALITY.** *s.* (from *prudential*.) Eligibility on principles of prudence.

**PRUDENTIALLY.** *ad.* (from *prudential*.) According to the rules of prudence (*South*).

**PRUDENTIUS** (Quintus Aurelius), a Spaniard, and christian poet, born in 1348. He was lawyer, judge, and soldier, before he betook himself to poetry, in which he is not greatly admired for his versification. His works were printed at Amsterdam by Daniel Elzevir, in 1667, and again at Paris in 1687.

**PRUDENTLY.** *ad.* (from *prudent*.) Discreetly; judiciously (*Bacon*).

**PRUDERY.** *s.* (from *prude*.) Overmuch nicety in conduct.

**PRU'DISH.** *a.* (from *prude*.) Affectedly grave.

**PRUINOUS**, in natural history, covered with a kind of frosty mealliness.

**PRUNE**, in botany. See **PLUM** and **PRUNUS**.

**TO PRUNE.** *v. a.* 1. To lop; to divest trees of their superfluities (*Davies*). 2. To clear from excrescences; to trim (*Bacon*).

**TO PRUNE.** *v. n.* To dress; to prink. A ludicrous word (*Dryden*).

**PRUNELLA.** Self-heal. In botany, a genus of the class didynamia, order gymnospermia. Filaments forked; one point bearing the anthers on its lip; stigma cloven. Three species—European plants; one, *P. vulgaris*, found wild in our own pastures.

**PRUNELLA** (Sal), in pharmacy, a preparation of purified saltpetre, called also crystal mineral, made in this manner: having melted any quantity of saltpetre, cast a little flower of sulphur upon it, and when that is burnt throw on more; and continue to do so till the nitre flow as clear as rock-water. Then with a clean iron or brass ladle take it out, and, putting it into moulds till coagulated, preserve it for use.

**PRUNELLO.** *s.* 1. A kind of stuff of which the clergymen's gowns are made (*Pope*). 2. A kind of plum (*Ainsworth*).

**PRU'NER.** *s.* (from *prune*.) One that crops trees (*Denham*).

**PRUNIFEROUS.** *a.* (*prunum* and *fero*, Latin.) Plum-bearing.

**PRUNING**, in gardening the operation of lopping from wall-fruit trees their superfluous branches, so that every branch and part of a branch may be fully exposed to the rays of the sun; and the root be neither exhausted by barren shoots, nor have more fruit to supply with nutriment than it can render perfect.

Of this "master work of gardening," it has been said, "that gentlemen prune too little, and gardeners too much;" these extremes are to be avoided, as attended with peculiar evils, equally mischievous: wall-trees are presently spoiled by either practice. If they are too full of wood, the shoots

# PRUNING.

and fruits cannot be properly ripened : and if they are too thin (the greater evil of the two,) the consequence of the cutting that has made them so, is the production of wood rather than fruit ; forcing out shoots, where otherwise blossom-buds would have been formed. The designation of trees to a wall (from the superabundant heat) necessarily occasions cutting, and on the skilful use of the knife much depends.

Every one who has wall-trees cannot keep a professed gardener ; nor is every one who calls himself so qualified to prune. It is a great mortification to a man who wishes to see his trees in order, not to be able to procure an operator to attend them ; let him then resolve to learn the art himself, and the ability will be very gratifying to him.

As many words must be used on this article of pruning, for the sake of order, the business of managing wall-trees may be, 1. Concerning the form. 2. The health. 3. The fruitfulness of them.

1. As to the form, or general appearances of the wall-trees. If a tree is young and newly planted, the first thing is to head it down, by cutting off (if it is a nectarine, peach, or apricot) all the shoots, and the stem itself, down to a few eyes, that the lower part of the wall may be furnished with new and strong wood. Make the cut sloping, and behind the tree, taking care (by placing the foot on the root, and the left hand on the stem) not to disturb the tree by the pull of the knife. Plaster the part with a bit of cow-dung, clay, or stiff earth. It is evident from this that maiden stocks are the best to plant.

The heading down is to be made so as to leave two or three eyes, or four if a high wall, on each side of the stem, from which shoots will come properly placed for training. The number of eyes may be also according to the strength of the tree, and its roots. If there are not two well-placed eyes on each side of the stem, two shoots, thus situated, may be left, cutting them short to two or three eyes each. Eyes or shoots behind or before, consider as of no use, and let them be early displaced by rubbing or cutting. This work is to be performed in spring, when the tree is putting forth shoots ; i.e. about the beginning of April.

If towards the end of May there should be wanting shoots on either side the tree, having perhaps only one put forth where two were expected, this one shoot should be cut, or pinched down, to two or three eyes ; and before summer is over there will be found good shoots from them, and thus a proper head be obtained. This work of shortening shoots of the year may be done any time before midsummer ; but in this case, all ill-placed or superfluous growths must be rubbed off as soon as seen, that those to be reserved may be the stronger, receiving more nourishment.

As the lateral shoots grow, let them be timely nailed to the wall, close, straight, and equidistant, but use no force. If they are quite well placed, they will need no bending ; but sometimes shoots must be laid in which are not perfectly so. Lay in as many good moderate-sized shoots as may be throughout the summer, for choice at winter pruning, yet do not crowd the tree. As the shoots proceed in length, nail them to the wall, that no material dangling of them may be seen ; but avoid using too many shreds.

In the formation of a tree, keep each side as nearly as can be equal in wood ; and the shoots inclining downwards, which is a mode of training necessary to fill the lower part of the wall (none

of which should be lost), and to check the too free motion of the sap, which wall-trees are liable to from their warm situation and continual cutting. All the branches should have an horizontal tendency, though the upper cannot have it so much as the lower ones. Those that are perpendicular, or nearly so, mount the wall too fast, and run away with the food that should pass to the horizontals ; which being impoverished by the vigorous middle branches, gradually become too weak to extend themselves, and nourish the fruit. The pruner, therefore, must be content to have some of the wall, over the middle of the tree, unoccupied ; or, at least, suffer none but weak or very moderate shoots to find a place there.

The idea of a well-formed tree is somewhat represented by the ribs of a spread fan, or the fingers of the hand extended. Regularity is allowed to be so necessary to the beauty of a wall-tree, that some have even drawn lines for a guide to train by ; but nature (ever free and easy) will not submit to so much formality, and such a perfect disposition of the branches is not necessary. A tree may be regular without being linear, and the proper useful shoots are not to be sacrificed to a fanciful precision. Though crossing of branches is against rule, yet cases may happen (as in want of wood or fruit) where even this awkwardness may be permitted. The object is fruit ; and to obtain this end, form must sometimes give place.

All foreright and back shoots, and other useless wood, should be displaced in time, for they exhaust the strength of the tree to no purpose, and occasion a rude appearance. It is a very expeditious method to displace superfluous young shoots, by pushing or breaking them off ; but when they get woody it is apt to tear the bark, and in this case the knife must be used : the better way is to disbud by rubbing ; yet a young luxuriant tree should be suffered to grow a little wild to spend the sap. There is one evil, however, attending on disbudding, and rubbing off young forerights, that some fruit spurs are thus lost ; for apricots are apt to bear on little short shoots of from half an inch to an inch (or more), and there are peaches which do the same ; so that it is a rule with some pruners to wait to distinguish spurs from shoots, and then to use the knife, yet use it as little as may be in summer.

In regulating a tree at any time, begin at the bottom and middle, and work the way orderly upward and outward. Never shorten in summer (which would produce fresh shoots), except a forward shoot where wood may be wanting ; but where the tree is really too thick, cut clean out what may be spared. None of the shoots produced after midsummer should be nailed in, except where wood is wanting to fill a naked place. They never bear fruit.

2. The health of wall-trees is greatly provided for by observing the directions already given concerning their form ; for if observed, each shoot will have the proper benefit of sun and air, to concoct its juices and prepare it for fruiting.

It injures a tender shoot when it presses hard against a nail. If the hammer strikes a shoot, and bruises the bark, it often spoils if not kills it, by the part cankering. The shreds may be too tight, so that the shoot cannot properly swell ; and if shreds are too broad and too numerous, they are apt to occasion sickness, and prove a harbour for insects and filth : let the number be lessened at all opportunities. A slip of the knife may wound a neighbouring branch, and make it gum,

## PRUNING.

canker, or die. It will require care, and some practice, to avoid this accident; and in order to it, keep the point of the knife sharp, and mind the position of it when cutting. Cut close and sloping behind the eye; neither so near as to injure it, nor so wide as to leave a stub.

The bending of a branch much is a violence to be avoided; so that every shoot should be kept from the first in the direction it is to grow in.

Luxuriant wood must be particularly attended to, to get rid of it in time, before it has robbed the weaker branches too much. That is luxuriant wood which, according to the general habit of the tree, is much larger than the rest; for a shoot that is deemed luxuriant in one tree may not be so in another. If strong wood, that is not very luxuriant, happens to be at the bottom of the tree, so that it can be trained quite horizontally, it may often be used to good purpose, as this position checks the sap. A luxuriant shoot may be kept in summer where it is not designed to retain it, merely to cut it down at winter-pruning to two or three eyes, for getting wood where wanted the next year; or this shortening may take place in June, to have new shoots the present year. Luxuriant shoots may be sometimes retained for a time, merely as waste pipes.

All diseased, damaged, very weak, or worn out branches (as they occur), should be cut out, to make way for better; but if a tree is generally diseased, some caution must be used not to cut out too much at once, if there is any hope of restoring it. A very old tree, or a young one that does not thrive, may be cut a great deal; but prune it so as to have a general sprinkling of the best of the branches, and keep short lengths of an eye or two of the weaker ones, in a sort of alternate order.

Young trees are very apt to decline, and sometimes die, if suffered to overbear themselves the first year or two of fruiting. The remedy is obvious, and should resolutely be applied.

A weak tree is helped much by training it more erectly than usual, as less check is thus given to the sap, and so the shoots are more likely to swell: such a tree should be kept thin of branches, and always pruned early in autumn, keeping the top free from such wood as is stronger than that which is in general below, and all the shoots shorter than usual.

Old decaying trees should be lessened a little every year, and constantly watched, to observe where young and strong shoots are putting out below, in order to cut down to them; and though the time for doing this is commonly at autumn or winter pruning, yet it may be best done in summer, as the shoots would thrive the better; observing to put some grafting-clay or cow-dung to the part, to prevent gumming, which summer pruning is apt to occasion. A judicious pruner may bring the oldest and most ill-conditioned tree to a healthy and bearing state if all is but right at the root, in having a good soil about it.

Keep all wall-trees clean, and particularly weak ones, from moss, cobwebs, or other filth; and attend to insects, snails, caterpillars, and smother flies. Any bark that is decayed by cracks, &c. must be cleared away to the quick, either by rubbing, or the knife, as filth and insects are apt particularly to gather there: wipe the part clean with sponge and soap.

Consider the soil about an unthrifty tree, and if it is thought bad, improve it by moving away

as much of the old as conveniently can be done. The roots may be laid carefully quite bare, and examined, in order to cut off decayed or cankered parts, and to apply immediately to them some fine and good fresh earth, with a little thorough-rotten dung in it, and a sprinkling of soot or wood ashes. Hog-dung applied fresh is said to have a peculiar efficacy in recovering weak trees; and cow-dung may reasonably be expected to do good if the soil is a warm or hungry one; and if not so, the hog-dung is not so proper, as it is a cold dressing. If the soil is a strong one, a compost of fowl's or sheep's dung, lime, with any fresh light earth, (one part of each of the former, and three of the latter, mixed with the soil that is taken off,) will be a proper manure, to which a little sharp sand may be added. All these applications should be made late in autumn, or early in spring.

The constitution of a tree is sometimes naturally barren; or the soil that the roots have got into may be so deleterious that no pains or perseverance will avail any thing; but continuing fruitless and sickly, admonishes the owner to take it up and try another plant, rectifying the soil thoroughly if the evil is thought to arise there. The smother-fly sometimes repeatedly attacks the same tree, which is a sign of inherent weakness, for the juices of a sickly tree are sweeter than those of a sound one, and so more liable to such attacks. Sometimes a tree of this kind, when removed to a good soil, and pruned greatly down, does very well. A soil too rich of dung often occasions trees to be blighted, and the remedy is to impoverish it with a sharp sand.

In order to health and strength, a tree must not be kept too full during summer, as it prevents the proper ripening of the wood, and makes the shoots long-jointed. If more than one shoot proceeds from the same eye, reserve only the strongest and best-situated. A crowded tree cannot be healthy, and it becomes both lodging and food for insects. The blossom-buds of a tree being always formed the year before, they will be few and weak in a thicket of leaves, as debared of the necessary sun and air; but in order to avoid an over-fullness, do not make any great amputations in summer.

In clearing a tree of superabundant wood, take care not to cut off the leading shoot of a branch. All shoots after midsummer should be displaced as they arise, except where wanted to fill up a vacancy. In a too vigorous tree, the midsummer shoots may be left for a while on those branches that are to be cut out at winter pruning, as cutting such trees in summer is to be avoided as much as possible; so that a little rudeness in a luxuriant tree may be permitted as a necessary evil, provided it becomes not too shady or unsightly. Watering wall trees with an engine smartly on a summer's evening is conducive to their health, and frees them from insects.

3. The fruitfulness of wall-trees (the ultimate object of planting and training them) comes now to be spoken of. Their proper form and health being good, the foundation is laid, but several things are yet to be done to obtain the end proposed; and this chiefly regards the principal cutting, or what is called winter or spring pruning.

If trees have been planted far enough asunder, it is a happy circumstance, as the proper horizontal form, and the open middle, may be preserved. The longer the horizontals are, the more necessary it is to be careful to suffer none but weak branches in the centre uprightly. If trees are

## PRUNING.

confined as to length of wall, they of course take a more erect form, but still strong wood should not mount just in the middle.

A tree is to be thinned of damaged, unpromising, and ill-placed shoots, and of woody branches that are decaying or reach far without fruitful shoots on them, and always some of the old wood should be cut out where there is young to follow or supply its place. Of the fair and well-placed shoots also, the superabundance is to be taken away, so as generally to leave the good ones at four, five, or six inches asunder, according to the size of the wood and fruit.

Luxuriant wood, *i. e.* those shoots that are gigantic, must be taken out from the rest, as they would impoverish the good, and destroy the weak branches, and are never fruitful; but if a tree is generally luxuriant it must be borne with; and the less it is cut, comparatively speaking, the better. Such a tree, after a few years, may come to bear well; and when it begins to shoot moderately, some of the largest wood may be taken out each year, or shortened down to two or three eyes, and so brought into order. The more horizontally free-shooting trees are trained, the better, as the bending of the shoots checks the sap.

As the pruner is to begin below, and towards the stem, so the object in thinning must be to prefer and to leave those shoots that are placed lowest on the branches, that so the tree may be furnished towards the centre. See that those left are sound, and not too weak or over-strong, for the moderate shoots generally bear best. Weak shoots are always more fruitful than strong ones; and if they are furnished with fair blossoms, should be kept where a tree is full of wood, and even preferred to moderate ones on a very flourishing tree.

The next object is, to furnish a tree. In order to this, the thinning of old wood, young being ready (or easily to be procured) to follow, has already been mentioned; but the principal step is the shortening of the shoots, which occasions them to throw out below the cut, for future use. If they were not to be shortened, the tree would presently extend a great way, bearing chiefly at the extremities; and all over the middle it would be very thin of fruit, and thus a great part of the wall lost.

The mode of bearing in peaches, nectarines, and apricots, is on the last year's wood; which makes it necessary to shorten, in order to a certain supply of shoots for bearing the next year, and thus to have succession-wood in every part of the tree.

The rule for shortening is this: Consider the strength of the tree; and the more vigorous the shoots are, cut off the less. If a luxuriant tree was to have its shoots much shortened, it would throw out nothing but wood; and if a weak tree was not pretty much cut, it would not have strength to bear. From vigorous shoots one-fourth may be cut off; from middling ones one-third; and from weak ones one-half.

In shortening, make the cut at a leading shoot-bud, which is known by having a blossom-bud on the side of it, or, which is better, one on each side. Blossom-buds are rounder and fuller than leaf-buds, and are discernible even at the fall of the leaf, and plainly seen early in the spring. It is desirable to make the cut at twin blossoms, yet as this cannot always be done, the due proportion of length must generally determine. It often happens, that the blossom-buds are chiefly, and sometimes all, at the end of the shoot; but still it should

be shortened if it is at all long. Never cut where there is only a blossom-bud; and prefer those shoots that are shortest-jointed, and have the blossoms most in the middle. The shoots that lie well and are fruitful or healthy, and but a few inches long, may be left whole. Always contrive to have a good leader at the end of every principal branch.

Young trees (as of the first year of branching) should have the lower shoots left longer in proportion, and the upper shorter, in order to form the tree better to the filling of the wall: the lower shoots may have three or four eyes more than the upper.

In furnishing a tree, consider where it wants wood, and cut the nearest unbearing branch (or if necessary, a bearing one) down to one, two, or more eyes, according to the number of shoots desired, for in such close shortening, a shoot will come from each eye. With a view to wood for filling up a naked place, a shoot formed after midsummer may be thus shortened; though the general rule is, to displace all such late shoots as useless, the dependence for blossoms being on the early-formed shoots.

The time for the principal, or winter pruning, is by some gardeners held indifferent, if the weather is mild at the time; but a moderate winter's day is often quickly followed by a severe frost, which may hurt the eye and blossom next the cut. The best time is February, if it is mild, or as soon after as possible; for when the blossom-buds get swelled, they are apt to be knocked off by a little touch or jar of the hammer.

Apricots should not be so much shortened as peaches, nor do they so well endure the knife. Shoots of the apricot, if under a foot, may be left uncut, if there is room. The spurs of apricots should be spared, if not too long or numerous, for they bear well, and continue for years. Some sorts of peaches are also apt to put out fruit-spurs, and must be managed accordingly.

Vines require frequent attention, as to pruning and training; but all will avail little if they have not a warm soil and full sun, or some accidental advantage, as being planted at the back of a warm chimney; and though they will grow and bear leaves any where, they will not fruit well in England without a favourable season, or hot summer.

Young new-planted vines should be pruned quite short for two or three years, that they may get strong. If the plant has a weak root, not above one shoot ought to grow the first year, which should be cut down in autumn, or to two or three eyes.

The best time for the principal, or winter pruning of vines, is as soon as the fruit is off, or the leaves falling. November does very well, and if this month passes, February should be adopted rather than quite in the winter. Late in the spring they are apt to bleed by cutting, which greatly weakens them.

The mode of bearing in vines is only on shoots of the present year, proceeding from year-old wood. The rule, therefore, at winter pruning is, to reserve those shoots of the year that are best situated as to room, for training of those shoots that are to come from them, which will be almost one from every eye. Make choice of those that are placed most towards the middle, or stem of the vine, that all the wall may be covered with bearing wood; and every year cut some old wood

## PRUNING.

out that reaches far, to make room for younger to follow.

The shortening of the shoots should be according to their strength, and the space there is for training those shoots that will be produced, which always grow very long. If there is room, three, four, or five eyes may be left; but not more to any shoot, except it is desirable to extend some shoot to a distance to fill up a particular space: and then eight or nine eyes may be left, which being repeated again another year, and so on, a vine will soon reach far.

Sometimes vines are trained on low walls by a long-extended horizontal branch, a few inches from the ground, as a mother-bearer. Those shoots that come from this horizontal are to be trained perpendicularly, and cut down to one or two eyes every year, that they may not encroach too fast on the space above them. If the vine is confined to a narrow but lofty space, it is to be trained to an extended perpendicular mother-bearer, having short lateral shoots pruned down to a single eye, or at most two. The management of vines requires severe cutting, that they may not be too full in the summer, for they put out a great deal of wood, and extend their shoots to a great length; and therefore the young pruner must resolve to cut out enough.

An alternate mode of pruning vines is practised by some, one shoot short, and another long, *i. e.* one with two eyes, and another with four or five. Severe cutting does not hurt vines, and make them unfruitful, as it does other trees; and therefore, where short of room, they may be pruned down to a single bud, as the case requires.

The summer management of vines must be carefully attended to. As soon as the young shoots can be nailed to the wall, let them not be neglected; but remember they are very tender, and will not bear much bending: train in only the well-placed shoots, rubbing or breaking off the others. The embryo fruit is soon seen in the bosom of the shoot; and those thus furnished are of course to be laid in, as many as can be found room for, in preference to those shoots that are barren; which nevertheless should also be trained, if they are strong and well placed, and there is space for them. Rub off all shoots from old wood, except any tolerable one that proceeds from a part where wood is wanting to fill up some vacant space. If two shoots proceed from one eye, displace the weakest, or the outermost if they are both alike, and the fruit should not direct otherwise. Vines grow rapidly; and must be nailed to the wall, from time to time, as they proceed, that there may be no rude dangling, which would not only have a slovenly appearance, but in several respects be injurious.

The stopping of the shoots is to take place, both as to time and measure, according to the strength and situation of them, or whether fruitful or barren. Those weak shoots that have fruit, and are rather ill placed, or confined for room, may be stopped at the second, or even first, joint above the fruit, early in the summer; but those shoots that are strong and have room to grow should not be stopped till they are in flower (in July), and at the third or fourth joint above the fruit. In shortening the shoots of the vine, do it about half an inch above an eye, sloping behind a plump and sound one. The barren shoots are to be trained at full length, and not stopped at all if there is room for them, or, at least, but a little shortened towards autumn, as in August, because they would

put out a number of useless and strong side-shoots if cut before.

The side-shoots, *i. e.* those little ones put out by the eyes that are formed for next year, are commonly directed to be immediately displaced by rubbing off, as soon as they appear; and if the vine is large, and the shoots slender, it is very proper; but if otherwise, their being left to grow awhile (so as not to get too rude and crowding) is rather an advantage, in detaining the sap from pushing the shoots out immoderately long; and when these are taken off, the lower eye of each may be left with the same view. But the side shoot that proceeds from the top of each shortened branch should be left on, and when it gets long, then shortened down to an eye or two.

In order to fruitfulness, vines will need dressing with some sort of manure; for though they grow in vineyard countries on rocky hills, and in very shallow soils, and have done so on some chalky, hot, gravelly hills in England, yet some warm manure they must generally have applied, or they will produce little good fruit.

Some people are very fond of exposing the fruit of the vine to the full sun, by stripping off leaves; but this should not be practised till the bunches have attained their proper size, needing only to be ripened, and even then but little should be done in this way. The loss of leaves is an injury to every plant, as it prevents the elaborating of the saccharine juices necessary to perfect the fruit.

Fig-trees are best pruned early in spring, as after an autumn cutting (if late) they are apt to die down. The mode of bearing in the fig is, that fruit chiefly comes the present year on the little shoots from wood of the preceding, and that towards the ends of the branches, which circumstances dictate the rules for pruning. Two-years-old wood will bear some, but older wood never.

The shoots, during summer, are to be laid in at full length, plentifully, as room will permit. The weak, ill-placed, or superabundant ones, cut clean out; yet rather break, or rub them off, in an early state of growth, for cutting branches or shoots in summer is apt to make them bleed as it is called, *i. e.* the sap run; when cut in autumn, the fig will sometimes bleed for a day, but if late-cut in spring, the oozing will continue perhaps a week.

At the principal pruning, the strongest and the closest-jointed shoots are to be preferred, and left about seven or eight inches asunder, without shortening. Let the spare shoots be cut out close and smooth, and as much of the old wood as may be: for the tree will increase too fast, and get too naked of bearing wood in the middle, if this is not freely done; and the essential point in the management of the fig-tree is (as indeed of all wall-trees) to have young wood all over it, and particularly in the middle, and towards the bottom. Wood is seldom wanted in a fig-tree; but where it is, the shortening of a shoot, properly situated (by taking off the leading bud, or cutting lower, as the case requires), is sure to produce it. Do this in April, as the best time.

When hard frosts are expected, strew some ashes and some litter over the roots of fig-trees. Mats should be nailed over their branches (first pulling off the figs), as the succulent nature of their wood makes them tender. These coverings are to remain till the frosts are judged to be over, and then let them be covered up at night, and not

## PRUNING.

by day, for a week or two, to harden them by degrees.

But fig-trees will mostly survive hard winters when in standards, without covering; and though shoots trained to a wall are tenderer, yet pea-baulm hung close among the branches (at the approach of sharp frosts) will preserve them. This sort of protection, as affording plenty of air, is by many good gardeners preferred to the more common practice of matting. But if mats were contrived to roll up and down, or kept a little distance from the tree, so as to give more or less air as the weather is, the health and fruitfulness of the tree would be better ensured, for too close (and, as it commonly happens in consequence, too long) covering is injurious to both. Fig-trees that have been close covered are often hurt by an early uncovering, and yet the spring air, as soon as possible, is desirable.

Pears being planted against a wall in autumn, should not be cut down till spring, when the head is to be reduced according to the goodness of the root, and so as to lay a proper foundation for covering the wall.

The mode of bearing in pear-trees is on short spurs, which appear first towards the ends, and then form themselves all along the branches, which do not produce blossoms for three or four years from planting, and sometimes (according to the sort, or perhaps soil) for several years more. When they are come to fruiting, some pears bear pretty much on year-old wood, some on two, others on three. The same branches continue to bear on spurs from year to year, and most when five or six years old; but as in course of time the branches may become diseased and barren, and not produce so fine fruit as younger wood, it is always proper to procure a succession of young bearers, as the opportunity of good shoots offer, cutting out old wood.

The time for general or winter pruning of pear-trees ought to be November, as the blossoms are then very discernible, and at spring pruning they get so turgid and tender, that almost the least touch knocks them off, or even the jarring of the tree.

Apples are sometimes planted against walls, and what has been said of pruning and managing pears is applicable to them; the branches, however, may be laid in somewhat closer, as they will not require so much room; yet they ought to have from twenty-five feet in length of a low wall, or on a high one something less.

Mulberries require good room, as their mode of bearing is mostly at the end of the trained shoots, which are therefore not to be shortened. Twenty or twenty-five feet should be allowed them, and a new-planted tree is to be headed down as directed for pears, &c. A succession of new wood must be always coming forward, and of course some old taken out, for the fruit is produced chiefly on year and two-year old wood; and as it comes on spurs, and also small shoots of the same year, the leaving short stubs (of moderate wood) in pruning, seems justified, though by some condemned.

Cherry-trees, if against a wall, should be trained at length, four or five inches asunder. The fruit comes from spurs all along the shoots, on one and two years old wood, which will continue to bear. In pruning, have an eye, however, to some fair shoots for successors to those that are getting diseased, or worn out. Some cut all superfluous shoots clean away, and others leave a sprinkling

of short stubs, which may be allowed; but let them not advance far foreright.

Plums of the finer sorts are often planted against walls, and deserve a good one. For the pruning of plum-trees, the directions given for cherries apply to them, only that the branches should be laid somewhat wider, *i. e.* at five or six inches, according to the sort, as free or less free in their growth.

Currants and gooseberries bear fruit upon young wood, and on little spurs of the old. Superfluous shoots are to be cut down to little stubs or spurs, about half an inch long, which will throw out fruit-shoots and spurs. The mother-branches of currants and gooseberries will last many years; but when good young wood can be brought in for principals, a renewal every three or four years is necessary to produce fine fruit.

The work of pruning espalier-trees is much the same as for wall-trees.

As trees planted for espalier training should be young, let great care be taken to set them off right at first, by regular shoots, full furnished immediately from the stem, which is effected by proper heading down. Apples, pears, plums, cherries, &c. in general, need not to be so much freed of all branches at planting, as peaches, nectarines, and apricots. There are, however, gardeners who prune down to the stem all sorts of wall and espalier trees, as peaches are.

The principle of pruning standard trees is the same, whether full, half, or dwarf standards; and the object is, to form a compact handsome round and open head, rather small than large, equal on all sides, with tolerably erect wood, capable (as far as the art of the pruner can go) of supporting the fruit without much bending. Perfect symmetry indeed is not necessary: but confusion of branches, weak and crossing, crowded and dangling, is to be prevented by pruning; for a proper use of the knife is capable of doing much towards the beauty and fruitfulness of standard trees. A little pruning of standards every year, and a general one every three or four years, to cut out what is decayed, and some of the older wood where a successful supply of young may be obtained to succeed, is the way to keep them in vigour, and have the best of fruit; for that which grows on old wood gets small and austere. To take off large branches, a thin broad chisel is proper; but if a saw is used, smooth the part with a knife.

Clear trees from moss, by scraping them with a long narrow-bladed blunt knife, on a bit of hard wood; and cut or rub off bits of decayed bark, in which insects are apt to breed, and wipe the part clean. Some use a scouring-brush, the long end-hairs of which are well adapted to clean the fork parts. A bit of hair cloth is also used for the purpose; and a finish is properly made to do the business well, with a brush and soap and water.

*Of pruning shrubs.*—Many shrubs are cultivated for their ornament, and some for their fruit; of the latter kind are raspberries and barberries.

Raspberries bear fruit on little side shoots of the present year, proceeding from stems of the last, and sometimes produce a little on those of the same year. To prune or dress the shrub, therefore, first cut out all the old bearers, whose wood dies; then cut out, close to the stool, all the new shoots, except three or four of the strongest, which may be carefully twisted from the bottom upwards, or tied together at the top, or if upright and strong, left to support themselves singly.

The barberry is a beautiful and somewhat large shrub, which should be suffered to grow with a full head, like a dwarf standard tree. It bears along the sides of both young and old wood, but chiefly towards the ends, and its branches should therefore not be shortened, except with a view to throw out wood. Keep the root free from suckers, and the stem from shoots in its lower part, and prune out weak, luxuriant, straggling, and crossing branches, forming it to a somewhat round head, which keep moderately open. Let the stem be freed from lower branches to the height of three, four, or five feet, according as the shrub may be desired to approach to a tree.

Flowering shrubs are of great variety, and the method of pruning them is to be determined according to the several modes of bearing, of which consider chiefly these; that is, whether they produce their flowers upon the last year's shoots or the present, on the ends or the sides of their branches. If a shrub bears on the last year's shoots, it is evident that it must be cut away no more than is necessary to keep it within bounds, open and handsome as to its form; in this case it is the business to cut clean out, or very low, what is to be spared. If a shrub bears on the present year's shoots, the old wood may and must be cut down freely, so however as to leave eyes enough for new shoots to proceed from, to make a sufficient head and show. If the shrub bears altogether or chiefly at its ends, no shortening must take place: but if some of the branches are too long, they may be either cut out, or quite low, leaving the shorter ones to bear. If the shrub bears along its sides, the shortening is of no consequence, and the desired form may be freely provided for at pleasure.

The season for pruning shrubs is generally the spring; but autumn is better, if not too near winter, as at this time sharp weather might occasion some of the sorts (as jasmines and honeysuckles) to die down. The time of flowering must in some measure direct the time of pruning. Shrubs that flower in winter (as the laurustinus) should be cut in spring. Those that flower in spring may be pruned immediately after their blow, or in summer. Those that flower in summer should be pruned in autumn; and those that flower in autumn should be pruned either soon after flowering, or in spring.

Be sure to take off in time, *i. e.* as soon as discovered, all suckers and over-strong shoots from shrubs; for by their luxuriancy they greatly impoverish the proper-sized branches, which are the fruitful ones, and such large sappy wood looks very unsightly.

The height of shrubs in certain situations is material, and to provide for this, the art of pruning is in a great measure competent. To keep them low, cutting down is of course necessary; but it will be well also to make the soil poor if too rich. To encourage them to mount, keep trimming off close the lower branches, and improve the ground by digging and dressing occasionally.

Roses bear upon shoots of the present year, and upon those formed after midsummer in the past year, but chiefly upon the former. Therefore they may, or rather should, be cut down low, leaving only three or four eyes to a shoot; except some of those short shoots formed the last year too late to blow then, leave whole. If rose-trees are not close pruned, they will be unable to support their flowers properly. Use a sharp knife, and cut close behind an eye or bud. Roses for forcing should be pruned in July and August.

Honeysuckles flower on shoots of the present year, and therefore whether trained to walls, or kept in bushes, should be also pruned close; but not so short in the latter case as the former, for those against walls should be cut down to an eye or two, and those in bushes to three or four eyes.

Sweetbriars flower on shoots of the present year, and therefore should be cut after the manner of honeysuckles. These shrubs (and most others) are seldom pruned down enough, so that in a few years they get very rambling and unsightly; but if kept compact, we have beauty as well as sweetness, to recompense our care. In all cases, a less number of fine flowers obtained by short and open pruning, is certainly preferable to many indifferent ones.

Lilacs bear their flowers at the ends of shoots of the last year, so of course at spring must not be shortened. If rambling and crowded, cut either clean out, or very low, what may be superfluous. If they need much reduction, let them be cut down as soon as (or somewhat before) they have got off flower.

To enter farther into the detail of shrubs would be inconsistent with our limits. The reader will find some directions occasionally under the separate articles, and will commonly act safely under the general directions above.

**PRUNINGHOOK. PRUNINGKNIFE. s.**  
A hook or knife used in lopping trees.

**PRUNUS.** Plum-tree. In botany, a genus of the class icosandria, order monogynia. Calyx inferior, five-cleft; petals five; drupe with a stone marked with slightly prominent seams. Thirty-one species; natives of Europe, Asia and America, six of our own country.

The following are the cultivated species:

1. *P. domestica.* Common plum-tree. This grows wild in our hedges with peduncles, mostly solitary: leaves lance-ovate, convolute when young, and unarmed branches, and gives birth to all the rich variety of our cultivated garden and orchard plum-trees, of which there are some hundreds.

2. *P. insititia.* Bullace-tree. Peduncles in pairs; leaves lance-ovate, convolute when young, villous underneath; branches ending in a spine. This also is common to our hedges; from twelve to fifteen feet high. It varies with black and white, or rather wax-coloured fruit; and also with a red, bitter, unpleasant fruit.

3. *P. spinosa.* Black-thorn. Sloe-tree. Peduncles solitary; leaves elliptic, lanceolate, pubescent underneath; fruit straight; branches spinous. Found also in our hedges and woods; and often very usefully employed in the formation of hedges.

Three sorts of plums, from the almost infinite variety of the plum-family, are ranked among the articles of the materia medica; they are all met with in the gardens of the country, but the shops are supplied with them moderately dried, from abroad. 1. The *pruna brig-nolensia*; the Brignole plum, or prune, brought from Brignole in Provence; it is of a reddish yellow colour, and has a very grateful, sweet, subacid taste. 2. The *pruna gallica*, the common or French prune. The *pruna damascena*, or damson. (See DAMSON.) All these fruits possess the same general qualities

## PRUNUS.

as the other summer fruits. The prunelloes, in which the sweetness has a greater mixture of acidity than in the other sorts, are used as mild refrigerants in fevers and other hot indispositions. The French prunes and damsons are the most emollient and laxative; they are often taken by themselves to gently move the belly, where there is a tendency to inflammations. Decoctions of them afford a useful basis for laxative or purgative mixtures, and the pulp in substance for electuaries.

4. *P. Armeniaca*. Apricot. Flowers sessile; leaves somewhat hearted. It is a native of the Levant; and in cultivation yields a great multitude of varieties.

5. *P. cerasus*. Common cherry-tree. Umbels nearly sessile; leaves ovate-lanceolate, folded when young. An elegant as well as a most useful fruit-tree. It differs from the plum in having the stone nearly globular, with the kernel of the same shape. A native of Asia and Europe. Its varieties are too numerous to be detailed.

6. *P. avium*. Small-fruited cherry-tree. In some counties called merries. It often grows to a large sized tree, and is found wild in our own woods. It has two or three varieties.

7. *P. padus*. Common bird cherry-tree. Found also in our woods; rising to the height of ten or twelve feet, with a trunk of nine or ten inches in diameter. Sometimes called the cluster cherry-tree.

8. *P. rubra*. Cornish bird cherry-tree. More than twenty feet high, with branches shorter and closer than in the last; fruit larger, and red when ripe. It is found wild in Armenia.

9. *P. Virginiana*. Common American bird cherry-tree. Rises with a thick stem from ten to thirty feet high, dividing into many branches, with a dark purple bark. Fruit larger than in the preceding, black when ripe, and greedily devoured by birds. Wood beautifully veined with black and white, and bears a good polish. A native of Virginia and other parts of North America.

10. *P. Canadensis*. Canadian bird cherry-tree. Branches even; leaves slightly serrate, green on both sides. A native of North America.

11. *P. mahaleb*. Perfumed cherry-tree. A low, crooked tree; wood red, hard, sweet-scented; fruit black, yielding a bitter purple juice that stains, without being easily removed. A native of Austria. In Ray it is called rock-cherry.

12. *P. Caroliniana*. Ever-green bird cherry. Shrubby; not more than three feet high, with lateral branches, spreading on every side covered with a brown bark. A native of South Carolina.

13. *P. lauro-cerasus*. Common laurel. A wide-spreading shrub, with a smooth brown bark; flowers racemed, calyx ovate, petals white; filaments about eighteen; leaves ever-green, with two glands on the back above the petioles; fruit resembling a black cherry both

in its external and internal structure. A native of the Levant; flowers in April.

14. *P. Lusitanica*. Portugal laurel. Stem arborescent, rising upwards of twenty feet, branchy, with a shining purplish bark; leaves evergreen, bright; flowers in long bunches from the sides of the branches, white in colour; berries oval, pulpy, at first green, then red, and when ripe very dark purple; smaller than those of the last sort, and narrower at the end: flowers in June; and is one of the most beautiful evergreen shrubs we possess. A native of Portugal.

Plums are all propagated by budding or grafting upon stocks of the stoutest wild sorts. Budding answers best, as the incision is apt to throw forth a great deal of gum: the tree should be no more than one year's growth from the bud when transplanted; if beyond this it will be subject to canker, or at least produce only two or three luxuriant branches. If the tree be meant for walls, the whole management of planting and pruning will be the same as that for peaches.

Should the walls against which they are to be planted below, they must be placed thirty feet asunder, but if high, twenty feet will be sufficient, with an east or south-east aspect: the soil should be midway between one very moist and very dry.

Plums, with proper care, succeed very well as espaliers or standards, but the fruit will not be so rich. It is a common error to be too free with the knife in winter pruning, in which the extremities of all the branches are cut off; the consequence of this is, that there is a surplus of young shoots produced, and the fruit becomes small and impoverished.

Of the apricot there are several varieties which may be propagated by budding on plum-stocks. These trees may also be planted in October, against walls with an east or west aspect, in borders of fresh earth, from a pasture-ground; they may stand at the distances directed in the culture of the plum, and let the ground round the roots be covered with rotten dung, to keep out the frost. About the beginning of March you must cut off the head of the tree, and shorten it to about four or five eyes above the bud, so that the sloping side may be towards the wall, taking care not to disturb the root. In spring, if the weather be dry, the trees must be gently refreshed with water, and some turf or other mulch should be laid round their roots. Let the new branches be nailed to the wall in an horizontal position, and such shoots as are produced fore-right must be entirely displaced; at Michaelmas unnailed the branches, and shorten them in proportion to their strength; after which nail them as horizontally as possible. The second and third year the trees may have nearly the same management.

There are several varieties of the cherry-tree usually cultivated in fruit-gardens. They are all propagated by binding or grafting the several kinds into stocks of the black or wild red cherries, which are strong shooters, and of a longer duration than any of the garden kinds.

The stones of these two kinds are sown in a bed of light sandy earth in autumn, and the young stocks produced from them are to remain where they rise till the second autumn after their sowing, when in October they should be planted out into a rich earth, at three feet distance from row to row, and at about ten inches distance in the rows. The second year after the planting out, they will be fit to bud, if they are intended for dwarfs, but if they are intended for standards, they will not be tall enough till the fourth year; for they should be budded or grafted near six feet from the ground. The grafting is usually performed in summer, and the head of the stock is to be cut off in the beginning of the March following, about six inches above the bud; and if the bud has shot well, and there is any fear of its being displaced by winds, it must be gently tied up to the part of the stock left above it. The autumn afterwards these trees will be fit to remove, and be set where they are to remain; or they may be left two years. Many, when they plant these trees in their places, lop off a great part of their heads, but this is an injury that often kills them; and when they escape, they seldom get well over it for four or five years. If the trees are intended for walls, it is advisable to plant dwarfs between the standards, that these may cover the lower part of the wall, while the others spread over the upper part; and when the dwarfs rise to fill the whole walls, the standards should be taken entirely away. When these trees are taken up from the nursery, the dead fibres of the roots must be carefully taken off, and the upper part of the stock which is above the bud, must be cut off close down to the back part of it: the bud must be placed directly from the wall. Cherry-trees thrive best on a dry hazly loam, and in a gravelly soil are very subject to blights, and seldom stand long good. They should be placed at fourteen feet asunder, with a standard tree between each two. In pruning these trees, their shoots should never be shortened, for they mostly produce their fruit from their extreme part. All the fore-right shoots are to be displaced, and the others trained horizontally; and where there is a vacancy in the wall, the branches being shortened, will throw up a shoot or two to fill it.

Of the cherry-laurel there are several sorts cultivated in the gardens about London: they are all propagated by sowing the berries, or by laying down the tender branches, which will take root in one year's time, and may then be transplanted into beds for a year or two, or even placed at once where they are to remain. If they are to be raised by sowing, the berries must be gathered when ripe, which is in January, and kept in dry sand till the beginning of March, when they must be sown in a bed of rich dry earth, well sheltered from the north and east winds. The bed must be levelled, and then furrows of an inch deep made along it, at eight inches distance; into these the berries are to be dropped about two inches asunder, and covered with earth; and if the season prove

very dry they must be watered: they will come up in about two months, and should be suffered to remain in these beds two years. They should then be transplanted into a bed of earth well dug, and set at eighteen inches asunder; this should be done in April, and they should be well watered, and the ground covered with some muck about their roots. They must be trained up straight, by tying them to stakes, and their under shoots pruned off, to make them advance in height. These trees are proper to plant on the warm sides of hills, where they may be sheltered from the north and north-east winds. In open situations the laurel-tree will sometimes indeed lose all its verdure in severe winters, and appear dead, and many trees have on this occasion been dug up and burnt; but this is a rash and very wrong practice; for usually, if they are suffered to remain they shoot freely again, and after another season are found as lively as ever.

**PRURIENCE. PRURIENCY.** *s.* (from *prurio*, Latin.) An itching or a great desire or appetite to any thing (*Swift*).

**PRURIENT.** *a.* (*pruriens*, Latin.) Itching.

**PRURIGINOUS.** *a.* (*prurio*, Latin.) Tending to an itch.

**PRURIGO.** (from *prurio*, to itch.) The prurigo is a genus of disease in the order papulous eruptions of Dr. Willan's cutaneous diseases. As it arises from different causes, or at different periods of life, and exhibits some varieties in its form, he describes it under the titles of prurigo mitis, prurigo formicans, and prurigo senilis. In these the whole surface of the skin is usually affected; but there are likewise many cases of local prurigo, which will be afterwards noticed according to their respective situations.

1. The prurigo mitis originates without any previous indisposition, generally in spring, or the beginning of summer. It is characterized by soft and smooth elevations of the cuticle, somewhat larger than the papulæ of the lichen, from which they also differ by retaining the usual colour of the skin; for they seldom appear red, or much inflamed, except from violent friction. They are not, as in the other case, accompanied with tingling, but with a sense of itching almost incessant. This is, however, felt more particularly on undressing, and often prevents rest for some hours after getting into a bed. When the tops of the papulæ are removed by rubbing or scratching, a clear fluid oozes out from them, and gradually concretes into thin black scabs.

This species of prurigo mostly affects young persons, and its cause may, we think, in general be referred to sordes collected on the skin, producing some degree of irritation, and also preventing the free discharge of the cutaneous exhalations; the bad consequences of which must necessarily be felt at that season of the year when perspiration is most copious. Those who have originally a delicate or irritable skin must likewise in the same circumstances, be the greatest sufferers.

## P R U R I G O.

The eruption extends to the arms, breast, back, and thighs, and often continues during two or three months of the summer, if not relieved by proper treatment. When persons affected with it neglect washing the skin, or are uncleanly in their apparel, the irruption grows more inveterate, and at length changing its form, often terminates in the itch. Pustules arise among the papulæ, some filled with lymph, others with pus. The *acarus scarabiei* begins to breed in the furrows of the cuticle, and the disorder becomes contagious.

2. *P. formicans*. This is a much more obstinate and troublesome disease than the foregoing. It usually affects persons of adult age, commencing at all seasons of the year indifferently; and its duration is from four months to two or three years, with occasional short intermissions. The papulæ are sometimes larger, sometimes more obscure, than in the preceding species; but are, under every form, attended with an incessant, almost intolerable itching. They are diffused over the whole body, except the face, feet, and palms of the hands; they appear, however, in greatest number on those parts which, from the ordinary mode of dress, are subjected to tight ligatures; as about the neck, loins, and thighs.

The itching is complicated with other sensations, which are variously described by patients. They sometimes feel as if small insects were creeping on the skin; sometimes as if stung all over by ants; sometimes as if hot needles were piercing the skin in divers places. On standing before a fire, or undressing, and more particularly on getting into bed, these sensations become most violent, and usually preclude all rest during the greater part of the night. The *prurigo formicans* is by most practitioners deemed contagious, and confounded with the itch. In endeavouring to ascertain the justness of this opinion, Dr. Willan has been led to make the following remarks: 1. The eruption is, for the most part, connected with internal disorder, and arises where no source of infection can be traced. 2. Persons affected may have constant intercourse with several others, and yet never communicate the disease to any of them. 3. Several persons of one family may have the *prurigo formicans* about the same time; but he thinks this should be referred rather to a common predisposition than to contagion, having observed that individuals of a family are often so affected, at certain seasons of the year, even when they reside at a distance from each other.

Although the *prurigo formicans* is never, like the former species, converted into the itch, yet it does occasionally terminate in a pustular disease, not contagious.

3. *P. senilis*. This affection does not differ much in its symptoms and external appearances from the *prurigo formicans*; but has been thought by medical writers to merit a distinct consideration, on account of its peculiar inveteracy. The *prurigo* is perhaps aggravated, or becomes more permanent, in old age, from the dry, condensed state of the skin and cuticle,

which often takes place at that period. Those who are affected with it in a high degree have little more comfort to expect during life, being incessantly tormented with a violent and universal itching. The state of the skin in the *prurigo senilis* is favourable to the production of an insect, the *pediculus humanus*, more especially to the variety of it usually termed body lice.

These insects, it is well known, are bred abundantly among the inhabitants of sordid dwellings, of jails, workhouses, &c. and in such situations prey upon persons of all ages indiscriminately. But in the *prurigo senilis* they arise, notwithstanding every attention to cleanliness or regimen, and multiply so rapidly that the patient endures extreme distress, from their perpetual irritation. The nits or eggs are deposited on the small hairs of the skin, and the pediculi are only found on the skin or on the linen, not under the cuticle, as some authors have represented. In connection with the foregoing series of complaints, Dr. Willan mentions some pruriginous affections which are merely local. He confines his observations to the most troublesome of these, seated in the *podex*, *præputium*, *urethra*, *pubes*, *scrotum*, and *puendum muliebre*. Itching of the nostrils, eyelids, lips, or of the external ear, being generally symptomatic of other diseases, do not require a particular consideration.

1. *P. podicis*. *Ascarides* in the rectum excite a frequent itching and irritation about the sphincter ani, which ceases when the cause is removed by proper medicines. A similar complaint often arises independently of worms, hæmorrhoidal tumors, or other obvious causes, which is mostly found to affect persons engaged in sedentary occupations; and may be referred to a morbid state of secretion in the parts, founded, perhaps, on a diminution of constitutional vigour. The itching is not always accompanied with an appearance of papulæ or tubercles; it is little troublesome during the day-time, but returns every night soon after getting into bed, and precludes rest for several hours. The complaint continues in this form during three or four months, and has then an intermission, till it is produced again by hot weather, fatigue, watching, or some irregularity in diet. The same disease occurs at the decline of life, under a variety of circumstances.

Women, after the cessation of the catamenia, are liable to be affected with this species of *prurigo*, more especially in summer or autumn. The skin between the nates is rough and papulated, sometimes scaly, and a little humour is discharged by violent friction. Along with this complaint, there is often an eruption of itching papulæ on the neck, breast, and back; a swelling and inflammation of one or both ears, and a discharge of matter from behind them, and from the external meatus auditorius. The *prurigo podicis* sometimes occurs as a symptom of the *lues venerea*.

2. The *P. præputii* is owing to an altered state of secretion on the glans penis, and inner surface of the *præputium*. During the heat of

summer there is also, in some persons, unusual discharge of mucus, which becomes acrimonious, and produces a troublesome itching, and often an excoriation of these parts. Washing of them with water, or soap and water, employed from time to time, relieves the complaint, and should indeed be practised as an ordinary point of cleanliness, where no inconvenience is immediately felt. If the fluid be secreted in too large a quantity, that excess may be restrained by washes made with the extract of lead, or by applying the unguentum cerusæ acetatæ.

3. *P. urethralis*. A very troublesome itching sometimes takes place at the extremity of the urethra in females, without any manifest cause. It occurs as well in young women as in those who are of an advanced age. On examination no stricture nor tumour has been found along the course of the urethra. Probably, however, the itching may be occasioned by a morbid state of the neck of the bladder being in some instances connected with pain and difficulty of making water.

An itching at the extremity of the urethra in men is produced by calculi, and by some diseases of the bladder. In cases of stricture an itching is also felt, but near the place where the stricture is situated. Another cause of it is small broken hairs, which are sometimes drawn in from the pubes, between the præputium and glans, and which afterwards becoming fixed in the entrance of the urethra, occasion an itching, or slight stinging, particularly on motion. Mr. J. Pearson, surgeon of the Lock Hospital, has seen five cases of this kind, and gave immediate relief by extracting the small hair from the urethra.

4. *P. pubis*. Itching papulæ often arise on the pubes, and become extremely sore if their tops are removed by scratching. They are occasioned sometimes by neglect of cleanliness, but more commonly by a species of pediculus, which perforates the cuticle, and thus derives its nourishment, remaining fixed in the same situation. These insects are termed by Linnaeus, &c. *pediculi pubis*; they do not, however, affect the pubes only, but often adhere to the eye-brows, eye-lids, and axillæ. They are often found, also, on the breast, abdomen, thighs, and legs, in persons of the sanguine temperament, who have those parts covered with strong hairs. It is remarkable that they seldom or never fix upon the hairy scalp. The great irritation produced by them on the skin solicits constant scratching, by which they are torn from their attachments; and painful tubercles arise at the places where they had adhered. When the pediculi are diffused over the greater part of the surface of the body, the patient's linen often appears as if sprinkled with drops of blood.

5. *P. seroti*. The scrotum is affected with a troublesome and constant itching from ascarides within the rectum, from friction by violent exercise in hot weather, and very usually from the pediculi pubis. Another and more important form of the complaint appears in

old men, sometimes connected with the prurigo podicis, and referable to a morbid state of the skin, or superficial glands of the part. The scrotum, in this case, assumes a brown colour, often also becoming thick, scaly, and wrinkled. The itching extends to the skin covering the penis, more especially along the course of the urethra; and has little respite, either by day or night.

6. The *P. pudendi muliebris* is somewhat analogous to the prurigo seroti in men. It is often a symptomatic complaint in the lichen and lepra; it likewise originates from ascarides irritating the rectum, and in some cases connected with a discharge of the fluor albus.

A similar affection arises in consequence of the change of state in the genital organs at the time of puberty, attended with a series of most distressing sensations. Dr. Willan confines his attention to one case of the disorder, which may be considered as idiopathic, and which usually affects women soon after the cessation of the catamenia. It chiefly occurs in those who are of the phlegmatic temperament, and inclined to corpulency. Its seat is the labia pudendi, and entrance of the vagina. It is often accompanied with an appearance of tension or fulness of those parts, and sometimes with inflamed itching papulæ on the labia and mons veneris. The distress arising from a strong and almost perpetual itching in the above situation may be easily imagined. In order to allay it in some degree, the sufferers have frequent recourse to friction, and to cooling applications: whence they are necessitated to forego the enjoyment of society. An excitement of venereal sensations also takes place from the constant direction of the mind to the parts affected, as well as from the means employed to procure alleviation. The complicated distress thus arising renders existence almost insupportable, and often produces a state of mind bordering on frenzy.

Deep ulcerations of the parts seldom take place in the prurigo pudendi; but the appearance of aphthæ on the labia and nymphæ is by no means unusual. From intercourse with females under these circumstances, men are liable to be affected with aphthous ulcerations on the glans, and inside of the præputium, which prove troublesome for a length of time, and often excite an alarm, being mistaken for chancres.

Women, after the fourth month of their pregnancy, often suffer greatly from the prurigo pudendi, attended with aphthæ. These, in a few cases, have been succeeded by extensive ulcerations which destroyed the nymphæ, and produced a fatal hectic: such instances are, however, extremely rare. The complaint has in general some intervals or remissions; and the aphthæ usually disappear soon after delivery, whether at the full time, or by a miscarriage.

**PRURITUS.** (from *prurio*, to itch.) See PRURIGO.

**PRUSA**, a town of Bithynia, built by king Prusias, from whom it received its name.

## PRU

**PRUSIAS**, a king of Bithynia, who flourished 221 B. C.—2. Another surnamed Venator, who gave a kind reception to Annibal, and by his advice he made war against Eumenes, king of Pergamus, and defeated him. Eumenes complained before the Romans of the hostilities of Prusias; upon which Q. Flaminius was sent from Rome to settle the disputes of the two monarchs. Prusias, upon the arrival of Flaminius, in order to gain his favour, prepared to deliver to him Annibal, who prevented his treachery by a voluntary death. Prusias was obliged to make a restitution of the provinces he had conquered, and when some time after he visited the capital of Italy, he appeared in the habit of a manumitted slave, calling himself the freeman of the Romans. Such abject behaviour rendered him contemptible in the eyes of his subjects, and when he returned home they revolted, and placed his son Nicomedes on the throne. He fled to Nicomedia, where he was assassinated near the altar of Jupiter, about 149 years B. C. Some say that his son was his murderer.

## PRU

**PRUSSIA**, a European kingdom, situated south of the Baltic, and bounded on the other sides by Russia, the grand duchy of Warsaw, the Austrian empire, the kingdoms of Saxony and Westphalia, the states of Hanover and Mecklenburg. Its shape is very irregular, and will be best conceived by inspecting the map. The greatest extent of Prussia is from north-east to south-west, which is about 480 English miles; but its breadth, in a direction perpendicular to the line of greatest extent, seldom exceeds 100 miles; except in a narrow part which stretches from north-west to south-east to the Austrian frontier, in which direction its extent is nearly 400 miles. It reaches from 11° 20' to nearly 23° of east longitude, and from the shores of the Baltic to below the 50th degree of latitude.

A recent German journal gives the following division of this kingdom, with the annexed extent and population of each province.

| Provinces.                                                                                              | Square<br>Ger. Miles. | Population. | Chief Towns. |
|---------------------------------------------------------------------------------------------------------|-----------------------|-------------|--------------|
| 1. Lithuania.....                                                                                       | 315                   | 376,578     | Gumbinnen.   |
| 2. Eastern Prussia .....                                                                                | 386                   | 454,734     | Königsberg.  |
| 3. Western Prussia .....                                                                                | 343                   | 367,067     | Elbing.      |
| 4. Pomerania .....                                                                                      | 442                   | 490,106     | Stettin.     |
| 5. New March .....                                                                                      | 209½                  | 265,714     | Custrin.     |
| 6. { Electoral March; part of the<br>{ county of Magdeburg, on the<br>{ right bank of the river Elbe. } | 416                   | 708,992     | Berlin.      |
| 7. Silesia .....                                                                                        | 668                   | 1,896,359   | Breslau.     |

The surface of the Prussian dominions is rather diversified with hills and plains than rendered abrupt and broken by mountains and valleys. All the provinces, however, but that of Silesia, may be regarded as a level country; while this last rises to considerable eminences towards the south-western limits; where it is separated from Moravia and Bohemia by a branch of the Carpathian chain. Numerous rivers and lakes also add variety and fertility to these territories. The branch of the Carpathian mountains, which partly enters Silesia, is the most elevated region in Prussia, and extends through a space of at least 150 English miles: there are also some detached mountains in the northern parts of the same province; the chief of which, according to Busching, are Spitzberg and Gratzberg; but their precise elevation, as well as that of those in other parts, appears not to have been determined. Many parts of Prussia are covered with forests; especially the eastern parts, and the mountainous regions of Silesia.

The lakes, especially in the eastern districts of the Prussian territories, are numerous. One of the largest of these is the Spelding See, in the south-east part of Prussia proper, which, including its various creeks, extends about 20 miles in every direction. Several small lakes occur in this quarter, as well as more towards

the west, in the central parts of Pomerania, and in the south-west of Brandenburg. Besides these, this kingdom presents several singular inland sheets of water, at the estuaries of some of its principal rivers, which in the German language are called haffs. One of these, denominated Grass Haff, is situated in the north-west part of Pomerania, at the mouth of the Oder. A second extends from Elbing to Königsberg, and is separated from the Baltic, to which it is nearly parallel, by a narrow slip of land, except in a small part where it communicates with that sea. This is styled Frisch Haff; is about 70 English miles in length, and from three to ten in breadth. This gulf is not of sufficient depth to admit ships of large burden; and the bank which separates it from the Baltic is said to have been thrown up by the violence of tempests, about the end of the twelfth century. Another of these gulfs commences a few miles north of the last, stretches northward, and enters the sea opposite Memel. This is called Curisch Haff; is broadest at its southern extremity, but very narrow towards the opposite end. Its length is nearly 60 English miles, and greatest breadth about half that number; while the space between it and the sea is also very narrow. It is subject to frequent storms, which in conjunction with its numerous shoals render the navigation dangerous.

Though Prussia is watered by several large rivers, they originate in foreign sources, and are received into the dominions with the accumulated waters of more than half their course. The Oder and the Pregel, however, may be regarded as Prussian rivers. The former springs from the mountains in the northern part of Moravia, soon after enters the southern parts of Silesia, flows through the middle of that province, forms a part of the boundary between Prussia and the kingdom of Saxony, crosses Brandenburg and Pomerania, and falls into the Grass Haff, after having passed through an extent of nearly 400 miles. The Pregel originates in some lakes near the south-east extremity of the dominions, and passes by Königsberg into the northern end of the Frisch Haff. The Elbe constitutes the separation between the Prussian territories and the kingdom of Westphalia. The Spree rises in the kingdom of Saxony, flows through Berlin, and enters the Elbe. The Vistula and the Memel likewise complete their courses by flowing through this kingdom; the former into the Frisch Haff, and the latter into that of Curisch.

The Prussian government is founded on a military basis; and as there is no senate, it must be regarded as an absolute monarchy. The army, which has recently been much reduced in number, consists of about 150,000 men; and as local circumstances call the whole attention of the Prussian government to the formation, discipline, and maintenance of the land forces, neither a navy nor colonies are classed among its possessions. The revenue of the crown is estimated at a little more than four millions sterling; and as there is no national debt, and the chief expense is incurred by the support of the army, this small revenue has been found equal to the expenses of the state.

Prussia produces a great deal of flax, hemp, and corn; and yellow amber is found along the sea-coast. The domestic animals are numerous; and, beside the common game, there are elks, wild asses, and uris, in the forests. The uris are of a monstrous size, and have some resemblance to beavers: their hides are extremely thick and strong, and are sold to foreigners at a great price. Königsberg is the capital. For more on the subject of Prussia, the reader may consult Mr. Myers's valuable *System of Geography*, just published; from which the substance of this article has been taken.

**PRUSSIAN BLUE.** See **PRUSSIC ACID.**

**PRUSSIATS.** Salts formed by the union of prussic acid with various bases, as sulphats are salts formed with sulphuric acid and various bases; and nitrats salts formed with nitric acid and various bases. For the means of producing prussic acid the reader must advert to the ensuing article.

The salts thus produced are as follows.

1. *Prussiat of lime*, formed by dissolving lime in prussic acid, filtering the solution, and separating the uncombined lime. It is decomposed by all the other acids, and by alkalies.

2. *Prussiat of magnesia*.—This salt may be formed by putting pure magnesia into prussic acid. In a few days the earth is dissolved, and the compound formed. The magnesia is precipitated by the alkalies and lime, and by exposure to the air.

3. *Prussiats of iron*.—As the prussiats of iron enter as ingredients into the triple salts formed by the prussic acid, it will be necessary to give some account of them before entering upon the consideration of these triple salts.

It has been demonstrated by chemists, that there are no fewer than four prussiats of iron: namely,

1. White prussiat,
2. Blue prussiat,
3. Yellow prussiat,
4. Green prussiat.

The white prussiat discovered by Mr. Proust is composed of prussic acid and protoxyd of iron. It becomes gradually blue when exposed to the atmosphere, because the oxyd absorbs oxygen, and is converted into peroxyd.

Blue prussiat, or Prussian blue, is composed of prussic acid and peroxyd of iron. It is a deep-blue powder, insoluble in water, and scarcely soluble in acids. It is composed, according to the most accurate experiments hitherto made, of equal parts of oxyd of iron and prussic acid. It is not affected by exposure to the air. Heat decomposes it by destroying the acid, and the oxyd of iron remains behind. The Prussian blue of commerce, besides other impurities, contains mixed with it a great quantity of alumina.

Yellow prussiat is composed of prussic acid combined with an excess of peroxyd of iron: it is therefore a sub-prussiat of iron. This prussiat is soluble in acids. It may be obtained by digesting the alkalies or alkaline earths with Prussian blue. Part of the acid is carried off by these bodies, and the yellow prussiat remains in the state of a powder.

Green prussiat, first discovered by Mr. Berthollet, is composed of oxyprussic acid, and peroxyd of iron. It is therefore in fact an oxyprussiat.

4. *Prussiat of barytes and iron*.—For the first accurate description of this salt, we are indebted to the ingenious Mr. William Henry. It may be formed by adding Prussian blue to hot barytes water till it ceases to be discoloured. The solution, when filtered and gently evaporated, yields crystals of prussiat of barytes and iron.

These crystals have the figure of rhomboidal prisms; they have a yellow colour, and are soluble in 1920 parts of cold water, and in about 100 parts of boiling water. In a red heat they are decomposed, the acid being destroyed. They are soluble in nitric and muriatic acids: sulphuric acid occasions a precipitate of sulphat of barytes.

5. *Prussiat of lime and iron*.—This salt was perhaps first mentioned by Mr. Hagen; but we are indebted to Morveau for the first ac-

# PRUSSIATS.

curate account of its properties and preparation.

Upon two parts of Prussian blue of commerce, previously well washed with a sufficient quantity of boiling water to separate all the foreign salts, about 56 parts of lime-water are to be poured, and the mixture must be boiled for a short time till the lime is saturated with the prussic acid, which is known by its no longer altering paper stained with turmeric: it is then to be filtered.

This liquid, which contains the triple prussiat of lime in solution, has a greenish-yellow colour: its specific gravity is 1.005; and it has an unpleasant bitterish taste. When evaporated to dryness, it yields small crystalline grains, soluble without alteration in water. It is insoluble in alcohol.

This triple prussiat may be used with advantage as a test to ascertain the presence of metals held in solution. The only impurity which it contains is a little sulphat of lime.

6. *Prussiat of potass and iron.*—This salt, known also by the names of Prussian alkali, phlogisticated alkali, Prussian test, triple prussiat of potass, &c. has been chosen by chemists as the best combination of prussic acid for detecting the presence of metals, and more especially for detecting the existence of iron. To chemists and mineralogists, it is one of the most important instruments ever invented; as, when properly prepared, it is capable of indicating whether any metallic substance (plantinum excepted) is present in any solution whatever, and even of pointing out the particular metal, and of ascertaining its quantity. This it does by precipitating the metals from their solution in consequence of the insoluble compound which it forms with them; and the colour of the precipitate indicates the particular metal, while its quantity enables us to judge of the proportion of metallic oxyd contained in any solution.

In order to be certain of the accuracy of these results, it is necessary to have a Prussian alkali perfectly pure, and to be certain beforehand of the quantity, or rather of the proportions, of its ingredients. To obtain a test of this kind has been the object of chemists ever since the discoveries of Macquer pointed out its importance. It is to the use of impure tests that a great part of the contradictory results of mineralogical analysis by different chemists is to be ascribed.

The great object of chemists at first was to obtain this prussiat entirely free from iron; but their attempts uniformly failed, because the oxyd of iron is one of its necessary component parts. This was first properly pointed out by Morveau.

There are two ways in which this test may be rendered impure, besides the introduction of foreign ingredients, which it is needless to mention, because it is obvious that it must be guarded against. 1. There may be a superabundance of alkali present, or, which is the same thing, there may be mixed with the

Prussian test a quantity of pure alkali: or, 2. There may be contained in it a quantity of yellow prussiat of iron, for which prussiat of potass has also a considerable affinity.

If the Prussian test contains a superabundance of alkali, two inconveniences follow. This superabundant quantity will precipitate those earthy salts which are liable to contain an excess of acid, and which are only soluble by that excess: hence alumina and barytes will be precipitated. It is to the use of impure tests of this kind that we owe the opinion, that barytes and alumina are precipitated by the Prussian alkali, and the consequent theories of the metallic nature of these earths. This mistake was first corrected by Meyer of Steint.

Another inconvenience arising from the superabundance of alkali in the Prussian test is, that it gradually decomposes the blue prussiat which the test contains, and converts it into yellow prussiat. In what manner it does this will be understood, after what has been said, without any explanation.

On the other hand, when the Prussian alkali contains a quantity of yellow prussiat of iron, as great inconveniences follow. This yellow prussiat has an affinity for prussic acid, which, though inferior to that of the potass, is still considerable; and, on the other hand, the potass has a stronger affinity for every other acid than for the prussic. When, therefore, the test is exposed to the air, the carbonic acid which the atmosphere always contains, assisted by the affinity between the yellow prussiat and the prussic acid, decomposes the prussiat of potass in the test, and the yellow prussiat is precipitated in the form of Prussian blue; and every other acid produces the same effect. A test of this kind would indicate the presence of iron in every mixture which contains an acid (for a precipitation of Prussian blue would appear), and could not therefore be employed with any confidence.

To describe the various methods proposed by chemists for preparing this salt would be unnecessary, as the greater number do not answer the purpose intended. The method practised by Klaproth, first made known to chemists by Westrum, and afterwards described in our language by Kirwan, is considered as one of the best. It is as follows:

Prepare pure potass, by gradually projecting into a large crucible, heated to whiteness, a mixture of equal parts of purified nitre and crystals of tartar; when the whole is injected let it be kept at a white heat for half an hour, to burn off the coal. Detach the alkali thus obtained from the crucible, reduce it to powder, spread it on a muffle, and expose it to a white heat for half an hour. Dissolve it in six times its weight of water, and filter the solution while warm. Pour this solution into a glass receiver, placed in a sand-furnace heated to 170° or 180°; and then gradually add the best Prussian blue in powder, injecting new portions according as the former become

# PRUSSIATS.

grey, and supplying water as fast as it evaporates; continue until the added portions are no longer discoloured, then increase the heat to  $212^{\circ}$ , and continue it for half an hour. Filter the ley thus obtained, and saturate it with sulphuric acid moderately diluted; a precipitate will appear: when this ceases, filter off the whole, and wash the precipitate. Evaporate the filtered liquor to about one quarter, and set it by to crystallize: after a few days, yellowish crystals of a cubic or quadrangular form will be found, mixed with some sulphat of potass and oxyd of iron; pick out the yellowish crystals, lay them on blotting-paper, and re-dissolve them in four times their weight of cold water, to exclude the sulphat of potass.

Assay a few drops of this solution with barytes water, to see whether it contains any sulphuric acid, and add some barytes water to the remainder if necessary: filter off the solution from the sulphat of barytes, which will have precipitated, and set it by to crystallize for a few days; that the barytes, if any should remain, may be precipitated. If the crystals now obtained are of a pale yellow colour, and discover no blueish streaks when sprinkled over with muriatic acid, they are fit for use; but if they still discover blueish or green streaks, the solutions and crystallizations must be repeated.

These crystals must be kept in a well-stopped bottle, which, to preserve them from the air, should be filled with alcohol, as they are insoluble in it.

Before they are used, the quantity of iron they contain should be ascertained, by heating 100 grains to redness for half an hour in an open crucible: the prussic acid will be consumed, and the iron will remain in the state of a reddish-brown magnetic oxyd, which should be weighed and noted. This oxyd is half the weight of the Prussian blue afforded by the Prussian alkali: its weight must therefore be subtracted from that of metallic precipitates formed by this test. Hence the weight of the crystals, in a given quantity of the solution, should be noted, that the quantity employed in precipitation may be known. Care must be taken to continue the calcination till the oxyd of iron becomes brown; for while it is black, it weighs considerably more than it should.

Another good method of preparing this salt has been lately given by Mr. Henry; but it is rather too expensive for general use. It consists in first forming a triple prussiat of barytes, and adding it in crystals to a solution of carbonat of potass till the solution no longer restores the colour of reddened litmus paper. After digesting the mixture for half an hour, filter the liquid, and evaporate it gently. The triple prussiat of potass crystallizes.

7. Besides this triple salt, which is often, for the sake of abbreviation, called prussiat of potass, though iron is a constituent part, a simple prussiat of iron may also be obtained. It cannot however be made by the direct combination of the prussic acid and iron, but is

always the result of the decomposition of the solution of iron in another acid. When the pure prussic acid is added to any solution of this metal, the prussiat of iron thus formed is at first green, and is soluble in acids; hence much of it, and often the whole, remains in the solution, and no precipitate occurs. But on exposure to the rays of light, or to sulphuric acid, or if metallic iron be added to the solution, the colour becomes blue, and the prussiat, which is now no longer soluble in the acids, falls down. Whence it would appear that pure blue prussiat of iron (which may be distinguished from Prussian blue by containing nothing but prussic acid and oxyd of iron) holds the metal in a less oxygenated state than in the green solution.

8. *Prussiat of mercury.*—The prussic acid exercises so strong an action on the oxyd of mercury, that even corrosive muriat is decomposed by Prussian blue, as indeed are all the oxyds of this metal in an equal degree. The prussiat of mercury duly evaporated crystallizes in tetrahedral prisms. It is the only simple combination of this acid and a metallic oxyd which will crystallize.

9. *Prussiat of silver.*—The pure prussic acid when added to nitrated silver precipitates a white prussiat of silver. When this metal is previously separated from its solution by carbonat of soda, this acid unites with it and forms white prussiat as before, and expels the carbonic acid which it contains.

10. *Prussiat of copper.*—Digested with the carbonated oxyd of copper, the pure prussic acid effervesces and turns it of a faint lemon colour, but it does not alter the solutions of this metal. If the pure prussiat of lime be added to the sulphat of copper, it first precipitates a lemon-coloured prussiat of copper, which more of the liquor redissolves, and this solution is soluble in ammonia without turning it blue. If more of the sulphat of copper be added, the precipitate in like manner will disappear.

The other metallic prussiats are similarly formed, but of little importance.

11. *Prussiat of strontian.*—This salt is prepared like that of barytes by digesting Prussian blue with the pure earth: but this prussiat does not readily crystallize, and appears to be extremely insoluble in water.

**PRUSSIC ACID**, an acid of a very singular nature, and of very essential use in a variety of chemical operations, as also regarded as a pigment in manufactures. It was discovered about a century ago by Diesbach at Berlin; and a method of preparing it was published by Woodward in the Philosophical Transactions for 1724, which he said he had got from one of his friends in Germany. This method was as follows: Detonate together four ounces of nitre and as much tartar, in order to procure an extemporaneous alkali; then add four ounces of dried bullock's blood; mix the ingredients well together, and put them into a crucible covered with a lid, in which there is a small hole; calcine with a moderate fire till the blood emits no more smoke or flame capa-

## P R U S S I C A C I D.

ble of blackening any white body exposed to it: increase the fire towards the end, so that the whole matter contained in the crucible shall be moderately but sensibly red. In this state throw it into two pints of water, and boil it for half an hour. Decant off this water, and continue to pour on more till it comes off insipid. Add all these liquids together, and boil them down to two pints. Dissolve two ounces of sulphat of iron and eight ounces of alum in two pints of boiling water; mix this with the former liquor while both are hot. An effervescence takes place, and a powder is precipitated, of a green colour mixed with blue. Separate this precipitate by filtration, and pour muriatic acid upon it till it becomes of a beautiful blue; then wash it with water and dry it.

Different explanations were given of the nature of this precipitate by different chemists. All of them acknowledged that it contained iron; but to account for the colour was the difficult point. Brown, and Geoffroy, and Neuman, discovered in succession, that a great many other animal substances besides blood communicated to alkalies the property of forming Prussian blue; but the theories by which they attempted to account for its formation were altogether nugatory. At last a very important step was made in the investigation of this compound by Macquer, who published a dissertation on it in the year 1752.

This celebrated chemist ascertained the following facts: 1. When an alkali is added to a solution of iron in any acid, the iron is precipitated of a yellow colour, and soluble in acids; but if iron is precipitated from an acid by an alkali prepared by calcination with blood (which has been called a Prussian alkali), it is of a green colour. 2. Acids dissolve only a part of this precipitate, and leave behind an insoluble powder, which is of an intense blue colour. The green precipitate, therefore, is composed of two different substances, one of which is Prussian blue. 3. The other is the brown or yellow oxyd of iron; and the green colour is owing to the mixture of the blue and yellow substances. 4. When heat is applied to this Prussian blue, its blue colour is destroyed, and it becomes exactly similar to common oxyd of iron. It is composed, therefore, of iron and some other substance, which heat has the property of driving off. 5. If it is boiled with a pure alkali, it loses its blue colour also, and at the same time the alkali acquires the property of precipitating of a blue colour solutions of iron in acids, or it has become precisely the same with the Prussian alkali. 6. Prussian blue, therefore, is composed of iron and something which a pure alkali can separate from it, something which has a greater affinity for alkali than for iron. 7. By boiling a quantity of alkali with Prussian blue, it may be completely saturated with this something, which may be called colouring matter. 8. No acid can separate this colouring matter from iron after it is once united with it. 9. When iron dissolved in an acid is mixed with an alkali

saturated with the colouring matter, a double decomposition takes place, the acid unites with the alkali, and the colouring matter with the iron, and forms Prussian blue. 10. The reason that, in the common method of preparing Prussian blue, a quantity of yellow oxyd is precipitated, is, that there is not a sufficient quantity of colouring matter (for the alkali is never saturated with it) to saturate all the iron displaced by the alkali; a part of it, therefore, is mixed with Prussian blue. Muriatic acid dissolves this oxyd, carries it off, and leaves the blue in a state of purity.

Such were the conclusions which Macquer drew from his experiments; experiments which not only discovered the composition of Prussian blue, but threw a ray of light on the nature of affinities, which has contributed much towards the advancement of that important branch of chemistry.

The nature of the colouring matter, however, was still unknown. At length, in 1772, Morveau announced his suspicion that the colouring matter was probably an acid.

Such was the knowledge of chemists respecting the nature of this colouring matter, when Scheele all at once removed the veil, and explained its properties and composition. He observed that the Prussian alkali, after being exposed for some time to the air, lost the property of forming Prussian blue; the colouring matter must therefore have left it. He put a small quantity of it into a large glass globe, corked it up, and kept it some time; but no change was produced either in the air or the Prussian alkali. Something must therefore displace the colouring matter when the alkali is exposed to the open air, which is not present in a glass vessel. Was it carbonic acid gas? To ascertain this, he put a quantity of Prussian alkali into a glass globe filled with that gas, and in 24 hours the alkali was incapable of producing Prussian blue. It is therefore carbonic acid gas which displaces the colouring matter. He repeated this experiment with this difference, that he hung in the globe a bit of paper which had been previously dipped into a solution of sulphat of iron, and on which he had let fall two drops of an alkaline lixivium in order to precipitate the iron. This paper was taken out in two hours, and became covered with a fine blue on adding a little muriatic acid. Carbonic acid, then, has the property of separating the colouring matter from alkali without decomposing it.

He found also that other acids produce the same effect. Hence he concluded, that the colouring matter might be obtained in a separate state. Accordingly he made a great many attempts to procure it in that state, and at last discovered the following method, which succeeds perfectly.

Mix together ten parts of Prussian blue in powder, five parts of the red oxyd of mercury, and thirty parts of water, and boil the mixture for some minutes in a glass vessel. The blue colour disappears, and the mixture becomes

## P R U S S I C   A C I D .

yellowish-green. Pour it upon a filter; and after all the liquid part has passed, pour ten parts of hot water through the filter to wash the residuum completely. The oxyd of mercury decomposes Prussian blue, separates its colouring matter, and forms with it a salt soluble in water. The liquid, therefore, which has passed through the filter contains the colouring matter combined with mercury. The other component parts of the Prussian blue, being insoluble, do not pass through the filter. Pour this mercurial liquid upon  $2\frac{1}{2}$  parts of clean iron filings, quite free from rust. Add at the same time one part of concentrated sulphuric acid, and shake the mixture. The iron filings are dissolved, and the mercury formerly held in solution is precipitated in the metallic state. The cause of this sudden change is obvious: the iron deoxygenizes the mercury, and is at the same instant dissolved by the sulphuric acid, which has a stronger affinity for it than the colouring matter has. There remain in solution, therefore, only sulphat of iron and the colouring matter.

Now the colouring matter being volatile, which the sulphat of iron is not, it was easy to obtain it apart by distillation. Accordingly he distilled the mixture in a gentle heat: the colouring matter came over by the time that one-fourth of the liquor had passed into the receiver. It was mixed, however, with a small quantity of sulphuric acid; from which he separated it by distilling a second time over a quantity of carbonat of lime. The sulphuric acid combines with the lime, and remains behind, which the colouring matter cannot do, because carbonic acid has a stronger affinity for lime than it has. Thus he obtained the colouring matter in a state of purity.

It remained now to discover its component parts. He formed a very pure Prussian blue, which he distilled, and increased the fire till the vessel became red. The small quantity of water which he had put into the receiver contained a portion of the blue colouring matter and of ammonia; and the air of the receiver consisted of azote, carbonic acid gas, and the colouring matter. He concluded, from this and other experiments, that the colouring matter is a compound of ammonia and oil. But when he attempted to verify this theory by combining together ammonia and oil, he could not succeed in forming colouring matter. This obliged him to change his opinion; and at last he concluded that the colouring matter is a compound of ammonia and charcoal. He mixed together equal quantities of pounded charcoal and potass, put the mixture into a crucible, and kept it red-hot for a quarter of an hour: he then added a quantity of sal ammoniac in small pieces, which he pushed to the bottom of the melted mixture, kept it in the fire for two minutes till it had ceased to give out vapours of ammonia, and then threw it into a quantity of water. The solution possessed all the properties of the Prussian alkali. Thus Mr. Scheele succeeded in forming the colouring matter.

This colouring matter was called prussic acid by Morveau, in the first volume of the chemical part of the *Encyclopedie Methodique*; an appellation which is now generally received.

These admirable experiments of Scheele were repeated and carried still farther, by Berthollet, in 1787, who applied to the explanation of the composition of the colouring matter the light which had resulted from his previous experiments on the component parts of ammonia. This illustrious chemist, scarcely inferior to Scheele in ingenuity and address, ascertained, in the first place, that the prussic alkali is a triple salt, composed of prussic acid, the alkali, and oxyd of iron; that it may be obtained in octahedral crystals; and that when mixed with sulphuric acid, and exposed to the light, it lets fall a precipitate of Prussian blue. His next object was, to ascertain the component parts of prussic acid. When oxymuriatic acid is poured into prussic acid obtained by Scheele's process, it loses its oxygen, and is converted into common muriatic acid. At the same time the prussic acid becomes more odorous and more volatile, less capable of combining with alkalies, and precipitates iron from its solutions, not blue, but green. Thus prussic acid, by combining with oxygen, acquires new properties, and is converted into a new substance, which may be called oxyprussic acid. If more oxymuriatic acid gas is made to pass into prussic acid, and it is exposed to the light, the prussic acid separates from the water with which it was combined, and precipitates to the bottom in the form of an aromatic oil; which heat converts into a vapour insoluble in water, and incapable of combining with iron. When the green precipitate, composed of oxyprussic acid and iron, is mixed with a pure fixed alkali, the oxyprussic acid is decomposed, and converted into carbonat of ammonia.

From these experiments, Berthollet concluded, that prussic acid does not contain ammonia ready-formed; but that it is a triple compound of carbon, hydrogen, and azote, in proportions which he was not able to ascertain. This conclusion has been still farther verified by Mr. Clouet, who found that when ammoniacal gas is made to pass through a red-hot porcelain tube containing charcoal, a quantity of prussic acid is formed. This experiment does not succeed unless a pretty strong heat is applied to the tube.

Fourcroy and several other chemists believe, that the prussic acid contains also a portion of oxygen in its composition, resting chiefly upon the following experiments of Vauquelin:

Exper. I. Put into a retort 100 parts of the muriat of ammonia, 50 parts of lime, and 25 parts of charcoal in fine powder; adapt to the retort a receiver containing a slight solution of the sulphat of iron, and immerse into it the beak of the retort; then apply a brisk heat, and continue the action of the fire until nothing more is disengaged.

Exper. II. Put into a retort 100 parts of the muriat of ammonia, 50 parts of semivitre-

## PRUSSIC ACID.

ous oxyd of lead, and 25 parts of charcoal: adapt a receiver containing a solution of sulphat of iron, and proceed as before. Stir well the liquors contained in the receivers, and expose them to the air for several days, in order that the combination between the oxyd of iron and the prussic acid may be perfect, and that the prussiat of iron may absorb as much oxygen as is necessary for its passing to the state of blue prussiat, and for its being proof against acids: then pour into these liquors equal quantities of sulphuric acid well diluted with water, and you will have Prussian blue, the quantities of which will be as one to six; that is to say, the Prussian blue of the experiment in which Vauquelin employed oxyd of lead was six times more abundant than that of the experiment in which he employed only lime to disengage the ammonia.

Having thus traced the gradual progress of philosophers in ascertaining the nature of the prussic acid, it only remains to give an account of its properties, which were first examined by the indefatigable Scheele.

Prussic acid obtained by Scheele's process is a colourless liquid like water. It has a strong odour, resembling that of the flowers of the peach, or of bitter almonds. Its taste is sweetish, acrid, and hot, and apt to excite cough. It does not alter the colour of vegetable blues.

It is exceedingly volatile, and evidently capable of assuming the gaseous form; though it has never been obtained apart, nor examined in that state. At a high temperature (when united to a base), it is decomposed and converted into ammonia, carbonic acid, and carbureted hydrogen gas.

It unites difficultly with alkalies and earths, and is separated from them much more easily than from metallic oxyds. Mere exposure to the light of the sun, or to a heat of  $110^{\circ}$ , is sufficient for that purpose. These combinations are decomposed also by all the acids.

It has no action on metals; but it unites with their oxyds, and forms with them salts, which are almost all insoluble, if we except prussiats of mercury and manganese. These compounds are not decomposed by acids. Yet the prussic acid is not capable of taking the metallic oxyds from the other acids.

Prussic acid has a great tendency to enter into triple compounds, combining at once with an alkali and a metallic oxyd; and these compounds are much more permanent and difficult to decompose than its single combinations.

The affinities of this acid, as far as they have been ascertained, are as follows:

Barytes,  
Strontian,  
Potass,  
Soda,  
Lime,  
Magnesia,  
Ammonia.

It does not seem capable of combining with alumina.

This acid is of great importance to the che-

mist, in consequence of the property which it has of forming insoluble compounds with metallic oxyds, and almost with metallic oxyds alone. This puts it in our power to ascertain the presence of a metallic body held in solution. When the prussic acid is dropt in, a precipitate appears if a metal is present. The colour of this precipitate indicates the metal, and the quantity of it enables us to ascertain the quantity of metal contained in the solution. It is used especially to indicate the presence of iron, which it does by the blue colour that the solution assumes: and to free solutions from iron, which it does by precipitating the iron in the form of Prussian blue.

It is evident, however, that the pure prussic acid cannot be employed for these purposes, because it is incapable of taking metallic oxyds from other acids. It is always employed combined with an alkaline or earthy basis. In that state it decomposes all metallic salts by a compound affinity. The base most commonly employed is potass or lime; and indeed it is most usually employed in the state of a triple salt, composed of prussic acid, potass, and oxyd of iron, which is preferred because it is not apt to be decomposed by the action of the atmosphere.

Of all the metallic solutions tried by Scheele, pure prussic acid occasioned only a precipitate in three, namely,

1. Nitrat of silver precipitated white.
2. Nitrat of mercury precipitated black.
3. Carbonat of iron precipitated green becoming blue.

It has no action on the oxyds of

|           |                |
|-----------|----------------|
| Platinum, | Antimony,      |
| Iron,     | Manganese,     |
| Tin,      | Arsenic acid,  |
| Lead,     | Molybdic acid. |
| Bismuth,  |                |

Gold precipitated by the alkaline carbonats is rendered white by this acid.

It disengages carbonic acid from the oxyd of silver precipitated by the same alkalies; but the oxyd remains white.

It dissolves red oxyd of mercury, and forms with it a salt which may be obtained in crystals.

Oxyd of copper precipitated by carbonat of potass, effervesces in it, and acquires a slight orange-yellow colour.

Oxyd of iron precipitated from the sulphat of iron, by carbonat of potass, effervesces in it, and becomes blue.

Oxyd of cobalt precipitated by the same alkali, gives in it some marks of effervescence, and becomes a yellowish brown.

The compounds which prussic acid makes with zirconia and yttria, seem also to be insoluble; for these earths are precipitated from their solutions by prussiat of potass; a circumstance in which they differ from all the other earths and alkalies, and which indicates a coincidence between them and the metallic oxyd.

One of the most obvious characters of this acid is its peach-blossom smell, and by this as

well as by the blue precipitate which it forms with solutions of iron, it is often detected during a variety of decomposing operations of animal substances whether spontaneous or artificial. Thus Vauquelin found it produced by the action of nitric acid on serum, and Fourcroy and others have discovered it as an occasional product (though rare) of animal putrefaction. It is also contained in small quantities in the vegetable kingdom; and here the smell is sometimes an indication, as in bitter-almonds, peach-flowers, the leaves of the lauro-cerasus, &c. As these contain a poisonous principle, it has been conjectured, with some probability, that it may reside in the prussic acid, which is itself highly deleterious.

M. Shrader detected this acid in these vegetable substances by adding lime to the concentrated effusion or distilled water, and afterwards applying a solution of iron and acid. Vauquelin also obtained a notable quantity of the prussic acid in the distilled waters from the kernels of apricots and of bitter almonds. These waters were mixed with a solution of iron, then precipitated entirely by ammonia, and after stirring the mixture, and letting it repose for some hours, sulphuric acid was added, which dissolved the excess of oxyd of iron, and left an insoluble blue-green precipitate, which retained its colour for some days, but immediately became blue in the heat of boiling water.

PRUTH, a river of Poland, which rises in Red Russia, in the mountain of Crapach, crosses part of the palatinate of Lemburg, runs through all Moldavia, and falls into the Danube.

To PRY. *v. n.* (of unknown derivation.) To peep narrowly; to inspect officiously, curiously, or impertinently (*Shakspeare*).

PRYTANES, in Grecian antiquity, were the presidents of the senate, whose authority consisted chiefly in assembling the senate; which, for the most part, was done once every day. The senate consisted of 500, 50 senators being elected out of each tribe: after which, lots were cast, to determine in what order the senators of each tribe should preside; which they did by turns, and during their presidency were called prytanes. However, all the 50 prytanes of the tribes did not govern at once, but one at a time, viz. for seven days; and after 35 days, another tribe came into play, and presided for other five weeks, and so of the rest.

PSALM, a divine song or hymn; but chiefly appropriated to the 150 psalms of David, a canonical book of the Old Testament. Most of the psalms have a particular title, signifying either the name of the author, the person who was to set it to music or sing it, the instrument that was to be used, or the subject and occasion of it. Some have imagined that David was the sole author of the Book of Psalms; but the titles of many of them prove the contrary, as psalm xc, which appears to have been written by Moses. Many of the psalms are

inscribed with the names Korah, Jeduthun, &c. from the persons who were to sing them.

PSALMANAZAR (George), an extraordinary character, whose real name and birth-place are unknown, though he is supposed to be a native of France. Educated among the jesuits, he began early to impose upon the world, first as a pilgrim, and afterwards as a native of Formosa. He travelled from Germany to Liege, pretending to be a Japanese converted to christianity; but afterwards he professed himself to be a heathen, and by the zeal of the chaplain of Lauder's regiment, at Sluys, he was converted to christianity, and baptized. This procured him an easy introduction to Compton, bishop of London, who took him into his house. He was prevailed on to translate the church catechism into the Formosan language, and he also composed a grammar of that language; and though some suspected the imposition, he was generally considered by the learned as a man of superior abilities. He afterwards published his history of Formosa, which quickly passed through two editions; and to obtain greater confidence, he accustomed himself to feed on raw flesh, roots, and herbs. Some absurdities, however, were discovered in his history, and at last, after living long on the credulity of the public, he confessed himself an impostor. Thus abandoned by his former patrons, he yet found sufficient means to subsist by his pen; and undertook a share in the universal history. He died 1763, ashamed of the vile imposition he had practised.

PSALMIST, in the church of Rome, one of the lesser ecclesiastical orders; the same with what among us is called clerk, precentor, or singer.

PSALMODY, the art or act of singing psalms. See PSALM. Psalmody was always esteemed a considerable part of devotion, and usually performed in the standing posture: and as to the manner of pronunciation, the plain song was sometimes used, being a gentle inflection of the voice, not much different from reading, like the chaunt in cathedrals; at other times more artificial compositions were used, like our anthems.

As to the persons concerned in singing, sometimes a single person sung alone; sometimes the whole assembly joined together, which was the most ancient and general practice. At other times, the psalms were sung alternately, the congregation dividing themselves into two parts, and singing verses about, in their turns. There was also a fourth way of singing, pretty common in the fourth century, which was, when a single person began the verse, and the people joined with him in the close: this was often used for variety, in the same service with alternate psalmody.

The use of musical instruments, in the singing of psalms, seems to be as ancient as psalmody itself; the first psalm we read of being sung to the timbrel, viz. that of Moses and Miriam, after the deliverance of the Israelites

from Egypt: and afterwards, musical instruments were in constant use in the temple of Jerusalem.

**PSALTER**, the same with the book of psalms. See the article **PSALM**. Among the religious in the Popish countries, the term psalter is also given to a large chaplet or rosary, consisting of 150 beads, according to the number of psalms in the psalter.

**PSALTERIUM** (*psalterium*, a harp; because it is marked with lines that give it the appearance of a harp.) *Lyra*. In anatomy, the medullary body that unites the posterior crura of the for-nix of the brain.

**PSALTERY**, a musical instrument, much in use among the ancient Hebrews, who called it nebel. We know little or nothing of the precise form of the ancient psalter. That now in use is a flat instrument, in form of a trapezium or triangle truncated at top: it is strung with 13 wire-chords, set to unison or octave, and mounted on two bridges, on the two sides: it is struck with a plectrum, or little iron rod, and sometimes with a crooked stick. Its chest or body resembles that of a spinet.

**PSAMMETICUS**, or **PSAMMITICHUS**, a renowned conqueror, who, subduing 11 other petty kings of Egypt, became the founder of the kingdom of Egypt, about 670 B. C. He is memorable likewise for taking the city of Azot, after a siege of 29 years; and for discovering the sources of the river Nile.

**PSAPHO**, a Libyan who taught a number of birds which he kept to say, "Psapho is a god," and afterwards gave them their liberty. The birds did not forget the words which they had been taught, and the Africans paid divine honours to Psapho.

**PSATHURA**, in botany, a genus of the class hexandria, order monogynia. Calyx superior, six-toothed; corol campanulate, six-cleft, bearded within; stigma lamellate; drupe dry, striate, six-celled, with a seed in each cell. One species; a shrub of the isle of Bourbon, with knotty fragile branches; terminal panicle.

**PSATYRIANS**, a sect of Arians, who, in the council of Antioch, held in the year 360, maintained, that the Son was not like the Father as to will; that he was taken from nothing, or made of nothing; and that, in God, generation was not to be distinguished from creation.

**PSSELLISMUS**. (*ψελλισμος*; from *ψελλίζω*, hesitation of speech.) Defect of speech. A genus of disease in the class locales and order dyscenesiæ of Cullen.

**PSEUDO**, from *ψευδος*, a Greek term used in the composition of many words, to denote false or spurious: as the pseudo-acacia, or bastard-acacia; pseudo-fumaria, or bastard-fumitory; pseudo-ruta, or bastard-rue, &c. We also say, a pseudo-apostle, or false apostle; a pseudo-prophet, or false prophet, &c.

**PSEUDO-ACACIA**, in botany. See **ROBINIA**.

**PSEUDO-ACORUS**, in botany. See **IRIS**.  
**PSEUDO-ASPHODELUS**, in botany. See **ANTHERICUM**.

**PSEUDO-CAPSICUM**, in botany. See **SOLANUM**.

**PSEUDO-DIGITALIS**, in botany. See **DRA-COCEPHALUM**.

**PSEUDOBLEPSIS**. (*ψευδοβλεψις*; from *ψευδος*, false, and *βλεψις*, sight.) Imaginary vision of objects. A genus of disease in the class locales and order dyæsthesiæ of Cullen; characterized by depraved sight, creating objects, or representing them different from what they are. Species: 1. Pseudoblepsis imaginaria, in which objects are perceived that are not present. 2. Pseudoblepsis mutans, in which objects that are present appear somewhat changed.

**PSEUDOGRAPHY**. *s.* False writing.  
**PSEUDOLOGY**. *s.* Falsehood of speech.

**PSEUDONYMUS**, among critics, an author who publishes a book under a false or feigned name; as cryptonymus is given to him who publishes one under a disguised name, and anonymous to him who publishes without any name at all.

**PSEUDOPYRETHRUM**. See **PTARMICA**.

**PSHAW!** An expression or interjection of contempt.

**PSIADIA**, in botany, a genus of the class syngenesia, order polygamia æqualis. Receptacle naked; down simple, sessile; calyx imbricate, ovate; florets of the ray abbreviated. One species; an erect shrub of Mauritius with corymbed flowers.

**PSIDIUM**. Guava. In botany, a genus of the class icosandria, order monogynia. Calyx five-cleft, superior; petals five; berry one or four-celled, many-seeded. Eight species; natives of the East and West Indies and South America. The two following are cultivated.

1. *P. pomiferum*. Red, or apple-guava. Trunk thick, twenty feet high, branchy; bark smooth; leaves oblong-lanceolate, pubescent underneath; peduncles three-flowered; petals large and white; fruit pomegranate-shaped, crowned, when ripe having an agreeable fragrance. A native of both the Indies.

2. *P. pyriferum*. White or pear-guava. Size that of a moderate apple-tree; bark smoothish, yellow-brown with ash-coloured spots; branchy; wood very hard and tough, used for ox-yokes and other articles of agriculture; leaves elliptic, pubescent beneath; peduncles one-flowered; flower white and fragrant; fruit about the size of a hen's egg; pulp rather firm, full of bony seeds, flesh-coloured, aromatic, and agreeable. A native of both the Indies. The apple kind is most cultivated in the Indies, on account of the pulp having a fine acid flavour, whereas the pear species is sweet, and therefore not so agreeable in warm climates. Of the inner pulp of either the inhabitants make jellies, and of the outer rind they make tarts, marmalades, &c. The latter they also stew and eat with milk, and prefer them to any

other stewed fruits. They have an adstringent quality, which exists also in every part of the tree, and abundantly in the leaf buds, which are occasionally boiled with barley and liquorice, as an excellent drink against diarrhæas. A simple decoction of the leaves, used as a bath, is said to cure the itch and most cutaneous eruptions.

These plants are increased by seeds, which must be procured from their native soil; they must be sown in pots, filled with rich kitchen garden earth, plunged into a tan-bed.

**PSILOTUM**, in botany, a genus of the class cryptogamia, order filices. Capsules globular, about three-grained, scattered, axillary, lateral, sessile, three-celled, opening by three valves at top; seeds very numerous. Two species; exotic ferns.

**PSITTACUS**. Parrot. In zoology, a genus of the class aves, order picæ. Bill hooked; upper mandible moveable, (mostly) covered with a cere; nostrils rounded, placed in the base of the bill; tongue fleshy, obtuse, entire; feet formed for climbing.

There are 170 species, thus subdivided:

A. Tail long, wedge-shaped.

B. Tail short, equal at the end, including the cockatoos and lorries generally, but not altogether.

Of all foreign birds, this genus is the best known in Europe: from its docility, and the beauty of its plumage, it has been imported in great numbers, and in those countries where it is indigenous, it is the most numerous of all the feathered tribes. The parrot is an intra-tropical bird, and is found from twenty-four to twenty-five degrees on either side of the equator. Although it lives in the temperate climates of Europe, yet it does not frequently breed there; and its spirits and longevity are diminished in a temperature so little suited to the warmth of its constitution. Parrots are so various in size, and in the shades and distributions of their colours, that it is utterly impossible for language to follow these countless gradations, and the task, though it could be accomplished, would neither prove instructive nor entertaining.

It is remarkable, that of the different species of parrots that are known and described, there is not one common to the New and the Old World. Something like this is observable also in the case of quadrupeds; none of those belonging to the tropical regions in the one continent being discoverable in the same latitudes of the other. No animal that is incapable of bearing the rigours of cold is found to pass from the Old to the New World, because it is only in the regions of the north that these are ascertained approximate. Notwithstanding its attribute of flight, the parrot is incapable of traversing that vast space which lies between Africa and the East Indies; and all the different tribes of this large class remain confined to their primitive stations on each hemisphere. So short and heavy indeed are their flights, that they can hardly cross an arm of the sea seven or eight leagues broad; hence, almost every

island in the West Indies is distinguished by a race of parrots peculiar to itself.

Man has always most admired those animals that seemed to participate most largely of his own nature. The monkey, by its resemblance to his external form, and the parrot by imitating his voice, have excited his wonder, and been deemed a peculiar and privileged race, destined to fill up the intermediate space between him and the brute creation. Savages, who are in general so insensible to the grand spectacle of nature, have viewed these animals with astonishment and delight. They stop their canoes for hours together, to behold the gesticulations of the monkey; and they take such pleasure in taming and educating parrots, that they are said by Buffon to possess the secret of enriching and varying the hue of their plumage; an art to which the more civilized nations of Europe are still strangers.

The Greeks at first knew only one species of parrot, which was imported from the east by one of the captains of Alexander's fleet. Aristotle, the father of naturalists, speaks of it as a rare bird, of which he had only heard by report. The beauty of parrots, and their faculty of speech, soon made them objects of high request among the luxurious Romans, whom the virtuous Cato justly reproaches for this puerile attachment. In his time, they kept them in cages of silver and of ivory, and bought them at a price as high as that of a slave. Till the time of Nero, however, they knew no other species than the Indian, when those who ministered to the pleasures of that extravagant and luxurious emperor found them in an island far up the river Nile, called Gaganda.

The Portuguese, who first doubled the Cape of Good Hope, found all the coast of Africa, and the islands of the Indian ocean, peopled with various tribes of parrots totally unknown in Europe, and in such vast numbers, that it was with difficulty they could be prevented from devouring the rice and maize. These, however, were far inferior to the numbers and variety that presented themselves to the first adventurers in the New World: some of the islands there were called the Parrot isles, from the prodigious quantity of these birds which flocked upon them. They constituted the first article of commerce, between the inhabitants of the Old and New Continents. In these regions every forest swarms with them; and the rook is not better known in Europe than the parrot in the East and West Indies.

The genus of parrots, which comprehends such infinite varieties, may easily be discriminated from every other tribe by the formation of the bill. The upper mandible, as well as the lower, in the whole race is moveable. It is not connected, and in one piece with the skull, as in most other birds, but is joined to the head by a strong membrane on each side, that lifts and depresses it at pleasure. By this contrivance, the bird can open its bill wider than it could otherwise do, and thus receive large nuts and fruits, which it can break with great facility.

## PSITTACUS.

The toes of parrots display also a peculiar conformation : when walking, two are placed before, and one behind ; but when employed to carry food to the bill, one of the back toes is occasionally brought forward. Both the beak and claws of the parrot are used in climbing, an exercise in which the animal appears singularly awkward : the tongue somewhat resembles that of a man ; and it is from this circumstance, that some allege it is so well qualified to imitate the human speech. The formation of the throat, however, and the cavity of the beak, all contribute to its articulation, and to confer on it this distinguished privilege.

Parrots in their wild state feed on almost every kind of fruit and grain. Their flesh, it is said, always contracts the peculiar taste and flavour of the food they eat. At the season when the guava is ripe they are fat and tender, and some of the small tribes of the parrakeet are then sought after by the savages as delicate food. If they feed upon the seeds of the acajou, their flesh acquires the flavour of garlic ; when fed upon the seeds of the spicy trees, their flesh tastes of cloves and cinnamon. The seed of the cotton tree intoxicates them, as well as wine and the smoke of tobacco, which in taming, are often employed, to soften their fierceness and render them more talkative. Their appetite for flesh is unnatural, and when gratified, never fails to bring on diseases. Of all foods, they are fondest of the carthamus or bastard saffron ; which, though of a strongly purgative quality to man, agrees perfectly with their constitution, and will fatten the Guinea parrot very quickly.

Birds of this tribe are subject to disorders unknown to the rest of the feathered tribes ; many of them die of the epilepsy and the gout. They are, however, remarkable for longevity ; and there are some well-attested instances of their having lived from fifty to sixty years. From twenty to thirty years, however, may be considered as the common period which these birds live, when well kept : after which time the bill becomes generally so much hooked, that they are deprived of the power of taking food. They commonly breed in the hollow parts of old trees which have begun to rot, without forming a nest ; and sometimes availing themselves of the labours of the woodpecker, they seize upon the hole which it has industriously scooped out. The larger kinds lay only two eggs, but they bring forth twice in the year. The smaller kinds, which from their weakness are more exposed to devastation, are probably more prolific ; for nature constantly replenishes those species which are most easily destroyed, by conferring upon them a superior degree of fecundity.

As it is only when the parrots are taken young that they can be successfully tamed, the savages commonly take them while in the nest. They sometimes, however, catch them when full grown, for food, and for their feathers, which they convert into valuable articles of dress. For this purpose, they have various

contrivances. They sometimes mark the trees upon which they perch, and during night bring sulphureous substances, which they burn around them, and by the fumes of which the birds are suffocated, and fall to the ground. In some places they stun them with arrows wrapped at the point with cotton ; in others, they cut down the tree in which the nest is built. In New Spain, where the feathers constitute an article of regular commerce among the natives, they take possession of a number of trees where the parrots breed, and which they transmit as an inheritance from father to son.

Independently of the division of this numerous genus into those with long and those with short tails, Buffon and some other naturalists have separated them into those of the Old and those of the New Continent. The former have been subdivided into cockatoos, parrots, lories, and paroquets ; the latter into aras or maccaws, amazons, criks, popinjays, and paroquets. These sections differ chiefly in point of size, growing smaller in the order in which they are mentioned. We shall not puzzle the reader, by attempting to discriminate all these, but shall select for his notice a few of the most remarkable of each tribe.

1. *P. cristatus*. Yellow-crested cockatoo. White ; crest folding ; yellow ; bill and feet black ; a shade of yellow under the wings and tail. The yellow crest, which is of a beautiful citron, consists of a tuft of long soft feathers, which it can raise or depress at pleasure : it is that bird whose beauty and elegance Aldrovandus admires so much : its manners are gentle, and its temper docile ; and it is more distinguished by affection, when tame, than any of the tribe. The cockatoos are the largest parrots of the Old Continent. They are found in all the tropical regions of India, and in the islands of the Indian ocean ; where they are in some parts almost domestic, and build on the roofs of houses. The name cockatoo is given them from its resemblance to their cry. They abound in Bunda, Ceram, the Philippines, and the islands of Sunda. Eighteen inches long : crest five.

2. *P. aterrimus*. Black cockatoo. Black : crest large, paler ; cheeks red, naked. Of the cockatoos, the largest kind of parrots known, there are five species, which are all distinguished by a crest of feathers above the head, and, by the French naturalists are named according to the colour of their crests. The crest of the first is white ; that of the second, yellow, as described above ; that of the third, red ; that of the fourth, pale brown ; and that of the fifth, which is the present, deep brown approaching to black. The whole body of this bird is covered with a black plumage. Its bill and legs are nearly of the same colour ; so that it may be termed the negro of the cockatoos. Some naturalists have described it by the name of the Indian crow. Its length is more than a yard. It is found chiefly in New Holland.

3. *P. erythacus*. Hoary parrot, or jaco. Hoary : temples naked, white : tail cochineal. Several other varieties, from variety of colours.

## PSITTACUS.

This parrot is most frequently imported into Europe at present; and when properly taught, it is a great adept in language. The name jaco, which it frequently pronounces, is commonly given it for that reason. The whole body is of a beautiful grey pearly colour; deep upon the back, but lighter below, and whitening towards the belly. The red vermilion tail is always powdered with a whiteness which preserves its gloss. The beak is black, the feet grey: the iris of a golden hue. The whole length of the bird is about twenty inches. Inhabits Guinea, and the interior parts of Africa. They have been imported into Jamaica, but are not indigenous in any part of the New World. They are not only endowed with the faculty of imitating the human voice, but apparently with a strong desire of speaking, which they manifest by their eagerly listening to catch sounds, and their constant efforts to repeat them. They seem to prescribe themselves tasks, in order to retain the lessons which are given them every day. Cardan absurdly ascribes this to emulation, and a desire of glory.

4. *P. garrulus*. Ceram, or scarlet lory. Red; orbits ash; cheeks and wings green; latter half of the tail-feathers blue. Three or four other varieties, from variety of colour. The name of lory has been given to one family of the parrots, from their frequently repeating this word. The tribe is but little distinguished from the rest, except in colour, which is red, more or less deeply shaded. They are the most spirited and gay of the whole race; qualities which they retain even in captivity. The scarlet lory, and the tribe in general, come from the Moluccas. They are held in such estimation in some parts of India, that they bring a considerable price. The Dutch were long unsuccessful in transporting this elegant species into Europe: they generally died in the passage; and it was with difficulty they brought one alive to Amsterdam, in their second voyage. They are now frequently seen, and are characterised by their attachment to their masters. In Java, the Indians rear vast numbers of them in a state of domestication; a practice which seems very old in the East.

5. *P. Guineensis*. Yellow-breasted lory. Head and neck scarlet; eye-brows and breast yellowish; wings yellow-green tipped with blue. Found chiefly in New Guinea, and in the Molucca isles. It is docile and familiar in its manners when tamed; but peculiarly delicate and difficult to rear. There is none of the whole tribe more easily taught to speak: on this account, as well as the beauty of its plumage, it is held in high estimation; and a single bird has been sold at twenty guineas. Ten inches long.

6. *P. Alexandri*. Alexandrine paroquet. Green; collar and crest red; chin black. Five or six other varieties, from variation in the colours, chiefly in the colour of the collar. The term paroquet has been applied to the smallest of the parrot tribes, whether in the

New or Old Continent. Buffon, who has endeavoured to enumerate the whole of this numerous and diversified race, has termed the small parrots of the Old World perruches, those of America perriches: the former he has subdivided into two sections, those with short, and those with long tails. In the first of these sections he enumerates and describes eighteen species, and in the second ten. These species, however, make but a small number compared with those of other ornithologists, or even with those he has himself enumerated as belonging to America.

The Alexandrine paroquet was the only parrot known, in the time of Pliny, to the ancient Romans. The whole plumage of this species is a brilliant green, except a semicircular band of bright red around the upper part of the neck. The minute description which Aldrovandus has given of the ancient parrot leaves no room to doubt that it is the individual now under review. It is found not only in the interior parts of the south of Asia, but likewise in the island of Ceylon: and it appears that it was from this island that the sailors of Alexander's fleet imported this bird into Greece, where none of the species had ever yet been beheld.

7. *P. Macao*. Red and blue maccaw. Red; quill feathers above blue, beneath rufous; feathers of the shoulders variegated blue and green; cheeks naked, wrinkled. Of all the parrot race, this is the grandest and most magnificently equipped. The purple, the gold, and the azure of his plumage, alternately dazzle the eye of the beholder. The steady assurance of his countenance, the majestic stateliness of his gait, which borders on disdain, seem to announce an inward consciousness of his superior beauty. Parrots of this species are confined to the continent and islands in the intratropical regions of the New World. None of them are to be found either in Africa or the East Indies.

When these parrots were first brought into Europe, their beautiful plumage and their large and majestic form created universal admiration. Aldrovandus first saw one of them at Mantua in 1572; and he observes, that they were at that time in all the estimation which rarity could give them. Princes gave and received them as the most valuable presents.

Columbus in his second voyage saw several of them as he touched at Guadaloupe. They are to be met with even on the desert islands; and they every where constitute the most beautiful ornament of those gloomy forests that darken the face of a country abandoned by men. While Anson and his officers were contemplating the grand scenes displayed by nature in these solitary abodes, a flight of maccaws passed above them; and, as if to heighten the magnificence of the spectacle, they made several windings through the air, displaying the vivid lustre of their plumage. There are four different species of the maccaw described by naturalists; the red, the blue, the green, and the

## PSITTACUS.

black. The characters which distinguish them from the other families of this genus are, first, their size, which is nearly double that of any other species; and next, the length of the tail, which seems beyond even the proportion of their bodies; and lastly, the naked skin, of a dirty white, that covers their cheeks and the under parts of their head.

The red and blue maccaw is nearly three feet in length; the whole body, except the wings, is of a vermilion colour; the larger feathers of the wing are of a deep blue on the outside; on the inner, of a brown leather colour: the lesser feathers are of a blue and green, admirably blended together. The greater coverts of the wings are of a golden yellow terminating in green. On the first discovery of America, these birds, as indeed almost every other kind, were so remarkably tame, that they could almost be taken with the hand. The noise of a fowling piece did not much terrify them. This was also the case in the woods of New Zealand, when visited by captain Cook, where the birds suffered the approach of man with a kind of confidence and familiarity. The savages, few in number, and badly armed, had scarcely made them feel the dominion of the human race.

Birds of this species are found over all the southern parts of America, and the West Indies. They prefer moist and watery grounds, because in such the palm trees are most frequent, of the fruit of which they are passionately fond. They commonly go in pairs, seldom in flocks: sometimes, however, they assemble in the morning in much greater numbers, when they set up a loud and disagreeable chattering, which is heard at a great distance. They cry while on wing, as well as when they perch. Though excellent flyers, they seldom remove far from the place of their abode, except in quest of food; and, when that is obtained, they regularly return in the evening. There is a certain poisonous kind of fruit which they sometimes eat, that is said to communicate its noxious qualities to their flesh, and to render it dangerous to eat them. In Guiana and Brasil, where they are not obliged to take this species of food, they are eat by the natives with great safety.

All the aras, or large parrots, build their nests in the hollow of rotten trees, which, in their native country, are easily to be found; for there, a much greater number of trees fall merely from age than by the hands of the carpenter. When the tree is not fully rotten, and the hole not large enough for their reception, they widen it with their bills. The last process in finishing their house is the lining it with feathers.

The maccaw lays twice in the year, and generally two eggs at a time, about the size of a pigeon's.

The male and female maccaw share alternately in the labours of incubation, and rearing the young. They are equally assiduous in procuring them food; and, during the whole time

of their nonage, the nuptial tie remains unbroken, both parents guarding their offspring with unremitting care.

Maccaws, when young, are easily tamed, and therefore, in many parts of America, they are only caught at that age; because those who catch them are sensible, that all their labour in their education would, after such period, prove fruitless. Du Tertre mentions, however, a singular method of taking the old ones alive practised in the West Indies. The inhabitants watch the moment when they alight to eat the fruit that has fallen; they then surround them, and by clapping their hands and uttering loud shrieks, so alarm them, that, forgetting the use of their wings, they tumble upon their backs to defend themselves by their claws and beak. In the moment of surprise, the savages present to them a stick, which they seize with their claws, when they immediately lay hold of them. These facts, to say no more, appear suspicious, because it is certain these birds fly at the sight of a man; and if so, they will not certainly lie down to listen to his cries.

Another author affirms, that the Indians of the Isthmus of Panama tame maccaws as we tame pies, by allowing them some liberty by day, certain that they will return at night. But however good domestics, they are not adepts in speaking. The savages adorn themselves with their feathers, by drawing them through the cartilage of the nose. Of all game, these birds are most frequent. They make excellent soup, and are very frequently eat in Cayenne.

This species, perhaps, more than any other of the feathered race, is subject to epilepsy; a disorder which is more violent and fatal in warm than in temperate climates. The savages pretend to have found out a cure for this disease, which consists in cutting off the extremity of one of the bird's toes, and allowing the blood to flow.

To this disease the parrots that are kept in a domesticated state are more subject than the wild. The abstraction of the female, the superabundance of food, and the consequent excess of blood in the system, seem to be the causes of epilepsy among these birds.

8. *P. æstivus*, Amazon or common parrot. Green, slightly spotted with yellow; front blue; shoulders blood-red; orbits carnation. Eight or nine other varieties. This parrot is classed among those which are called amazons in America, because they came originally from Amazonia. The criks are nearly allied to the amazons; both are distinguished by the redness of their wings; the wings of the former are red on the top, those of the latter, nearer the body. The amazons are larger than the criks, and much more beautiful.

The body of this species is green, tending to a clay colour below. The feathers on the crown of the head are pale yellow; the cheeks and throat of a clay colour. The five middle feathers of the wing are red down to the middle. The rectrices, or tail feathers, are red in

the half next the body; in the other part, green, terminating in a clay colour.

Birds of this species build in the hollows of rotten trees, that have been prepared by the woodpecker. When their residence in a tree is once fixed, they do not, like other birds, readily abandon it, when their nest is discovered, or their eggs handled. In the season of procreation, they build in great numbers, in the same district, from which they issue in troops to procure food.

When satisfied with food, they begin a kind of loud loquacity, which they continue without interruption, hopping from branch to branch, till the darkness of night, and the fatigue of continual motion, compel them to rest. When the common parrots are taken young, their education is most successful: after they have arrived at their adult state, they can hardly be tamed to such a degree as to suffer themselves to be handled. The method fallen upon to tame them is by making them snuff the smoke of tobacco, which so intoxicates them, that they become gentle, languid, and inactive. As soon as their vicious habits begin to return, the dove is repeated; and the same treatment completely checks their noisy jargon.

The amazons and criks are, of all the American parrots, most easily taught to speak. The females have been alleged to be incapable of acquiring that art, but without any truth; for they are even more docile and gentle than the males.

9. *P. ochrocephalus*. Yellow-headed parrot. Head and throat are yellow: upper part of the body a shining green, lower yellow: distinguished from the amazons by the yellow tip of the wing. First row of the wing coverts red and yellow; the others a fine green: feathers of the tail and wings variegated with green, black, yellow, red, and violet.

This species belongs to the class called criks by the French writers. M. Bougot, a capuchin, has transmitted the following detail of the manners and habits of this bird to M. Buffon. "It shews itself," says he, "capable of attachment to its master; but its affection is always conditional, and in proportion to the caresses it receives; it is piqued by neglect, and vindictive if provoked. It falls into transports of anger, bites its enemy, then laughs aloud, as if applauding itself for the mischief it has done. Against harsh treatment and chastisement it constantly revolts, being always hardened and rendered more obstinate by severity.—An incessant habit of gnawing and tearing makes these birds destructive of every thing around them. Cloths, furniture, paper, and pens they take a pleasure in tearing and destroying; and you no sooner remove these articles to a different place, to put them out of their way, than they are there, merely from a principle of contradiction. These bad qualities, however, are compensated by others more agreeable: they easily retain what instructions are given them in speaking. Before they begin to articulate, they mount upon the beam of their cage, hang

their wings, and shake themselves. Confinement makes them pensive and silent; they are most talkative when at liberty, and in summer they chatter more copiously than in winter; it is then that their love of conversation seems to overcome their appetite for food.

"In these seasons of gaiety, they are affectionate, obedient, and attentive; they are fond to give and receive caresses; but their good humour is often interrupted by sudden gusts of anger and caprice. They seem to be affected by the changes of the weather; for by these they become silent and melancholy.

"This bird is fond of children; a circumstance in which he differs from other birds of the same genus: he prefers, however, some to others; and the favourite child has the privilege of taking hold of him and carrying him at pleasure. He caresses them; but did a grown person then venture to touch him, he would bite him most severely. When his young friends leave him, he shows evident symptoms of distress; follows them, and calls them back with a loud voice.

"The time of moulting is with this species a season of dejection and distress, which continues with little abatement for three months. Their ordinary food is nuts, fruit, and bread dipped in wine: they prefer flesh to grain, but it makes them heavy and indolent, and often causes them to throw their feathers. Their food is deposited for some time in a pouch or bag, from which it is afterwards taken to undergo rumination."

10. *P. Paradisi*. Paradise parrot. Next to the families of amazons and criks, is a tribe of popinjays, of which the parrot of paradise is a species. There are eleven species of the popinjays, which are all distinguished from the tribes above described, by having no red on their wings. This particular kind is very beautiful. The whole body is yellow, and all the feathers bordered with a sort of gilding. The larger feathers of the wing are white; the lateral feathers of the tail red about two thirds of their length, the rest yellow.

11. *P. aureus*. Golden-crowned parrot. The class of paroquets is extremely numerous and diversified. Of the species named golden-crowned by Mr. Edwards, an individual, in his time, remained fourteen years in England, and laid five or six small white eggs. Paroquets of this species assemble in very large flocks in Cayenne: when properly tamed, they are good speakers. These beautiful birds have a large spot of orange colour on their forehead; the rest of the head, the back, wings, and tail, are of a deep green. The throat and lower part of the belly yellow; on each wing a longitudinal stroke of fine blue.

PSOAS MAGNUS. (Loas, from *Loas*, the loin; because it is situated in the loins.) In anatomy, *psaos*, seu *lumbicus internus* of Winslow. This is a long, thick, and very considerable muscle, situated close to the fore part and sides of the lumbar vertebræ. It arises from the bodies of the last vertebra of the back, and

of all the lumbar vertebræ laterally, as well as from the anterior surfaces of their transverse processes, by distinct tendinous and fleshy slips, that are gradually collected into one mass, which becomes thicker as it descends, till it reaches the last of the lumbar vertebræ, where it grows narrower again, and, uniting at its outer and posterior edge, (where it begins to become tendinous) with the iliacus internus descends along with that muscle under the ligamentum fallopii, and goes to be inserted tendinous at the bottom of the trochanter minor of the os femoris, and fleshy into the bone a little below that process. Between the tendon of this muscle and the ischium, we find a considerable bursa mucosa. This muscle, at its origin, has some connection with the diaphragm, and likewise with the quadratus lumborum. It is one of the most powerful flexors of the thigh forwards, and may likewise assist in turning it outwards. When the inferior extremity is fixed, it may help to bend the body forwards, and in an erect posture, it greatly assists in preserving the equilibrium of the trunk upon the upper part of the thigh.

**PSOAS PARVUS.** This muscle, which was first described by Riolanus, is situated upon the *psaos magnus*, at the anterior part of the loins. The *psaos parvus* arises thin and fleshy from the side of the uppermost vertebra of the loins, and sometimes also from the lower edge of the last vertebra of the back, and from the transverse processes of each of these vertebræ; it then extends over part of the *psaos magnus*, and terminates in a thin flat tendon, which is inserted into that part of the brim of the pelvis where the os pubis joins the ilium. From this tendon a great number of fibres are sent off, which form a thin fascia, that covers part of the *psaos magnus* and *iliacus internus*, and gradually loses itself on the fore part of the thigh. In the human body, this muscle is very often wanting; but in a dog, according to Douglas, it is never deficient. Riolanus was of opinion, that it occurs oftener in men than in women; Winslow asserts just the contrary; but the truth seems to be, that it is as often wanting in one sex as in the other. Its use seems to be to assist the *psaos magnus* in bending the loins forward; and when we are lying upon our back, it may help to raise the pelvis.

**PSOPHIA.** Trumpeter. In zoology, a genus of the class aves, order grallæ. Bill cylindrical, conic, convex, somewhat pointed, the upper mandible longer; nostrils oval, pervious; tongue cartilaginous, flat, fringed at the tip; feet four-toed, cleft. Two species.

1. *P. crepitans*. Cold-breasted trumpeter. Black; back grey; breast shining blue-green; orbits naked, red; bill yellowish-green; legs strong, tall, brownish ash or green; beneath the back toe a short protuberance, a little distance from the ground; tail very short; feathers of the head downy, of the lower part of the neck squamiform, of the shoulders ferruginous, lax, pendulous, silky; scapulars long,

pendent. Inhabits Brasil and Guinea. Twenty inches long; emits from the lungs a harsh, uncommon noise, not unlike a child's trumpet, and follows people through the streets persecuting them with its disagreeable cry, so that it is difficult to get rid of them; stands on one leg, and sleeps with its neck drawn in between the shoulders; eggs blue-green.

2. *P. undulata*. Undulate trumpeter. Crest of the hind-head short, whitish; of the breast long, black, pendent; head brown with black spots; body above brown waved with black, beneath blueish-white; breast and belly with a few black spots; on each side of the neck a black stripe, widening as it descends, and meeting on the lower part before. Inhabits Africa: size of a goose. See Nat. Hist. Pl. CLXI.

**PSORA.** (*Ψωρα*, the itch.) The itch. A genus of disease in the class locales and order dialyses of Cullen: appearing first on the wrists and between the fingers in small pustules with watery heads. It is contagious.

**PSORALEA.** in botany, a genus of the class diadelphia, order decandria. Calyx as long as the legume; stamens with one of the filaments separate; legume one-seeded, slightly-beaked, valveless. Twenty-nine species, mostly Cape plants. The following are cultivated chiefly:

1. *P. pinnata*. Wing-leaved psoralea. Stem woody, branching out five or six feet high; leaves pinnate in two pairs, linear; peduncles one-flowered; flowers sessile, blue with white heels. Cape.

2. *P. aculeata*. Prickly psoralea. Stem shrubby, branchy, three or four feet high; leaves ternate; leaflets wedge-form with recurved points; flowers axillary, solitary, close together, of a blue colour. Cape.

3. *P. bituminosa*. Bituminous psoralea. Stalk shrubby, few branches; about three or four feet high; leaves ternate; spikes in heads, axillary, peduncled; flowers blue. Italy, Sicily.

The following are also cultivated:

4. *P. bracteata*. Oval-spiked psoralea.

5. *P. hirta*. Hairy psoralea.

6. *P. americana*. American psoralea.

7. *P. corilifera*. Hazel-nut-leaved psoralea.

8. *P. dalea*. Annual psoralea.

These are all increased by sowing their seeds in the early spring months on a moderate hot-bed, or in pots plunged into it. They may also be increased by planting cuttings of the young shoots, in summer, in pots filled with light earth plunged into a hot-bed, and covered with glasses.

**PSORIASIS.** (*Ψωρίασις*, from *Ψωρα*, to itch.) The disease to which Dr. Willan gives this title is characterized by a rough and scaly state of the cuticle, sometimes continuous, sometimes in separate patches, of various sizes, but of an irregular figure, and for the most part accompanied with rhagades or fissures of the skin. From the lepra it may be distinguished, not only by the distribution of the patches, but

## PSORIASIS.

also by its cessation and recurrence at certain seasons of the year, and by the disorder of the constitution with which it is usually attended. Dr. Willan gives the following varieties: *Psoriasis guttata*,—*diffusa*,—*gyrata*,—*palmaria*,—*labialis*,—*infantilis*,—*inveterata*.

*Psoriasis guttata*. This complaint appears in small, distinct, but irregular patches of laminated scales, with little or no inflammation round them. The patches very seldom extend to the size of a sixpence. They have neither an elevated border, nor the oval or circular form by which all the varieties of lepra are distinguished; but their circumference is sometimes angular, and sometimes goes into small serpentine processes. The scale formed upon each of them is thin, and may be easily detached, leaving a red, shining base. The patches are often distributed over the greatest part of the body, but more particularly on the back part of the neck, the breast, arms, loins, thighs, and legs. They appear also upon the face, which rarely happens in lepra. In that situation they are red and more rough than the adjoining cuticle, but not covered with scales. The *psoriasis guttata* often appears on children in a sudden eruption, attended with a slight disorder of the constitution, and spreads over the body within two or three days. In adults it commences with a few scaly patches on the extremities, proceeds very gradually, and has a longer duration than in children. Its first occurrence is usually in the spring season, after violent pains in the head, stomach, and limbs. During the summer it disappears spontaneously, or may be soon removed by proper applications, but is apt to return again early in the ensuing spring, and continues so to do for several successive years. When the scales have been removed, and the disease is about to go off, the small patches have a shining appearance, and they exhibit a dark red intermixed with somewhat of a bluish colour for many days or even weeks before the skin is restored to its usual state. In the venereal disease there is an eruption which very much resembles the *psoriasis guttata*, the only difference being a slight degree of scalliness, and a different shade of colour in the patches, approaching to a livid red, or very dark rose colour. The patches vary in their extent, from the section of a pea, to the size of a silver penny, but are not exactly circular. They rise at first very little, if at all, above the cuticle. As soon, however, as the scales appear on them, they become sensibly elevated; and sometimes the edge or circumference of the patch is higher than the little scales in its centre. This eruption is usually seen upon the forehead, breast, between the shoulders, or in the inside of the fore-arms, in the groins, about the inside of the thighs, and upon the skin covering the lower part of the abdomen. The syphilitic *psoriasis guttata* is attended with, or soon followed by, an ulceration of the throat. It appears about six or eight weeks after a chancre has been healed by an ineffectual course of mercury. A similar appearance takes place at nearly the same pe-

riod, in some cases where no local symptoms had been noticed. When a venereal sore is in a discharging state, this eruption, or other secondary symptoms, often appear much later than the period above mentioned. They may also be kept back three months, or even longer, by an inefficient application of mercury. If no medicines be employed, the syphilitic form of the *psoriasis guttata* will proceed during several months, the number of the spots increasing, and their bulk being somewhat enlarged, but without any other material alteration.

The *psoriasis diffusa* spreads into large patches, irregularly circumscribed, reddish, rough, and chappy, with scales interspersed. It commences, in general, with numerous minute asperities, or elevations of the cuticle, more perceptible by the touch than by sight. Upon these, small distinct scales are soon after formed, adhering by a dark central point, while their edges may be seen white and detached. In the course of two or three weeks all the intervening cuticle becomes rough and chappy, appears red, and raised, and wrinkled, the lines of the skin sinking into deep furrows. The scales which form among them are often slight, and repeatedly exfoliate. Sometimes, without any previous eruption of papulæ, a large portion of the skin becomes dry, harsh, cracked, reddish, and scaly, as above described. In other cases, the disorder commences with separate patches of an uncertain form and size, some of them being small, like those in the *psoriasis guttata*, some much larger. The patches gradually expand till they become confluent, and nearly cover the part or limb affected. Both the *psoriasis guttata* and *diffusa* likewise occur as a sequel of the lichen simplex. This transition takes place more certainly after frequent returns of the lichen. The parts most affected by *psoriasis diffusa* are the cheeks, chin, upper eye-lids, and corners of the eyes, the temples, the external ear, the neck, the fleshy parts of the lower extremities, and the fore-arm, from the elbow to the back of the hand, along the supinator muscle of the radius. The fingers are sometimes nearly surrounded with a loose scaly incrustation; the nails crack and exfoliate superficially. The scaly patches likewise appear, though less frequently, on the forehead and scalp, on the shoulders, back, and loins, on the abdomen, and instep. This disease occasionally extends to all the parts above-mentioned at the same time; but, in general, it affects them successively, leaving one place free, and appearing in others; sometimes, again, returning to its first situation. The *psoriasis diffusa* is attended with a sensation of heat, and with a very troublesome itching, especially at night. It exhibits small, slight, distinct scales, having less disposition than the lepra to form thick crusts. The chaps or fissures of the skin, which usually makes a part of this complaint, are very sore and painful, but seldom discharge any fluid. When the scales are removed, by frequent washing,

## PSORIASIS.

or by the application of unguents, the surface, though raised and uneven, appears smooth and shining; and the deep furrows of the cuticle are lined by a slight scalliness. Should any portion of the diseased surface be forcibly excoriated, there issues out a thin lymph, mixed with some drops of blood, which slightly stains and stiffens the linen, but soon concretes into a thin dry scab; this is again succeeded by a white scalliness, gradually increasing, and spreading in various directions. As the complaint declines, the roughness, chaps, scales, &c. disappear, and a new cuticle is formed, at first red, dry, and shrivelled, but which, in two or three weeks, acquires the proper texture. The duration of the psoriasis diffusa is from one to four months. If, in some constitutions, it does not then disappear, but becomes, to a certain degree, permanent, there is at least an aggravation or extension of it, about the usual period of its return. In other cases, the disease, at the vernal returns, differs much as to its extent, and also with respect to the violence of the preceding symptoms. The eruption is, indeed, often confined to a single scaly patch, red, itching, and chapped, of a moderate size, but irregularly circumscribed. This solitary patch is sometimes situated on the temple, or upper part of the cheek, frequently on the breast, the calf of the leg, about the wrist, or within, and a little below the elbow joint, but especially at the lower part of the thigh, behind. It continues in any of these situations several months without much observable alteration. The complaint denominated with us the bakers itch is an appearance of the psoriasis diffusa on the back of the hand, commencing with one or two small, rough, scaly patches, and finally extending from the knuckles to the wrist. The rhagades, or chaps and fissures of the skin, are numerous about the knuckles and ball of the thumb, and where the back of the hand joins the wrist. They are often highly inflamed, and painful, but have no discharge of fluid from them. The back of the hand is a little raised or tumefied, and, at an advanced period of the disorder, exhibits a reddish, glossy surface, without crusts or numerous scales. However, the deep furrows of the cuticle are, for the most part, whitened by a slight scalliness. This complaint is not general among bakers; that it is only aggravated by their business, and affects those who are otherwise disposed to it, may be concluded from the following circumstances: 1. It disappears about midsummer, and returns in the cold weather about the beginning of the year: 2. Persons constantly engaged in the business, after having been once affected with the eruption, sometimes enjoy a respite from it for three or four years: 3. When the business is discontinued, the complaint does not immediately cease. The grocers itch has some affinity with the bakers itch, or tetter; but, being usually a pustular disease at its commencement, it properly belongs to another genus. Washerwomen, probably from the irritation of soap, are liable to be affected

with similar scaly disease on the hands and arms, sometimes on the face and neck, which, in particular constitutions, prove very troublesome, and of long duration.

The *psoriasis gyrata* is distributed in narrow patches or stripes, variously figured; some of them are nearly longitudinal; some circular, or semicircular with vermiciform appendages; some are tortuous, or serpentine; others like earth-worms or leeches; the furrows of the cuticle, being deeper than usual, make the resemblance more striking, by giving to them an annulated appearance. There is a separation of slight scales from the diseased surface, but no thick incrustations are formed. The uniform disposition of these patches is singular; I have seen a large circular one situated on each breast above the papilla; and two or three others of a serpentine form, in analogous situations along the sides of the chest. The back is often variegated in like manner, with convoluted tetter, similarly arranged on each side of the spine. They likewise appear, in some cases, on the arms and thighs, intersecting each other in various directions. A slighter kind of this complaint affects delicate young women and children in small scaly circles or rings, little discoloured; they appear on the cheeks, neck, or upper part of the breast, and are mostly confounded with the herpetic, or pustular ring-worm. The *psoriasis gyrata* has its remissions and returns, like the *psoriasis diffusa*; it also exhibits, in some cases, patches of the latter disorder on the face, scalp, or extremities, while the trunk of the body is chequered with the singular figures above described.

*Psoriasis palmaria.* One very obstinate species of tetter is nearly confined to the palm of the hand. It commences with a small, harsh, or scaly patch, which gradually spreads over the whole palm, and sometimes appears in a slighter degree on the inside of the fingers and wrist. The surface feels rough from the detached and raised edges of the scaly laminae; its colour often changes to brown, or black, as if dirty; yet the most diligent washing produces no favourable effect. The cuticular furrows are deep, and cleft at the bottom longitudinally, in various places, so as to bleed on stretching the fingers. A sensation of heat, pain, and stiffness, in the motions of the hand, attends this complaint. It is worst in winter or spring, and occasionally disappears in autumn or summer, leaving a soft dark-red cuticle; but many persons are troubled with it for a series of years, experiencing only very slight remissions. Every return or aggravation of it is preceded by an increase of heat and dryness, with intolerable itching. Shoemakers have the *psoriasis palmaria* locally, from the irritation of the wax they so constantly employ. In braziers, tinmen, silversmiths, &c. the complaint seems to be produced by handling cold metals. A long predisposition to it from a weak, languid, hectic state of the constitution may give effect to different occasional causes. Dr. Willan has observed it in women after lying-in; in some

persons it is connected, or alternates with arthritic complaints. When the palms of the hands are affected as above stated, a similar appearance often takes place on the soles of the feet; but with the exception of rhagades, or fissures, which seem less liable to form there, the feet being usually kept warm and covered. Sometimes, also, the psoriasis palmaria is attended with a thickness of the præputium, with scaliness, and painful cracks. These symptoms at last produce a phymosis, and render connubial intercourse difficult, or impracticable; so great, in some cases, is the obstinacy of them, that remedies are of no avail, and the patient can only be relieved by circumcision. This affection of the præputium is not exactly similar to the venereal appearance; but rhagades or fissures, and indurated patches within the palm of the hand, take place in syphilis, and somewhat resemble the psoriasis palmaria. The venereal patches are, however, distinct, white, and elevated, having nearly the consistence of a soft corn. From the rhagades, there is a slight discharge, very offensive to the smell. The soles of the feet are likewise, in this case, affected with the patches, not with rhagades. When the disease yields to the operation of mercury, the indurated portions of cuticle separate, and a smooth new cuticle is found formed underneath. The fingers and toes are not affected with the patches, &c. in venereal cases.

*Psoriasis labialis.* The psoriasis sometimes affects the prolabium without appearing on any other part of the body. Its characteristics are, as usual, scaliness, intermixed with chaps and fissures of the skin. The scales are of a considerable magnitude, so that their edges are often loose, while the central points are attached, a new cuticle gradually forms beneath the scales, but is not durable. In the course of a few hours it becomes dry, shrivelled, and broken; and, while it exfoliates, gives way to another layer of tender cuticle, which soon, in like manner, perishes. These appearances should be distinguished from the slight chaps and roughness of the lips produced by very cold or frosty weather, but easily removed. The psoriasis labialis may be a little aggravated by frost or sharp winds, yet it receives no material alleviation from an opposite temperature. It is not, indeed, confined within any certain limit, or period of duration, having, in several instances, been protracted through all the seasons. The under lip is always more affected than the upper, and the disease takes place more especially in those persons whose lips are full and prominent.

*Psoriasis scrotalis.* The skin of the scrotum may be affected in the psoriasis diffusa like other parts of the surface of the body; but sometimes a roughness and scaliness of the scrotum appears as an independent complaint, attended with much heat, itching, tension, and redness. The above symptoms are succeeded by a hard, thickened, brittle texture of the skin, and by painful chaps or excoriations, which are not easy to be healed. This complaint is sometimes produced

under the same circumstances as the prurigo scroti, and appears to be in some cases a sequel of it. A species of the psoriasis scrotalis likewise occurs in the lues venerea, but merits no particular attention, being always combined with other secondary symptoms of the disease.

*Psoriasis infantilis.* Infants, between the ages of two months and two years, are occasionally subject to the dry tetter. Irregular, scaly patches, of various sizes, appear on the cheeks, chin, breast, back, nates, and thighs. They are sometimes red, and a little rough, or elevated; sometimes excoriated, then again covered with a thin incrustation; and lastly, intersected by chaps or fissures. The general appearances nearly coincide with those of the psoriasis diffusa; but there are several peculiarities in the tetter of infants which require a distinct consideration.

The *psoriasis inveterata* is characterized by an almost universal scaliness, with a harsh, dry, and thickened state of the skin. It commences from a few irregular, though distinct patches on the extremities. Others appear afterwards on different parts, and, becoming confluent, spread at length over all the surface of the body, except a part of the face, or sometimes the palms of the hands, and soles of the feet. The skin is red, deeply furrowed, or wrinkled, stiff and rigid, so as somewhat to impede the motion of the muscles, and of the joints. So quick, likewise, is the production and separation of scales, that large quantities of them are found in the bed on which a person affected with this disease has slept. They fall off in the same proportion by day, and being confined within the linen, excite a troublesome and perpetual itching.

**PSOROPHTHALMIA.** (Ψωροφθαλμία, from ψωρο, a scab, and οφθαλμος, an eye.) A scabby eruption, or itch-like pustules of the eyelids and their margins. The proximate cause is an acrimony deposited in the glands of the eye-lids. The species of the psorophthalmia are, 1. Psorophthalmia crustosa, which forms dry or humid crusts in the margins of the eye-lids. 2. Psorophthalmia herpetica, in which small papulae, itching extremely, and terminating in scurf, are observed.

**PSYCHE**, a nymph whom Cupid married and carried into a place of bliss. Venus put her to death because she had robbed the world of her son; but Jupiter, at the request of Cupid, granted immortality to Psyche. The word signifies the soul, and Psyche personified is generally represented with the wings of a butterfly, to intimate the lightness of the soul, of which the butterfly is the symbol.

**PSYCOTRIA**, in botany, a genus of the class pentandria, order monogynia. Calyx five-toothed, crowning the berry; corol tubular, berry globular; seeds two, hæmispherical, grooved on the convex side. Thirty-nine species; herbs, shrubs, and trees, of both the Indies and South America.

Of these, *P. emetria* is said to furnish the root known by the name of ipecacuanha in the

shops. A North American plant, herbaceous, procumbent; root perpendicular, wrinkled, slightly branched; leaves lanceolate, glabrous, approximate, opposite, pointed, with a round prominent rib underneath; stipules extrafoliaceous, subulate; heads axillary, peduncled, few-flowered; flowers white, small, sessile.

There is, however, some doubt as to the plant which furnishes the ipecacuanha; for Schoeber has of late asserted it to be the root of a plant which he denominates *callicocca* of Jussieu's order rubiacæ; while others assert one kind, at least, of ipecacuanha to be a *VIOLA*: which see.

**PSYDRACIÆ.** (*ψυδρακία*, from *ψυχος*, cold.) Red and somewhat elevated spots, which soon form broad and superficial vesicles, such as those produced by the stinging nettle, the bites of insects, &c. See **PUSTULE**.

**PSYLLIUM.** (*ψύλλιον*, from *ψύλλος*, a flea; so called because it was thought to destroy fleas.) *Pulicaris herba*. Flea-wort. The seeds of this plant, *plantago psyllium*; caule ramoso herbaceo; foliis subdentatis, recurvatis; capitulis aphyllis of Linnéus, have a nauseous mucilaginous taste, and no remarkable smell. The decoction of the seeds is recommended in hoarseness and asperity of the fauces.

**PTARMICA.** (*πταρμικά*, from *πτειρω*, to sneeze; so called because it irritates the nose, and provokes sneezing.) *Pseudopyrethrum*. *Pyrethrum sylvestre*: *Draco sylvestris*. *Tarchon sylvestris*. *Sternutamentoria*. Sneeze-wort. *Bastard pellitory*. *Achillea ptarmica*; foliis lanceolatis, acuminatis, argute serratis of Linnéus. The flowers and roots of this plant have a hot biting taste, approaching to that of pyrethrum, with which they also agree in their pharmaceutical properties. Their principal use is as a masticatory and sternutatory.

**PTARMIGAN**, in ornithology. See **TE-TRAO**.

**PTELEA**, in botany, a genus of the class tetrandria, order monogynia. Corol four-petalled; calyx four-parted, inferior; stigmas two; fruit with a roundish membrane containing a single seed in the middle.

One species only, *P. nifolea*. Three-leaved ptelea, or shrubby trefoil. Stem upright, woody, ten or twelve feet high; leaves in fives; flowers cymed; polygamous or diceious, of a white hue. It is cultivated by seeds, cuttings, or layers: and has a good effect in shrubberies, or other groups in pleasure-grounds.

**PTERIS**, in botany, a genus of the class cryptogamia, order filices. Fructification in a continued marginal line; involucre from the inflated membranaceous margin of the frond, continued, opening towards the rib. Forty-five species. They may be thus subdivided into sections:

- A. *Pteris* proper.
  - a. Frond simple.
  - b. Frond pinnate.
  - γ. Frond doubly pinnatifid and doubly pinnate.
  - δ. Frond more than decomposed.
- B. *Adiantum*-shaped; with the fructifications

of pteris, and a brown stalk. The root is viscid, nauseous, and bitterish; and like ferns in general has a salt mucilaginous taste. The powder of it is like that of the filix mas, is in some places used as a vermifuge, and in others as an excellent remedy in rachitis. Upon a larger scale it is often employed in its ashes as a manure, or as a substitute for soap.

**PTEROCARPUS**, in botany, a genus of the class diadelphia, order decandria. Calyx five-toothed; legume falcate, foliaceous, varicose, surrounded with a wing, not opening; seeds few, solitary. Seven species; natives of the Indies or South America. The following are the chief:

1. *P. draco*. Dragon's-blood tree. A tree thirty feet high, with a solid white wood; the bark when cut transversely yielding a blood-red resin, which is the dragon's-blood of the shops; a native of the West Indies.

2. *P. marsupium*. Tree with an orange-coloured wood, and white flowers; a native of Coromandel.

3. *P. santalinus*. Red saunders wood. Tree with a deep red wood; leaves ternate, roundish, retuse, quite glabrous, petals crenate, undulate, yellow with red veins.

There is some reason to believe that several red woods, capable of communicating this colour to spirituous liquors, are sold as red saunders; but the true officinal kind appears, on the best authority, to be of this tree, which is extremely hard, of a bright garnet red colour, and bears a fine polish. It is only the inner substance of the wood that is used as a colouring matter, and the more florid red is mostly esteemed. On being cut it is said to manifest a fragrant odour, which is more especially in old trees. According to Lewis, this wood is of a dull red, almost blackish colour on the outside, and a deep brighter red within; its fibres are now and then curled, as in knots. It has no manifest smell, and little or no taste; even of extracts made from it with water, or with spirit, the taste is considerable.

To watery liquors it communicates only a yellowish tinge, but to rectified spirit a fine deep red. A small quantity of an extract made with this menstruum, tinges a large one of fresh spirit of the same colour; though it does not, like most other resinous bodies, dissolve in expressed oils. Of distilled oils, there are some, as that of lavender, which receive a red tincture from the wood itself, and from its resinous extract, but the greater number do not. Red saunders has been esteemed as a medicine; but its only use attaches to its colouring property. The juice of this tree, like that of *P. draco*, affords a species of dragon's blood.

**PTEROCOCEUS.** See **CALLIGONUM**.

**PTEROGONIUM**, in botany, a genus of the class cryptogamia, order musci. Capsule oblong; fringe simple, of sixteen or thirty-two linear, erect, undivided teeth; flowers lateral. Nine species; three of them mosses of our own country.

**PTERONIA**, in botany, a genus of the

class syngenesia, order polygamia æqualis. Receptacle clothed with many-parted chaff; down somewhat feathery; calyx imbricate, with the scales carinate. Twenty-seven species; shrubs of the Cape.

**PTEROPHORUS**, in the entomology of Fabricius, a tribe of the genus *PHALÆNA*, which see.

**PTEROSPERMUM**, in botany, a genus of the class monadelphia; order decandria. Calyx single, five-parted; petals five; stamens twenty, five of them barren; style cylindrical; stigma thickish; capsule woody, five-celled; seeds mingled. Two species; natives of India: one a tree with ferruginous downy branchlets; the other a tree with white woolly bark; leaves white, woolly underneath; flowers white, terminal. The wood of both hard, and very like that of the holly-tree.

**PTEROTRACHIA**, in zoology, a genus of the class vermes, order mollusca. Body detached, gelatinous, with a moveable fin at the abdomen or tail; eyes two, placed within the head. Four species; the residence of one or two unknown, the rest found in the Mediterranean and Archipelago.

**PTERYGIUM**. (*πτερυγιον*, *πτερυξ*, a wing.) A membranous excrescence which grows upon the internal canthus of the eye chiefly, and expands itself over the albuginea and cornea towards the pupil. It appears to be an extension or prolongation of the fibres and vessels of the *caruncula lachrymalis*, or semilunar membrane, appearing like a wing. The species of pterygium are four: 1. *Pterygium tenue*, seu *ungula*, is a pellucid pellicle, thin, of a cineritious colour, and unpainful; growing out from the *caruncula lacrymalis*, or *membrana semilunaris*. 2. *Pterygium crassum*, seu *pannus*, differs from the *ungula* by its thickness, red colour, and fulness of the red vessels on the white of the eye, and it stretches over the cornea like fasciculi of vessels. 3. *Pterygium malignum*, is a pannus of various colours, painful, various, and arising from a cancerous acrimony. 4. *Pterygium pingue*, seu *pinguicula*, is a mollicle-like lard or fat, soft, without pain, and of a light yellow colour, which commonly is situated in the external angle of the eye, and rarely extends to the cornea; but often remains through life.

**PTERYGO**. In anatomy. Names compounded of this word belong to muscles which are connected with the pterygoid or wing-like process of the sphæmoid bone; as, *pterygo-pharyngeus*, &c.

**P. PHARYNGEUS**. See **CONSTRUCTOR PHARYNGIS SUPERIOR**.

**P. STAPHILINUS EXTERNUS**. See **LEVATOR PALATI**.

**PTERYGOIDEUS EXTERNUS**. (from *πτερυξ*, a wing, from its belonging to the processes pterygoides.) *Pterygoideus minor* of Winslow. It is placed, as it were, horizontally along the basis of the skull, between the pterygoid process and the condyle of the lower jaw. It usually arises by two distinct heads; one of which is thick, tendinous, and fleshy, from the outer wing of the pterygoid process of the os

sphenoides, and from a small part of the os maxillare adjoining to it; the other is thin and fleshy, from a ridge in the temporal process of the sphenoid bone, just behind the slit that transmits the vessels to the eye. Sometimes this latter origin is wanting, and, in that case, part of the temporal muscle arises from this ridge. Now and then it affords a common origin to both these muscles. From these origins the muscle forms a strong fleshy belly, which descends almost transversely outwards and backwards, and is inserted tendinous and fleshy into a depression in the fore part of the condyloid process of the lower jaw, and into the anterior surface of the capsular ligament that surrounds the articulation of that bone. All that part of this muscle, which is not hid by the *pterygoideus internus*, is covered by a ligamentous expansion, which is broader than that belonging to the *pterygoideus internus*, and originates from the inner edge of the glenoid cavity of the lower jaw, immediately before the styloid process of the temporal bone, and extends obliquely downwards, forwards, and outwards to the inner surface of the angle of the jaw. When these muscles act together, they bring the jaw horizontally forwards. When they act singly, the jaw is moved forwards and to the opposite side. The fibres that are inserted into the capsular ligament serve likewise to bring the moveable cartilage forwards.

**PTERYGOIDEUS INTERNUS**. *Pterygoideus major* of Winslow. It arises tendinous and fleshy from the whole inner surface of the external ala of the pterygoid process, filling all the space between the two wings; and from that process of the os palati that makes part of the pterygoid fossa. From thence the muscle growing larger, descends obliquely downwards, forwards, and outwards, and is inserted by tendinous and fleshy fibres, into the inside of the lower jaw, near its angle. This muscle covers a great part of the *pterygoideus externus*; and along its posterior edge we observe a ligamentous band, which extends from the back part of the styloid process to the bottom of the angle of the lower jaw. The use of this muscle is to raise the lower jaw, and to pull it a little to one side.

**PTERYGOIDEUS MAJOR**. See **PTERYGOIDEUS INTERNUS**.

**PTERYGOIDEUS MINOR**. See **PTERYGOIDEUS EXTERNUS**.

**PTERYGOID PROCESS**. (from *πτερυξ*, a wing, and *ειδος*, resemblance.) A wing-like process of the sphæmoid bone.

**PTILINUS**, in the entomology of Fabricius, a tribe of the coleopterous genus *HISPA*, which see.

**PTILOISIS**. (*πιλοσις*, from *πιλος*, bald.) A synonym of *madarosis*. See **MADAROSIS**.

**PTINUS**, in zoology, a genus of the class insecta, order coleoptera. Antennas filiform, the last joints larger; thorax nearly round, not margined, receiving the head. Thirty-nine species; a few African or American, the rest European; six or seven, inhabitants of our own country. They are thus subdivided into sections.

A. Feelers clavate; lip entire; constituting the anobium tribe of Fabricius.

B. Feelers filiform; lip bifid; the ptinus of Fabricius.

The following are chiefly worthy of notice:

1. *P. pulsator*. Death-watch. Subvillous, dusky, with irregular, grey, brown spots. Inhabits our own country and Europe generally in old wooden furniture; makes a peculiar ticking with the fore-part of its head, resembling a beating with the nail upon a table; this is done in seven, nine, or eleven distinct strokes in the night-time, and has been considered by vulgar superstition as forerunning some fatal occurrence in the family; it is nothing more, however, than the call of one sex to the other. A quarter of an inch long. There are one or two other insects that make a similar noise, and especially the tick-watch or *termes pulsatorius* with which the death-watch is often confounded. See **TERMES**.

2. *P. pertinax*. Brown, immaculate; thorax compressed. Inhabits Europe, and is very destructive to wooden furniture, and to books; when touched draws in its head and legs, and becomes immovable; is destroyed by the *attelabus fermicarius*.

3. *P. fur*. Testaceous; thorax four-toothed; shells with two white bands. Inhabits Europe, and is exceedingly destructive to museums, books, furniture, preserved subjects of natural history, and dried seeds. Larve six-footed, fat, soft, hairy, ferruginous, the dorsal segments a little prominent, pupa contained in a glutinous follicle; female wingless. See *Nat. Hist.* Pl. CLXVI.

**PTISAN** is properly barley decorticated, or deprived of its hulls by beating in a mortar, as was the ancient practice. Though the cooling potion obtained by boiling such barley in water, and afterwards sweetening the liquor with liquorice root, is what at present goes by the name of ptisan; and to render it laxative, some add a little sena or other ingredient of the same intention.

**PTOLEMAIC SYSTEM OF ASTRONOMY**, is that invented by Claudius Ptolemaeus. See **PTOLEMY** (Claudius).

**PTOLEMAIS**, (anc. geog.) the port of Arsinoe, situated on the west branch of the Nile, which concurs to form the island called Nomos Heracleotes, to the south of the vertex of the Delta.

**PTOLEMAIS** (Strabo), the largest and most considerable town of Thebais or Higher Egypt, and in nothing short of Memphis; governed in the manner of a Greek republic; situated on the west side of the Nile, almost opposite to Coptos. This town, which was built by Ptolemy Philadelphus, is now known by the name of Ptolemeta. The walls and gates are still entire, and there are a vast number of Greek inscriptions, but only a few columns of the portico remain. There is likewise an Ionic temple, done in the most ancient manner of executing that order, of which Mr. Bruce took a drawing, which is preserved in the king's collection. Another of Cyrenaica, anciently called Barce.—A third of

the Troglodytica, surnamed Epitheras, from the chase of wild beasts, as elephants: lying in the same parallel with Meroë (Strabo); on the Arabian gulf (Pliny); 4820 stadia to the south of Berenice.—A fourth of Galilee, anciently called Aca, or Acon; made a Roman colony under the emperor Claudius (Pliny).—A fifth of Pamphilia; situated near the river Melas, on the borders of Cilicia Aspera.

**PTOLEMY**. This name was common to 13 kings of Egypt, to enter into a minute detail of whose history would exceed the bounds allotted to this repository. They succeeded in the following order: Ptolemy the 1st, surnamed Lagus, was son of Arsinoe, who, when pregnant by Philip of Macedonia, married Lagus, a man of mean extraction. (See **LAGUS**.) Being educated in the court of Macedonia, he became one of the friends of Alexander, and attended him as one of his generals. During the Asiatic expedition he behaved with uncommon valour. After the conqueror's death, Ptolemy obtained the government of Egypt with Libya and part of the neighbouring territories of Arabia. In this appointment he gained the esteem of the people by his benevolence and clemency. Though much engaged in military operations, he, however, was not forgetful of literature. In order that his subjects might be acquainted with literature, he laid the foundation of a library, which, under the succeeding reigns, became the most celebrated in the world. Ptolemy died in the 84th year of his age, after a reign of 39 years, about 284 years before Christ. He was called Soter, from his giving assistance to the Rhodians against Demetrius and Antigonus, and all his successors were called Ptolemies from him.—The 2d, son of Ptolemy the first, succeeded his father upon the Egyptian throne, and was called Philadelphus, by Antiphrasis, because he killed two of his brothers. He shewed himself worthy in every respect to succeed his great father, and died in the 64th year of his age, 246 years before the Christian era. He left two sons and a daughter, by Arsinoe, the daughter of Lysimachus. During the whole of his reign Philadelphus was employed in exciting industry, and in encouraging the liberal arts and useful knowledge among his subjects. His palace was the asylum of learned men, whom he admired and patronized. It is said that the Old Testament was translated into Greek during his reign, a translation which has been called Septuagint, because translated by the labours of 70 different persons.—The 3d, succeeded his father Philadelphus on the Egyptian throne. The Egyptians called him Evergetes, for his beneficence and religious zeal in rescuing above 23,000 statues of the Egyptian gods carried off into Persia by Cambyzes, when he conquered Egypt. Evergetes died 221 years before Christ, after a reign of 25 years, and, like his two illustrious predecessors, he was a liberal patron of learning. It is said that he deposited 15 talents in the hands of the Athenians to be permitted to translate the original manuscripts of Æschylus, Euripides, and Sophocles.—The 4th, succeeded his father Ever-

getes on the throne of Egypt, and received the surname of Philopater by Antiphrasis, because, according to some historians, he destroyed his father by poison. He began his reign with acts of the greatest cruelty, and sacrificed to his avarice his own mother, his wife, his sister, and his brother. He received the name of Tiphon, from his extravagance and debauchery, and that of Gallus, because he appeared in the streets of Alexandria like one of the bacchanals, and with all the gestures of the priests of Cybele. He was remarkably hostile to the Jewish nation, whom he attempted to extirpate. At length being weakened and enervated by intemperance and continual debauchery, Philopater died in the 37th year of his age, after a reign of 17 years, 204 years before the Christian era.—The 5th, succeeded his father Philopater as king of Egypt, though only in the fourth year of his age. During the years of his minority he was under the protection of Sosicius and of Aristomenes. When Ptolemy reached his 14th year, according to the laws and customs of Egypt, the years of his minority expired, and he ascended the throne. He received the surname of Epiphanes, or Illustrious, and was crowned at Alexandria with the greatest solemnity. He soon, however, betrayed the same vices which had characterized his father, and his cruelties raised seditions among his subjects. After a reign of 24 years, 180 years before Christ, Ptolemy was poisoned by his ministers, whom he had threatened to rob of their possessions to carry on a war against Seleucus king of Syria.—The 6th, succeeded his father Epiphanes on the Egyptian throne, and received the surname of Philometer by Antiphrasis, on account of his hatred against his mother Cleopatra. He was in the sixth year of his age when he ascended the throne, and during his minority the kingdom was governed by his mother, and at her death by an eunuch, one of his favourites. He made war against Antiochus Epiphanes, and after several successes, he fell into the hands of his enemy. During the captivity of Philometer, the Egyptians raised to the throne his younger brother Ptolemy Physcon, also son of Epiphanes, but Antiochus turned his arms against the usurper, and restored Philometer. This artful behaviour of Antiochus was soon comprehended by Philometer; he recalled his brother Physcon, and made him partner on the throne, and concerted with him how to repel their common enemy. Philometer died 145 years before the Christian era, leaving Physcon master of Egypt, and all the dependent provinces. Philometer has been commended by some historians for his clemency and moderation.—The 7th Ptolemy, surnamed Physcon, on account of the prominence of his belly, ascended the throne of Egypt after the death of his brother Philometer, and as he had reigned for some time conjointly with him (see Ptolemy 6th.) his succession was approved, though the wife and the son of the deceased monarch had laid claims to the crown. However, it was at last agreed, that Physcon should marry the queen, and that her son should succeed on the throne at his

death. The nuptials were accordingly celebrated, but on that very day the tyrant murdered Cleopatra's son in her arms. He ordered himself to be called Evergetes, but the Alexandrians refused to do it, and stigmatized him with the appellation of Kakergetes, or evil-deer. A series of barbarity rendered him odious to his subjects, and having at length become without friends or support in Egypt, he fled to Cyprus, and Cleopatra, his divorced queen, ascended the throne. In his banishment Physcon levied an army, and soon after this he invaded Egypt, and obtained a victory over the forces of Cleopatra. This decisive blow restored Physcon to his throne, where he continued to reign for some time, hated by his subjects and feared by his enemies. He died at Alexandria in the 67th year of his age, after a reign of 29 years, about 116 years before Christ.—The 8th, surnamed Lathyrus, from an excrescence like a pea on the nose, succeeded his father Physcon as king of Egypt. He had no sooner ascended the throne, than his mother Cleopatra, who reigned conjointly with him, expelled him to Cyprus, and placed the crown on the head of his brother Ptolemy Alexander, her favourite son. Lathyrus, banished from Egypt, became king of Cyprus, where he continued to reign till the death of his brother Alexander restored him to his possessions. Lathyrus died 81 years before the Christian era, after a reign of thirty-five years since the death of his father Physcon, eleven of which he had passed with his mother Cleopatra, on the Egyptian throne, eighteen in Cyprus, and seven after his mother's death. He was succeeded by his only daughter Cleopatra, whom Alexander, the son of Ptolemy Alexander, by means of the dictator Sylla, soon after married and murdered.—The 9th, (See Alexander Ptolemy 1st.) For the 10th Ptolemy, (See Alexander Ptolemy 2d.) For the 11th, (See Alexander Ptolemy 3d.)—The 12th, the illegitimate son of Lathyrus, ascended the throne of Egypt at the death of Alexander 3d. He received the surname of Auletes, because he played skillfully on the flute. He was established in the succession by Cæsar the consul, who granted him the alliance of the Romans, after he had received the enormous sum of about 1,162,500l. sterling. Auletes, however, was obliged some time after to fly from his kingdom, and seek protection among the most powerful of his allies, and during his absence from Alexandria, his daughter Berenice made herself absolute, and established herself on the throne, but she was soon driven from Egypt, when Gabinius, at the head of a Roman army, approached to replace Auletes on his throne. He was no sooner restored than he sacrificed to his ambition his daughter Berenice. Auletes died four years after his restoration, about 51 years before the Christian era.—The 13th, surnamed Dionysius or Bacchus, ascended the throne of Egypt conjointly with his sister Cleopatra, whom he had married, according to the directions of his father Auletes. He was under the care and protection of Pompey the Great, but the wickedness and avarice of his ministers

soon obliged him to drive away his sister from the throne, and to reign independent. He was then in the 13th year of his age when his guardian, after the fatal battle of Pharsalia, came to the shores of Egypt, and claimed his protection. He refused to grant the required assistance, and basely murdered Pompey after he had brought him to shore under the mask of friendship. Cæsar, who pursued Pompey to Egypt, became the arbiter on the succession of the throne of that kingdom, and having arrived at Alexandria, he found the king of Egypt as faithless to his cause as to that of his fallen enemy; he ordered the will of Auletes to be read, and he confirmed Ptolemy and Cleopatra in the possession of Egypt. This decision did not please Ptolemy, who thereupon refused to acknowledge Cæsar a mediator. The Roman enforced his authority by arms, and three victories were obtained over the Egyptian forces. Ptolemy, who had been for some time a prisoner in the hands of Cæsar, now headed his armies, but a defeat was fatal, and as he attempted to save his life by flight, he was drowned in the Nile, about 46 years before Christ, and three years and eight months after the death of Auletes. Cleopatra, at the death of her brother, became sole mistress of Egypt, but, as the Egyptians were no friends to female government, Cæsar obliged her to marry her younger brother Ptolemy, who was then in the eleventh year of his age.

PTOLEMY, or PTOLOMY (Claudius), a very celebrated geographer, astronomer, and mathematician, among the ancients, was born at Pelusium in Egypt, about the 70th year of the Christian era; and died, it has been said, in the 78th year of his age, and in the year of Christ 147. He taught astronomy at Alexandria in Egypt, where he made many astronomical observations, and composed his other works. It is certain that he flourished in the reigns of Marcus Antoninus and Adrian: for it is noted in his Canon, that Antoninus Pius reigned 23 years, which shews that he himself survived him; he also tells us in one place, that he made a great many observations upon the fixed stars at Alexandria, in the second year of Antoninus Pius; and in another, that he observed an eclipse of the moon, in the ninth year of Adrian; from which it is reasonable to conclude that this astronomer's observations upon the heavens were many of them made between the year 125 and 140.

Ptolemy has always been reckoned the prince of astronomers among the ancients, and in his works has left an entire body of that science. He has preserved and transmitted to us the observations and principal discoveries of the ancients, and at the same time augmented and enriched them with his own. He corrected Hipparchus's catalogue of the fixed stars; and formed tables, by which the motions of the sun, moon, and planets might be calculated and regulated. He was indeed the first who collected the scattered and detached observations of the ancients, and digested them into a system; which he sets forth in his *Μεγαλή Συναξίς*, sive

Magna Constructio, divided into 13 books. He adopts and exhibits here the ancient system of the world, which placed the earth in the centre of the universe; and this has been called from him the Ptolemaic System, to distinguish it from those of Copernicus and Tycho Brahe.

About the year 827 this work was translated by the Arabians into their language, in which it was called *Almagestum*, by order of one of their kings; and from Arabic into Latin, about 1230, by the encouragement of the emperor Frederic the 2d. There were also other versions from the Arabic into Latin; and a manuscript of one, done by Girardus Cremonensis, who flourished about the middle of the 14th century, Fabricius says, is still extant in the library of All Souls College in Oxford. The Greek text of this work began to be read in Europe in the 15th century; and was first published by Simon Grynæus at Basil, 1538, in folio, with the eleven books of commentaries by Theon, who flourished at Alexandria in the reign of the elder Theodosius. In 1541 it was reprinted at Basil, with a Latin version by George Trapezond; and again at the same place in 1551, with the addition of other works of Ptolemy, and Latin versions by Camerarius. We learn from Kepler, that this last edition was used by Tycho.

Of this principal work of the ancient astronomers it may not be improper to give here a more particular account. In general, it may be observed, that the work is founded upon the hypothesis of the earth's being at rest in the centre of the universe, and that the heavenly bodies, the stars and planets, all move round it in solid orbs, whose motions are all directed by one, which Ptolemy called the *Primum Mobile*, or first mover, of which he discourses at large. But, to be more particular, this great work is divided into 13 books.

In the first book, Ptolemy shews, that the earth is in the centre of those orbs, and of the universe itself, as he understood it: he represents the earth as of a spherical figure, and but as a point in comparison of the rest of the heavenly bodies: he treats concerning the several circles of the earth, and their distances from the equator; as also of the right and oblique ascension of the heavenly bodies in a right sphere.

In the 2d book, he treats of the habitable parts of the earth; of the elevation of the pole in an oblique sphere and the various angles which the several circles make with the horizon, according to the different latitude of places; also of the phenomena of the heavenly bodies depending on the same.

In the 3d book he treats of the quantity of the year, and of the unequal motion of the sun through the zodiac: he here gives the method of computing the mean motion of the sun, with tables of the same; and likewise treats of the inequality of days and nights.

In the 4th book, he treats of the lunar motions, and their various phenomena: he gives tables for finding the moon's mean motions, with her latitude and longitude: he discourses

largely concerning lunar epicycles; and by comparing the times of a great number of eclipses, mentioned by Hipparchus, Calippus, and others, he has computed the place of the sun and moon, according to their mean motions, from the first year of Nabonazar, king of Egypt, to his own time.

In the 5th book, he treats of the instrument called the Astrolabe: he treats also of the eccentricity of the lunar orbit, and the inequality of the moon's motion, according to her distance from the sun: he also gives tables and an universal canon for the inequality of the lunar motions: he then treats of the different aspects or phases of the moon, and gives a computation of the diameter of the sun and moon, with the magnitude of the sun, moon, and earth compared together; he states also the different measures of the distance of the sun and moon, according as they are determined by ancient mathematicians and philosophers.

In the 6th book, he treats of the conjunctions and oppositions of the sun and moon, with tables for computing the mean time when they happen; of the boundaries of solar and lunar eclipses; of the tables and methods of computing the eclipses of the sun and moon, with many other particulars.

In the 7th book, he treats of the fixed stars; and shews the methods of describing them, in their various constellations, on the surface of an artificial sphere or globe: he rectifies the places of the stars to his own time, and shews how different those places were then from what they had been in the times of Timocharis, Hipparchus, Aristillus, Calippus, and others: he then lays down a catalogue of the stars in each of the northern constellations, with their latitude, longitude, and magnitudes.

In the 8th book, he gives a like catalogue of the stars in the constellations of the southern hemisphere, and in the 12 signs or constellations of the zodiac. This is the first catalogue of the stars now extant, and forms the most valuable part of Ptolemy's works. He then treats of the galaxy, or milky-way; also of the planetary aspects, with the rising and setting of the sun, moon, and stars.

In the 9th book, he treats of the order of the sun, moon, and planets, with the periodical revolutions of the five planets; then he gives tables of the mean motions, beginning with the theory of Mercury, and shewing its various phenomena with respect to the earth.

The 10th book begins with the theory of the planet Venus, treating of its greatest distance from the sun; of its epicycle, eccentricity, and periodical motions: it then treats of the same particulars in the planet Mars.

The 11th book treats of the same circumstances in the theory of the planets Jupiter and Saturn. It also corrects all the planetary motions from observations made from the time of Nabonazar to his own.

The 12th book treats of the retrogressive motion of the several planets; giving also tables of their stations, and of the greatest distances of Venus and Mercury from the sun.

The 13th book treats of the several hypotheses of the latitude of the five planets; of the greatest latitude, or inclination of the orbits of the five planets, which are computed and disposed in tables; of the rising and setting of the planets, with tables of them. Then follows a conclusion or winding up of the whole work.

This great work of Ptolemy will always be valuable on account of the observations he gives of the places of the stars and planets in former times, and according to ancient philosophers and astronomers that were then extant; but principally on account of the large and curious catalogue of the stars, which being compared with their places at present, we thence deduce the true quantity of their slow progressive motion according to the order of the signs, or of the precession of the equinoxes.

Another great and important work of Ptolemy was, his Geography, in 7 books; in which, with his usual sagacity, he searches out and marks the situation of places according to their latitudes and longitudes; and he was the first that did so. Though this work must needs fall far short of perfection, through the want of necessary observations, yet it is of considerable merit, and has been very useful to modern geographers. Cellarius indeed suspects, and he was a very competent judge, that Ptolemy did not use all the care and application which the nature of his work required; and his reason is, that the author delivers himself with the same fluency and appearance of certainty, concerning things and places at the remotest distance, which it was impossible he could know any thing of, that he does concerning those which lay the nearest to him, and fall the most under his cognizance. Salmasius had before made some remarks to the same purpose upon this work of Ptolemy. The Greek text of this work was first published by itself at Basil in 1533, in 4to: afterwards with a Latin version and notes by Gerard Mercator, at Amsterdam, 1605; which last edition was reprinted at the same place, 1618, in folio, with neat geographical tables, by Bertius.

Other works of Ptolemy, though less considerable than these two, are still extant. As, *Libri quatuor de Judiciis Astrorum*, upon the first two books of which Cardan wrote a commentary.—*Fructus Librorum suorum*; a kind of supplement to the former work.—*Recensio Chronologica Regum*: this, with another work of Ptolemy, *De Hypothesibus Planetarum*, was published in 1620, 4to, by John Bainbridge, the Savilian professor of astronomy at Oxford: and Scaliger, Petavius, Dodwell, and the other chronological writers, have made great use of it.—*Apparentiæ Stellarum Inerrantium*: this was published at Paris by Petavius, with a Latin version, 1630, in folio; but from a mutilated copy, the defects of which have since been supplied from a perfect one, which sir Henry Saville had communicated to archbishop Usher, by Fabricius, in the 3d volume of his *Bibliotheca Græca*.—*Elementorum Harmonicorum libri tres*; published in Greek and Latin, with

a commentary by Porphyry the philosopher, by Dr. Wallis at Oxford, 1682, in 4to; and afterwards reprinted there, and inserted in the 3d volume of Wallis's works, 1699, in folio. (*Hutton's Dict.*).

**PTOSIS.** (πτωσις, from πτείνω, to fall.) In medicine, a synonym of blepharoptosis. See BLEPHAROPTOSIS.

**PTOSIS IRIDIS.** Prolapsus iridis, is a prolapsus of the iris through a wound of the cornea. It is known by a blackish tubercle, which prominates a little from the cornea in various forms. The species of the ptosis of the iris are, 1. Ptosius recens, or a recent ptosis from a side wound of the cornea, as that which happens, though rarely, in or after the extraction of the cataract. 2. Ptosius inveterata, in which the incarcerated prolapsed iris is grown or attached to the wound or ulcer, and by the air has become callous or indurated.

**PTYALISM.** (πτυαλισμος, from πτυαλιζω, to spit.) A salivation, or increased secretion of saliva from the mouth.

**PTYSMAGOGUE.** s. (πτυσμα and αγω.) A medicine which discharges spittle.

**PUBERTY.** s. (*pulertas*, Latin.) The time of life in which the two sexes begin first to be acquainted (*Bentley*).

**PUBES.** (from βουβων, the groin.) The external part of the organs of generation of both sexes, which is covered with hair.

**PUBES.** In botany. Pubescence. Hirsuties omnis in planta. Delin. Pl.—vestiens villositate. All hairiness, or shagginess in a plant; or whatever clothes it with any hairy or villous substance. Linnéus's original word was pubescentia, and he explained it to mean the armour of a plant, by which it is defended from external injuries: thus comprehending thorns and prickles under the idea of pubescence. These however he afterwards separated, and called them with more propriety arma. The following are the different forms of pubescence:

1. Pili. Hairs. Excretory ducts, in that form.

2. Lana. Wool; or close curled hairs.

3. Barba. Beard; or parallel hairs.

4. Tomentum. Flocks; or interwoven villous hairs scarcely conspicuous.

5. Strigæ. Stiffish flattish hairs.

6. Setæ. Bristles. Stiffish roundish hairs.

7. Hami. Hooks. Sharp crooked points.

8. Glochides. Barbs. Straight toothed points.

9. Glandulæ. Glands. Small papillæ or teats, or excretory ducts in that form.

Yet glands seem to be improperly enumerated as a species of pubescence.

**PUBESCENCE.** s. (from *pubesco*, Latin.) The state of arriving at puberty (*Brown*).

**PUBESCENT.** a. (*pubescens*, Lat.) Arriving at puberty (*Brown*).

**PUBIS** (Os). A bone of the fetal pelvis. See INNOMINATUM OS.

**PUBLIC.** a. (*publique*, Fr. *publicus*, Lat.)

1. Belonging to a state or nation; not private (*Hooker*). 2. Open; notorious; generally known (*Mat.*). 3. General; done by many

(*Milton*). 4. Regarding not private interest, but the good of the community (*Clarendon*).

5. Open for general entertainment (*Addison*).

**PUBLIC.** s. (from *publicus*, Latin.) 1. The general body of mankind, or of a state or nation; the people (*Addison*). 2. Open view; general notice (*Locke*).

**PUBLICAN.** s. (from *publicus*, Latin.) 1. A toll-gatherer (*Matthew*). 2. A man that keeps a house of general entertainment.

**PUBLICATION.** s. (from *publico*, Lat.) 1. The act of publishing; the act of notifying to the world; divulgation (*Hooker*). 2. Edition; the act of giving a book to the public (*Pope*).

**PUBLICLY.** ad. (from *public*.) 1. In the name of the community (*Addison*). 2. Openly; without concealment (*Bacon*).

**PUBLICNESS.** s. (from *public*.) 1. State of belonging to the community (*Boyle*). 2. Openness; state of being generally known or public.

**PUBLICSPIRITED.** a. (*public* and *spirit*.) Having regard to the general advantage above private good (*Dryden*).

**To PUBLISH.** v. a. (*publier*, French.) 1. To discover to mankind; to make generally and openly known (*Milton*). 2. To put forth a book into the world (*Digby*).

**PUBLISHER.** s. (from *publish*.) 1. One who makes public or generally known (*Atterbury*). 2. One who puts out a book into the world (*Prior*).

**PUBLIUS SYRUS**, a Syrian mimic poet, who flourished about 44 years B.C. He was originally a slave sold to Domitius, who brought him up with great attention, and gave him his freedom. He gained the esteem of the most powerful at Rome, and reckoned J. Cæsar among his patrons. There remains of Publius a collection of moral sentences, written in iambics.—2. Publius, was a prænomen, very common among the Romans.—3. A prætor who conquered Palæopolis. He was only a plebeian, and though neither consul nor dictator, he obtained a triumph in spite of the opposition of the senators. He was the first who was honoured with a triumph during a prætorship.

**PUCCINIA**, in botany, a genus of the class cryptogamia, order fungi. Fungus cylindrical, filled with tailed seeds, radiately disposed, and escaping elastically. Two species; exotics.

**PUCELAGE.** s. (French.) A state of virginity.

**PUCCOON**, in botany. See SANGUINARIA.

**PUCERON**, in entomology. See APHIS.

**PUCK.** s. (perhaps the same with *pug*.) Some sprite among the fairies, common in romances (*Corbet*).

**PUCKBALL**, or **PUCKFIET.** s. (from *puck*, a fairy's ball.) A kind of mushroom full of dust.

**To PUCKER.** v. a. (from *puck* the fairy.) To gather into corrugations; to contract into folds or plications (*Spectator*).

**PUCKHOLI**, a town of Hindustan Pro-

per in the province of Lahore, 86 miles S.W. of Cashmere, and 145 N.W. of Lahore. Lon. 72. 5 E. Lat. 33. 45 N.

**PUDDAR**, a river of Hindustan Proper, which rises in the S.W. part of Agimere, divides the provinces of Cutch and Guzerat, and falls into the gulph of Cutch.

**PUDDER**. *s.* (*fudur*, Islandic, a rapid motion.) A tumult; a turbulent and irregular bustle. Commonly written *potter* (*Locke*).

To **PU'DDER**. *v. n.* (from the noun.) To make a tumult; to make a bustle (*Locke*).

To **PU'DDER**. *v. a.* To perplex; to disturb; to confound (*Locke*).

**PUDDING**. *s.* (*puding*, Swedish.) 1. A kind of food very variously compounded, but generally made of meal, milk, and eggs. 2. The gut of an animal (*Shakspeare*). 3. A bowel stuffed with certain mixtures of meal and other ingredients. 4. A proverbial name for victuals (*Prior*).

**PUDDING GRASS**. See **MENTHA PULEGIUM**.

**PUDDING-PIPE GRASS**. See **CASSIA**.

**PUDDING-FISH**, in ichthyology. See **SPARUS**.

**PUDDING-WEED**. See **ALCYONIUM**.

**PUDDING-STONE**. See **BRECCIA**.

**PU'DDINGPIE**. *s.* (*pudding and pie*.) A pudding with meat baked in it (*Hudibras*).

**PU'DDINGTIME**. *s.* (*pudding and time*.) 1. The time of dinner; the time at which pudding, anciently the first dish, is set upon the table. 2. Nick of time; critical minute (*Hudibras*).

**PU'DDLE**. *s.* (from *puteolus*, Lat. *Skinner*.)

A small muddy lake; a dirty plash (*Hall*).

To **PU'DDLE**. *v. a.* (from the noun.) To muddy; to foul or pollute with dirt; to mix dirt and water (*Sidney*).

**PU'DDLY**. *a.* (from *puddle*.) Muddy; dirty; miry (*Carew*).

**PU'DDOCK**, or **PURROCK**. *s.* (for *paddock* or *parrock*.) A provincial word for a small enclosure.

**PU'DENCY**. *s.* (*pudens*, Latin.) Modesty; shamefacedness (*Shakspeare*).

**PUDENDA**. (from *pudor*, shame.) The parts of generation.

**PUDICAL ARTERY**. *Arteria pudica*. Pudendal artery. A branch of the internal iliac distributed on the organs of generation.

**PUDICITY**. *s.* (*pudicité*, French; from *pudicitia*, Latin.) Modesty; chastity.

**PUDOGA**, a town of Russia, in the government of Olonetz; situate on the E. coast of the lake Onezkoë, 108 miles E. of Olonetz. Lon. 36. 30 E. Lat. 61. 36 N.

**PUEBLA**, a town of Spain, in Galicia, near the Atlantic, 25 miles S.S.W. of Compostella. Lon. 8. 7 W. Lat. 42. 34 N.

**PUEBLA**, a town of Spain, in Estremadura, seated near the Guadiana, 15 miles W. of Merida. Lon. 6. 23 W. Lat. 38. 42 N.

**PUEBLA-DE-LOS-ANGELOS**, a town of New Spain, in the audience of Mexico, and province of Tlascala, of which it is the capital,

with a bishop's see. It is 62 miles S.E. of Mexico.

**PUEBLA-NUOVA**, a seaport of New Spain, in the audience of Guatemala, and province of Veragua. It is seated on a bay of the Pacific Ocean, 200 miles W. of Panama. Lon. 83. 28 W. Lat. 8. 48 N.

**PUNTE-DEL-ARCOBISPO**, a town of Spain, in Estremadura, which belongs to the archbishop of Toledo, and is seated on the river Tajo, over which is a handsome bridge, 40 miles S.W. of Toledo. Lon. 4. 15 W. Lat. 39. 38 N.

**PUNTE-DE-LA-REYNE**, a town of Spain, in Navarre, seated on the river Agra, 10 miles S.W. of Pampeluna. Lon. 1. 39 W. Lat. 42. 41 N.

**PU'ERILE**. *a.* (*puerile*, Fr. *puerilis*, Lat.) Childish; boyish (*Pope*).

**PUERI'LITY**. *s.* (*puerilitas*, Lat.) Childishness; boyishness (*Dryden*).

**PUERPERAL FEVER**. Childbed fever. Cullen considers this disease as a species of continued fever.

**PUERTO BELLO**, **PUERTO RICO**, &c. For all names, which, in the Spanish language, signify a port, see **PORTO**; for, although that word is not Spanish, but Italian, it is better to adhere to it in this work, in conformity to the English pronunciation.

**PUFF**. *s.* (*pos*, Dutch.) 1. A quick blast with the mouth (*Philips*). 2. A small blast of wind (*Raleigh*). 3. A fungous ball filled with dust. 4. Any thing light and porous; as, *puff* paste. 5. Something to sprinkle powder on the hair.

To **PUFF**. *v. n.* (*boffen*, Dutch.) 1. To swell the cheeks with wind. 2. To blow with a quick blast (*Shaks.*). 3. To blow with scornfulness (*South*). 4. To breathe thick and hard (*L'Estrange*). 5. To do or move with hurry, tumour, or tumultuous agitation (*Herbert*). 6. To swell with the wind or air (*Boyle*).

To **PUFF**. *v. a.* 1. To swell as with wind (*Ray*). 2. To drive or agitate with blasts of wind (*Shaks.*). 3. To drive with a blast of breath scornfully (*Dryden*). 4. To swell or blow up with praise (*Bacon*). 5. To swell or elate with pride (*Shakspeare*).

**PUFFBALL**. See **LYCOPERDON**.

**PUFFENDORF** (Samuel de), was born in 1631, at Fleh, a little village in Misnia, a province in Upper Saxony; and was son of Elias Puffendorf, minister of that place. After having made great progress in the sciences at Leipzig, he turned his thoughts to the study of the public law, which in Germany consists of the knowledge of the rights of the empire over the princes and states of which it is composed, and those of the princes and states with respect to each other. But though he used his utmost efforts to distinguish himself, he despised the various titles which are so much sought for at universities, and never would take the degree of doctor. He accepted the place of governor to the son of Mr. Coyet, a Swedish nobleman who was then ambassador from Sweden to the

court of Denmark. For this purpose he went to Copenhagen, but continued not long at ease there; for the war being renewed some time after between Denmark and Sweden, he was seized with the whole family of the ambassador. During his confinement, which lasted eight months, as he had no books, and was allowed to see no person, he amused himself by meditating on what he read in Grotius's treatise *De Jure Belli et Pacis*, and the political writings of Mr. Hobbes. Out of these he drew up a short system, to which he added some thoughts of his own, and published it at the Hague in 1660, under the title of *Elementa Jurisprudentiæ Universalis*. This recommended him to the elector Palatine, who invited him to the university of Heidelberg, where he founded in his favour a professorship of the law of nature and nations, which was the first of that kind established in Germany. Puffendorf remained at Heidelberg till 1673, when Charles XI. of Sweden gave him an invitation to be professor of the law of nature and nations at Lund; which place the elector Palatine reluctantly allowed him to accept. He went thither the same year; and after that time his reputation greatly increased. Some years after the king of Sweden sent for him to Stockholm, and made him his historiographer, and one of his counsellors. In 1688, the elector of Brandenburg obtained the consent of his Swedish majesty, that he should come to Berlin, in order to write the history of the elector William the Great; and in 1694 made him a baron. But he died that same year of an inflammation in his feet, occasioned by cutting his nails; having attained his grand climacteric. Of his works, which are numerous, the following are the principal: 1. A Treatise on the Law of Nature and Nations, written in German; of which there is an English translation with Barbeyrac's notes. 2. An Introduction to the History of the Principal States which at present subsist in Europe; written in German; which has been also translated into English. 3. The History of Sweden from Gustavus Adolphus's Expedition into Germany to the Abdication of Queen Christina. 4. The History of Charles Gustavus, two volumes folio, &c.

**PUFFER.** *s.* (from *puff*.) One that puffs.

**PUFFIN.** *s.* (*puffino*, Italian.) In ornithology. See **ALCA**.

**PUFFINGLY.** *ad.* (from *puffing*.) 1. Tumidly; with swell. 2. With shortness of breath.

**PUFFY.** *a.* (from *puff*.) 1. Windy; flatulent (*Wiseman*). 2. Tumid; turgid (*Dryden*).

**PUG.** *s.* (*piza*, Saxon.) A kind name of a monkey or any thing tenderly loved (*Adison*).

**PUGET** (Peter Paul), one of the greatest painters and sculptors France ever produced, though but little noticed by their own writers, was born at Marseilles in 1623. In his youth he was the disciple of Roman, an able sculptor; and then went to Italy, where he studied

painting and architecture. In painting he so well imitated the manner of Peter de Cortona, that this painter desired to see him, and entered into a friendship with him. In 1657, a dangerous disorder obliged him to renounce the pencil, and devote himself to sculpture; and his reputation causing him to be invited to Paris, he enjoyed a pension of 1200 crowns as sculptor and director of the works relating to vessels and galleys. He died at Marseilles in 1695, and has left a number of admirable statues behind him both in France and Italy.

**PUGGERED.** *a.* (perhaps for *puckered*.) Crowded; complicated (*More*).

**PUGH.** *interj.* A word of contempt.

**PUGIL.** *s.* (*pugille*, French.) What is taken up between the thumb and first two fingers (*Bacon*).

**PUGIONUM**, in botany, a genus of the class tetradynamia, order siliculosæ. Silicle transversely oval, terminated on each side by a horn, without valves, two-seeded; seed coated. One species; a native of Siberia.

**PUGLIA**, the modern name of the ancient Apulia, containing the three provinces of Capitanata, Bari, and Otranto, on the E. side of the kingdom of Naples.

**PUGNACIOUS.** *a.* (*pugnax*, Latin.) Inclined to fight; quarrelsome; fighting.

**PUGNACITY.** *s.* (from *pugnax*, Latin.) Quarrelsome; inclination to fight.

**PUISNE.** *a.* (*puis nê*, French.) 1. Young; younger; later in time (*Hale*). 2. Inferiour; lower in rank (*Bacon*). 3. Petty; inconsiderable; small (*Shakspeare*).

**PUISSANCE.** *s.* (*puissance*, Fr.) Power; strength; force (*Milton*).

**PUISSANT.** *a.* (*puissant*, French.) Powerful; strong; forcible (*Raleigh*).

**PUISSANTLY.** *ad.* Powerfully; forcibly.

**PUKE.** *s.* (of uncertain derivation.) 1. Vomit. 2. Medicine causing vomit.

**To PUKE.** *v. n.* To spew; to vomit (*Shakspeare*).

**PUKER.** *s.* (from *puke*.) A medicine causing vomit (*Garth*).

**PULAON**, an island in the Indian Ocean, lying on the W. of the Philippines. It is very fertile, and subject to its own king, who is tributary to that of Borneo. Lon. 129. 12 E. Lat. 9. 30 N.

**PULCHERIA.** The most remarkable of this name is—A daughter of Arcadius, who held the government of the Roman empire for many years. She was mother of Valentinian. Her piety, and her private as well as public virtues, have been universally admired. She died A. D. 452, and was interred at Ravenna, where her tomb is still to be seen.

**PULCHRITUDE.** *s.* (*pulchritudo*, Latin.) Beauty; grace; handsomeness (*More*).

**To PULE.** *v. n.* (*piauler*, French.) 1. To cry like a chicken (*Bacon*). 2. To whine; to cry; to whimper (*Locke*).

**PULEGIUM.** (from *pulex*, a flea; because the smell of its leaves burnt destroys fleas.) Pennyroyal. *Mentha pulegium* of Linnæus.

*Mentha floribus verticillatis, foliis ovatis obtusis suberenatis, caulibus subteretibus repentibus.* C. O. Didynamia, Gymnospermia. This plant is considered as a carminative, stomachic, and emmenagogue; and is in very common use in hysterical disorders. The official preparations of pennyroyal are, a simple water, a spirit, and an essential oil.

**PULEGIUM CERVINUM.** Hart's pennyroyal. *Mentha cervina* of Linnéus. This plant possesses the virtues of pennyroyal in a very great degree; but is remarkably unpleasant. It is seldom employed but by the country people, who substitute it for pennyroyal.

**PULEX.** Flea. In zoology, a genus of the class insecta, order aptera. Mouth without jaws or feelers, with a long inflected proboscis, covered at the base with two ovate laminæ, the sheath two-valved, five-jointed, and concealing a single bristle; lip rounded and fringed with reflected prickles; antennæ projecting, moniliform; eyes two; abdomen compressed; legs six, formed for leaping. Two species. 1. *P. irritans.* Bed-flea. Proboscis shorter than the body. This insect is said to prefer the more delicate skin of women; and to feed neither upon epileptic persons, upon the dead, nor the dying. Other animals, as well as man, suffer by its intrusions. It nestles in the fur of dogs, cats, and rats; and the nests of the river swallow swarm with them. The antennæ are longer than the thorax; body of a dark brown colour, and of an oval form; walks but little; but by the elasticity of its legs, can spring above two hundred times the length of its own body. From microscopic observations which have been made upon this animal, it has been found to be oviparous. The eggs are deposited on blankets, or among the down of animals; they are round and smooth; and in four or five days give birth to a very minute larvæ, which feeds upon greasy fur. After having crept about for a few days, the larvæ spins a silken cod, in which it lies dormant for about a fortnight in its pupæ state; after which it bursts from its confinement, endowed with powers to disturb the peace of quadrupeds and of man.

Preparations of mercury are effectual in destroying the flea, and most other noxious vermin. In some places bugs, fleas, and other abominable insects, are held in superstitious veneration. At Surat, there is an hospital endowed for their preservation; where every night some poor wretch suffers himself to be preyed upon for their sustenance. They fasten him naked upon a bed, where he is deprived of the means of self-defence; and the famished pensioners riot in his blood during the whole night. Another foundation of a similar nature, but less ludicrous, is erected in Turkey, for decayed or infirm dogs.

2. *P. penetrans.* Chigoe, or chigger. Proboscis as long as the body; body reddish-brown; abdomen of the female when gravid, orbicular and swollen to nearly a hundred times its usual size. Inhabits South America, and is very troublesome in the sugar-colonies, penetrating the skin of the inhabitants, where it lodges its

eggs, and causes malignant and often fatal ulcers.

In proof of the great strength and agility of the common flea (*P. irritans*), we quote the following account from Martin's *Miscellaneous Correspondence*, vol. iii. p. 75. "Mr. Boverick, a watch-maker in the Strand, lately made and shewed to vast numbers of people, not only a chaise having four wheels and all its proper apparatus, together with a man sitting thereon; the whole formed with ivory, and drawn along by a flea;—but likewise a landau, which opens and shuts by springs, with six horses harnessed thereto, a coachman sitting on the box, and a dog between his legs; four people in the landau, two footmen behind it, and a postilion riding one of the fore-horses. This equipage a flea is fastened to, and draws very easily along.

Mr. B. has also made a chain of brass, about two inches long, containing 200 links, with a hook at one end, and a padlock and key at the other; all which together weigh less than a third part of the whole machine. Here too a flea is made use of to draw the chain, which it does very nimbly, and with as little trouble as can be imagined. "Of this curious spectacle we ourselves," says Martin, "made a part of the admiring multitude, who had the satisfaction to behold it."

**PULHELY**, a town of Wales, in Carnarvonshire, with a market on Wednesday, seated on an inlet of Cardigan bay, between two rivers, 16 miles S. of Carnarvon, and 243 N.W. of London.

**PULICARIA.** (from *pulex*, a flea; so named because it was thought to destroy fleas if hung in a chamber.) See **PSYLLIUM**.

**PULICASE.** *a. (pulicosus, Lat.)* Abounding with fleas.

**To PULL.** *v. a. (pullian, Saxon.)* 1. To draw violently toward one; opposed to *push*, which is to drive from one (*Ben Jonson*). 2. To draw forcibly (*Hayward*). 3. To pluck; to gather (*Mortimer*). 4. To tear; to rend (*Lamentations*). 5. **To PULL down.** To subvert; to demolish (*Howel*). 6. **To PULL down.** To degrade (*Roscom.*). 7. **To PULL up.** To extirpate; to eradicate (*Locke*).

**PULL. s. (from the verb.)** 1. The act of pulling (*Swift*). 2. Contest; struggle (*Carew*). 3. Pluck; violence suffered (*Shakspeare*).

**PULLER. s. (from pull.)** One that pulls (*Shakspeare*).

**PULLEN. s.** Poultry (*Bailey*).

**PULLET. s. (poulet, Fr.)** A young hen (*Brown*).

**PULLEY**, in mechanics, one of the mechanical powers; consisting of a little wheel, or rundle having a channel around it, and turning on an axis; serving, by means of a rope which slides in its channel, for the raising of weights.

The Latins call it *trochlea*; and the seamen, when fitted with a rope, a tackle. An assemblage of several pulleys is called a system of pulleys, or polyspaston: some of which are in a block or case, which is fixed; and others in a block which is moveable, and rises with the

## P U L L E Y.

weight. The moveable wheel or rundle, is called the sheave or shiver; the axis on which it turns, the gudgeon; and the fixed piece of wood or iron, into which it is put, the block.

*Doctrine of the Pulley.*—If the equal weights *W* and *P* (Pl. 145, fig. 2.) hang by the cord *BB* upon the pulley *A*, whose block *b* is fixed to the beam *HI*, they will counterpoise each other, just in the same manner as if the cord was cut in the middle, and its two ends hung upon the hooks fixed in the pulley at *A* and *A*, equally distant from its centre. Hence, a single pulley, if the lines of direction of the power and the weight be tangents to the periphery, neither assists nor impedes the power, but only changes its direction.

The use of the pulley, therefore, is when the vertical direction of a power is to be changed into an horizontal one; or an ascending direction into a descending one; and on the contrary.

This is found a good provision for the safety of the workmen employed in drawing with the pulley.

This change of direction by means of a pulley has this farther advantage; that if any power can exert more force in one direction than another, we are here able to employ it in its greatest force.

Thus, e. gr. a horse cannot draw in a vertical direction, but draws with all its advantage in a horizontal one. By changing the vertical draught, therefore, into a horizontal one, a horse becomes qualified to raise a weight.

But the grand use of the pulley is, where several of them are combined; thus forming what Vitruvius, and others after him, call polyspasta; the advantages whereof are, that the machine takes up but little room, is easily removed, and raises a very great weight with a moderate force.

If a weight *W* hangs at the lower end of the moveable block *p* of the pulley *D*, and the cord *GF* goes under the pulley, it is plain that the half *G* of the cord bears one half of the weight *W*, and the half *F* the other; for they bear the whole between them. Therefore, whatever holds the upper end of either rope, sustains one half of the weight; and if the cord at *F* be drawn up so as to raise the pulley *D* to *C*, the cord will then be extended to its whole length, except that part which goes under the pulley; and consequently the power that draws the cord will have moved twice as far as the pulley *D* with its weight *W* rises; on which account, a power whose intensity is equal to one half of the weight, will be able to support it, because if the power moves (by means of a small addition) its velocity will be double the velocity of the weight; as may be seen by putting the cord over the fixed pulley *C* (which only changes the direction of the power, without giving any advantage to it) and hanging on the weight *P*, which is equal only to one half of the weight *W*; in which case there will be an equilibrium, and a little addition to *P* will cause it to descend, and raise *W* through a space equal to one half of that through which *P* descends. Hence, the advantage gained will be always equal to twice the number of pulleys in

the moveable or undermost block. So that, when the upper or fixed block *u* contains two pulleys, which only turn on their axes, and the lower or moveable block *U* contains two pulleys, which not only turn upon their axes, but also rise with the block and weight, the advantage gained by this is as four to the working power. Thus, if one end of the rope *KMOQ* be fixed to a hook at *L*, and the rope passes over the pulleys *N* and *R*, and under the pulleys *L* and *P*, and has a weight *T* of one pound hung to its other end at *T*, this weight will balance and support a weight *W* of four pounds, hanging by a hook at the moveable block *U*, allowing the said block as a part of the weight. And if as much more power be added, as is sufficient to overcome the friction of the pulleys, the power will descend with four times as much velocity as the weight rises, and consequently through four times as much space. The two pulleys in the fixed block *X*, and the two in the moveable block *Y*, are in the same case with those last mentioned; and those in the lower block give the same advantage to the power.

Another very useful combination of pulleys is that in fig. 3, pl. 145, where a weight or force at *P* will balance another at *W* of sixteen times its magnitude. If a power move a weight by means of several pulleys, the space passed over by the power will be to the space passed over by the weight, as the weight to the power.

Hence, the smaller the force that sustains a weight by means of pulleys is, the slower is the weight raised: so that what is saved in force, is spent in time.

The common methods of arranging pulleys in their blocks may be reduced to two. The first consists in placing them one by the side of another, upon the same pin; the other, in placing them directly under one another, upon separate pins. Each of these methods is liable to inconvenience. Mr. Smeaton, in order to avoid the impediments to which these combinations are subject, proposes to combine these two methods in one. Accordingly, the pulleys are placed in each block in two tiers; several being upon the same pin, as in the first method, and every one having another under it, as in the second; and so that, when the tackle is in use, the two tiers that are the remotest from one another, are so much larger in diameter than those that are nearest, as to allow the lines of the former to go over the lines of the latter without rubbing. From this construction arises a new method of reeving the line upon the shieves; for here, whatever be the number of shieves, the fall of the tackle will be always upon the middle shieve, or on that next to the middle, according as the number of pulleys in each pin is odd or even. To do this, the line is fixed to some convenient part of the upper block, and brought round the middle shieve of the larger tier of the under block, from thence round one of the same sort next to the centre one of the upper block, and so on, till the line comes to the outside shieve, where the last line of the larger tier falls upon the first shieve of the smaller, and being reeved round

those, till it comes at the opposite side, the line from the last shieve of the smaller tier again rises to the first of the larger, whence it is conducted round, till it ends on the middle shieve of the upper block on the larger tier.

As a system of pulleys has no great weight, and lies in a small compass, it is easily carried about, and can be applied for raising weights in a great many cases, where other engines cannot be used. But they are subject to a great deal of friction, on the following accounts, viz. 1st, because the diameters of their axes bear a very considerable proportion to their own diameters; 2d, because in working they are apt to rub against one another, or against the sides of the block; 3dly, because of the stiffness of the rope that goes over and under them.

To PULLULATE. *v. n.* (*pullulo*, Latin; *pulluler*, French.) To germinate; to bud.

PULMONARIA. Lungwort. In botany, a genus of the class pentandria, order monogynia. Corol funnel-form with the throat pervious; calyx prismatic, five-sided. Seven species: natives of Europe and America; two of our own country. The three following are cultivated.

1. *P. officinalis*. Common or spotted lungwort. Jerusalem cowslips. Perennial, fibrous root; leaves rough-haired; those of the stem ovate oblong, radical ones a little heart-shaped. This plant is rarely found to grow wild in England; but is very commonly cultivated in gardens, where its leaves become broader, and approach more to a cordate shape. The leaves, which are the part medicinally used, have no peculiar smell; but, in their recent state, manifest a slightly astringent and mucilaginous taste; hence it seems not wholly without foundation that they have been supposed to be demulcent and pectoral. They have been recommended in hemoptoës, tickling coughs, and catarrhal defluents upon the lungs. The name *pulmonaria*, however, seems to have arisen rather from the speckled appearance of these leaves, resembling that of the lungs, than from any intrinsic quality which experience discovered to be useful in pulmonary complaints.

2. *P. angustifolia*. Narrow-leaved lungwort. Leaves much narrower than those of the first sort, covered with soft hair; flowers produced in small bunches at the top of the stalks. A native of Europe; flowers from March to May.

3. *P. Virginiana*. Virginian lungwort. Perennial, thick, fleshy root; sending out many small fibres; stalks a foot and half high, dividing at the top into several short branches; flowers blue, red and white, appearing in April. A native of North America.

These plants are propagated by seeds and parting the roots.

PULMONARY. PULMO'NIC. *a.* (from *pulmo*, Latin.) Belonging to the lungs (*Arbuthnot*).

PULMONARY VESSELS. The pulmonary artery, *arteria pulmonalis*, arises from the right ventricle of the heart, and soon divides into the right and left, which ramify throughout the lungs, and form a beautiful net-work on the

air vesicles, where they terminate in the veins, *venæ pulmonales*, whose branches at length form four trunks, which empty themselves into the left auricle of the heart.

PULP. *s.* (*pulpa*, Latin; *pulpe*, French.) 1. Any soft mass (*Bacon*). 2. The soft part of fruit (*Ray*).

PULPIT, an elevated place in a church, whence sermons are delivered. The French give the same name to a reading-desk.

PULPITUM, in the Grecian and Roman theatres, was a place where the players performed their parts. It was lower than the scena, and higher than the orchestra. It nearly answered to what we call the stage, as distinguished from the pit and galleries.—Pulpitum was also a moveable desk or pulpit, from which disputants pronounced their dissertations, and authors recited their works.

PULPOUS. *a.* (from *pulp.*) Soft (*Philips*).

PULPOUS LEAF. A pulpy leaf filled with a tenacious substance between the two surfaces.—Linnæus did not originally distinguish this from carnosous, which has a firmer pulp.

PULPOUSNESS. *s.* (from *pulpous*.) The quality of being pulposous.

PULPY. *a.* (from *pulp.*) Soft; pappy (*Arbuthnot*).

PULSATILLA NIGRICANS. (from *pulso*, to beat about; so called from its being perpetually agitated by the air.) This plant, *Anemone pratensis* of Linnæus, (*Anemone pedunculo involucreto*, petals apice reflexis, foliis bipinnatis; C. O. polyandria, polygynia,) has been received into the Edinburgh pharmacopœia upon the authority of baron Stœrck, who recommended it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amaurosis, cataract, and opacity of the cornea, proceeding from various causes. He likewise found it of great service in venereal nodes, nocturnal pains, ulcers, caries, indurated glands, suppressed menses, serpiginous eruptions, melancholy, and palsy. The plant, in its recent state, has scarcely any smell; but its taste is extremely acid, and, when chewed, it corrodes the tongue and fauces.

PULSATION, the beating or motion of the pulse. See PULSE.

PULSE. PULSUS. (from *pulso*, to beat.) That stroke which is felt on applying the finger to an artery in a living animal. This is occasioned by the reciprocal action of the heart and arteries, the blood being propelled from the left ventricle of the heart into the arteries, so as to be distributed through the whole machine, and in so perceptible a manner, that the distension of the arterial tube can be felt by the finger. But before the time of Hippocrates, the pulses were not attended to, and indeed very slightly by him, as there are only one or two places in which he makes mention of them, throughout the whole of his works. Herophilus was the first who considered the pulse with accuracy, and wrote elaborate treatises on it. In Celsus's time the pulse was very much attended to, and consulted, though he calls it res

fallacissima. Galen, however, wrote most voluminously and laboriously upon this subject, a very good epitome of which may be seen in Prosper Alpinus de Præsignenda Vita & Morte. Boerhaave, in his Institutes, gives an account of all the ancients knew concerning the pulse in a short compass, which is well explained by his commentator, Haller. Long experience, however, has rather confirmed than contradicted the opinion of Celsus, as most publications on this subject will sufficiently prove to an accurate observer. For, notwithstanding the multiplicity of pulses which have been enumerated, it is to the different degrees of irritability in constitutions that the variety of pulses is owing, with respect to their being quick or slow; every accident that happens to the body, and every affection in the mind, having an influence on them; so that very little can be determined from them in practice. The hard and the soft pulse are very often owing to a quantity of fat, or of a cellular membrane being situated betwixt the artery and the finger, or from the almost total absence of these in this situation.—The full and the small pulses are owing chiefly

to the different diameters of the arteries; and except the quick, the slow, and irregular pulses, there are none of the kinds which are so ingeniously distinguished by authors, but that will, on proper enquiry, be found fallacious.

There are adults, in health, whose pulse exceed not forty strokes in a minute; others, whilst they are at rest, have a pulse so quick that it may be counted to 120; and during the presence of a fever, the pulse has been observed in some instances to beat 220 times in the same period. We speak here of the human subject, the pulse in brute animals varying considerably in different species.

The indications of the pulse are generally of importance in veterinary as in human medicine; for by that we can judge of the state of the circulating system, the phenomena of diseases, the patient's strength or weakness, &c.

The following table is given by the late Dr. George Fordyce; and we apprehend it will answer a very useful purpose in affording a precise meaning to the various epithets applied to the pulsations of the arteries in diseases.

| <i>It indicates,</i>                                                              | <i>by</i>     | <i>It is called</i> |
|-----------------------------------------------------------------------------------|---------------|---------------------|
| 1. The strength of the heart's contraction -                                      | Strength.     | Strong.             |
| 2. The quantity of blood thrown out at each contraction - - - - -                 | Weakness.     | Weak.               |
| 3. The number of contractions - - - - -                                           | Fulness.      | Full.               |
| 4. The regularity of its action as to strength, quantity, or frequency. - - - - - | Smallness.    | Small.              |
|                                                                                   | Frequency.    | Frequent.           |
|                                                                                   | Slowness.     | Slow.               |
|                                                                                   | Regularity.   | Regular.            |
|                                                                                   | Irregularity. | Irregular.          |
|                                                                                   | Intermission. | Intermittent.       |
| 5. The strength of the action of the arteries -                                   | Hardness.     | Hard.               |
|                                                                                   | Softness.     | Soft.               |
|                                                                                   | Redoubling.   | Redoubling.         |
|                                                                                   | Trembling.    | Tremulous.          |
| 6. The irritability of the vessels - - - - -                                      | Quickness.    | Quick.              |
|                                                                                   | Regularity.   | Regular.            |
|                                                                                   | Slowness.     | Slow.               |
| 7. The medium diameter of the arteries -                                          | Dilatation.   | Great.              |
|                                                                                   | Contraction.  | Small.              |
| 8. The quantity of blood in the vessels -                                         | Oppression.   | Oppressed.          |
|                                                                                   | Smallness.    | Empty.              |
| 9. The contraction of the capillaries - - - - -                                   | Obstruction.  | Obstructed.         |
|                                                                                   | Freedom.      | Free.               |

This table needs no explanation; though it is in fact no easy matter, in many cases, to make the proper distinctions. In attempting to decide on the state of the pulse, it is of importance too, to know the usual pulsations of the patient when in health; as these differ materially in different subjects. The usual healthy pulse of the horse is about forty strokes in a minute.

PULSE signifies, 1. Oscillation; vibration; alternate expansion and contraction (*Newton*). 2. To feel one's PULSE. To try or know one's mind artfully. 3. (from *pull*.) Leguminous

plants. Plants not reaped but *pulled* or *plucked* (*Milton*).

To PULSE. *v. n.* (from the noun.) To beat as the pulse (*Ray*).

PULSION. *s.* (from *pulsus*, Latin.) The act of driving or forcing forward: in opposition to suction or traction (*More*).

PULTENEY (William), earl of Bath, was born in 1682. He was an eloquent opposer of the ministry in Anne's reign, and at the accession of George I. he was made secretary at war; but after some years of co-operation with Walpole, he disagreed with him in his measures for ad-

vancing the interests of Hanover at the expence of England. Difference of opinion produced hatred, so that Walpole's measures were opposed with personal virulence, and the king at last struck off Pulteney from the list of privy counsellors. This increased the popularity of Pulteney, and his sarcasms were pointed with the most powerful effect against the minister, who often declared that he dreaded his tongue more than another man's sword. Walpole was disgraced in 1741, and Pulteney rose in his seat, and was made earl of Bath; but when he got into place, he lost his popularity. He died 1764. He was concerned in the Craftsman, and wrote some political pamphlets.

**PULTENEY** (Richard), of Loughborough, Leicestershire, after practising as an apothecary at Leicester, took his medical degrees at Edinburgh, 1764. He settled at Blandford, where he acquired reputation. He was fellow of the Royal Society, and died 1801, aged 71. He is author of a general view of the life and writings of Linnæus, 1781—historical and biographical sketches of the progress of botany in England, 2 vols. 8vo. and he made valuable communications to the history of Leicestershire by Mr. Nichols, and to that of Dorsetshire by Hutchins. He also contributed to the Gentleman's Magazine by various dissertations on antiquities, and especially on history.

**PULTENÆA**, in botany, a genus of the class decandria, order monogynia. Calyx five-toothed, with an appendix on each side; corol papilionaceous, with the wings shorter than the standard; legume one-celled, two-seeded. Six species, shrubs of New Holland. See Nat. Hist. Pl. CXXXIV.

**PULTOUSK**, a town of Poland, in the palatinate of Masovia. In 1807, a battle was fought here between the French and Russians, in which both sides claimed the victory. It is seated on the Narew, 30 miles N. of Warsaw.

**PULTOWA**, a fortified town of the Ukraine, famous for a battle in 1709, between Peter the great and Charles XII. of Sweden, wherein the latter was totally defeated. It is 100 miles S.W. of Belgorod. Lon. 34. 25 E. Lat. 49. 26 N.

**PULVERARIA**, in botany, a tribe of algæ, belonging to the genus *LEPRARIA*, which see.

**PULVERABLE**. *a.* (from *pulveris*, Lat.) Possible to be reduced to dust (*Boyle*).

**PULVERIZATION**. *s.* (from *pulverize*.) The act of powdering; reduction to dust or powder.

To **PULVERIZE**. *v. n.* (from *pulveris*, Lat.) To reduce to powder; to reduce to dust (*Boyle*).

**PULVERULENCE**. *s.* (*pulverulentia*, Latin.) Dustiness; abundance of dust.

**PULVIL**. *s.* (*pulvillum*, Latin.) Sweet scented powder (*Gay*).

To **PULVIL**. *v. a.* (from the noun.) To sprinkle with perfumes in powder (*Congreve*).

**PULVIS**, in medicine, a powder. The following are the chief:

**PULVIS ALOES CUM CANELLA**. A cathartic, deobstruent powder, possessing stimulating and aloeic properties.

**P. ALOES CUM FERRO**. This possesses aperient and deobstruent virtues; and is mostly given in chlorosis and constipation.

**P. ALOES CUM GUAIACO**. A warm aperient, laxative powder, calculated for the aged, and those affected with dyspeptic gout, attended with costiveness and spasmodic complaints of the stomach and bowels.

**P. ALUMINIS COMPOSITUS**. An astrigent and tonic compound, mostly exhibited in uterine hæmorrhages, and debility of the primæ viæ.

**P. ANTIMONIALIS**. This preparation is called in the new chemical nomenclature, phosphas calcis stibiatus. It is in high esteem as a febrifuge, sudorific, and antispasmodic; and, under the name of James's powder, has been long sold as a secret medicine. The diseases in which it is mostly exhibited are most species of asthenic and exanthematous fevers, acute rheumatism, gout, diseases arising from obstructed perspiration, dysuria, nervous affections, and spasms.

**P. AROMATICUS**. An elegant stimulant, carminative, and stomachic powder.

**P. ASARI COMPOSITUS**. This powder is used as an errhine in diseases of the head, or to promote sneezing, in order to rouse the actions of the system.

**P. CERUSSÆ COMPOSITUS**. This is mostly used in the form of collyrium, lotion, or injection, as a mucilaginous sedative.

**P. CHELARUM CANCRI COMPOSITUS**. An antacid and adstringent powder, mostly given to children with diarrhæa and acidity of the primæ viæ.

**P. CONTRAYERVÆ COMPOSITUS**. A febrifuge diaphoretic, mostly given in the dose of from one to two scruples in slight febrile affections.

**P. CRETÆ COMPOSITUS**. An astrigent, carminative, and stomachic powder exhibited in the cure of diarrhæa, pyrosis, and diseases arising from acidity of the bowels, inducing much pain.

**P. CRETÆ COMPOSITUS CUM OPIO**. The above powder, with the addition of opium, in the proportion of one grain to two scruples.

**P. IPECACUANHÆ COMPOSITUS**. A diaphoretic powder, similar to that of Dr. Dover, which gained such repute in the cure of rheumatism, and other diseases arising from obstructed perspiration and spasm.

**P. JALAPPÆ COMPOSITUS**. A saline purgative.

**P. MYRRHÆ COMPOSITUS**. A stimulant, antispasmodic, and emmenagogue powder, mostly exhibited in the dose of from fifteen grains to two scruples, in uterine obstructions and hysterical affections.

**P. OPIATUS**. An absorbent and anodyne.

**P. SCAMMONII COMPOSITUS**. From ten to fifteen grains are exhibited as a stimulating cathartic.

**PULVIS SCAMMONII CUM ALOE.** A stimulating cathartic, in the dose of from ten to fifteen grains.

**P. SCAMMONII CUM CALOMELANE.** A vermifugal cathartic, in the dose of from ten to twenty grains.

**P. SENNÆ COMPOSITUS.** A saline stimulating cathartic.

**P. TRAGACANTHÆ COMPOSITUS.** A very useful demulcent powder, which may be given in the dose of a drachm in coughs, diarrhæas, stranguy, &c.

**P. FULMINANS,** a fulminating powder; a solution of silver in nitric acid, precipitated by lime-water, and then dried and washed with a solution of pure ammonia. See **ARGENTUM.**

**PUMICE-STONE,** in mineralogy, a species of **LAVA**, which see.

**PUMMEL.** s. See **POMMEL.**

**PUMP,** a hydraulic machine for raising water by means of the pressure of the atmosphere. It would be an entertaining and not an uninteresting piece of information to learn the progressive steps by which the ingenuity of man has invented the various methods of raising water. A pump must be considered as the last step of this progress. Common as it is, and overlooked even by the curious, it is a very abstruse and refined invention. Nothing like it has been found in any of the rude nations whom the restless spirit of the Europeans has discovered, either in the new continent of America or the islands of the Pacific Ocean. Nay, it was unknown in the cultivated empire of China at the time of our arrival there by sea; and it is still a rarity every where in Asia, in places unfrequented by the Europeans. It does not appear to have been known by the Greeks and Romans in early times; and perhaps it came from Alexandria, where physical and mathematical science was much cultivated by the Greek school under the protection of the Ptolemies. The performances of Ctesibius and Hero are spoken of by Pliny and Vitruvius as curious novelties. It is perhaps not difficult to trace the steps by which those mechanicians were led to the invention. The Egyptian wheel was a common machine all over Asia, and is still in use in the remotest corners, and was brought by the Saracens into Spain, where it is still very common under its common name *noría*. The Danish missionaries found in a remote village in the kingdom of Siam the immediate offspring of the *noría* (*Lettres Edifiantes et Curieuses*). It was a wheel turned by an ass, and carrying round, not a string of earthen pots, but a string of wisps of hay, which it drew through a wooden trunk. This rude chain-pump was in frequent use for watering the rice fields. It is highly probable that it is of great antiquity, although we do not recollect its being mentioned by any of the Greek or Roman writers. The Arabs and Indians were nothing less than innovators; and we may suppose with great safety, that what arts we now find among them they possessed in very remote periods. Now the step from this to the pump is but short, though it is nice and refined; and the forcing pump of Ctesibius is the easiest and most natural.

Let **AB** (plate 145, fig. 4.) be the surface of the water in the well, and **D** the height where it is to be delivered. Let **DC** be a long wooden trunk, reaching as deep under water as possible. Let the rope **EF** be fitted with its knot of hay **F**. When it

is drawn up through the trunk, it will bring up along with it all the water lying between **C** and **A**, which will begin to run out by the spout **D** as soon as the knot gets to **G**, as far below **D** as **C** is below **A**. All this is very obvious; and it required but little reflection to be assured, that if **F** was let down again, or pushed down, by a rod instead of a rope, it would again perform the same office. Here is a very simple pump. And if it was ever put in practice, it behoved to show the supporting power of the atmosphere, because the water would not only be lifted by the knot, but would even follow it. The imperfection of this pump behoved to appear at first sight, and to suggest its remedy. By pushing down the knot **F**, which we shall henceforward call the piston, all the force expended in lifting up the water between **A** and **G** is thrown away, because it is again let down. A valve **G**, at the bottom, would prevent this. But then there must be a passage made for the water by the lateral tube **KBD** (fig. 5.). And if this be also furnished with a valve **H**, to prevent its losing the water, we have the pump of Ctesibius, as sketched in fig. 2. The valve is the great refinement: but perhaps even this had made its appearance before in the *noría*. For, in the more perfect kinds of these machines, the pots have a stop or valve in their bottom, which hangs open while the pot descends with its mouth downwards, and then allows it to fill readily in the cistern; whereas without the valve, it would occasion a double load to the wheel. If we suppose that the valve had made its appearance so early, it is not improbable that the common pump sketched in fig. 3 was as old as that of Ctesibius. In this place we shall first give a short description of the chief varieties of these engines, considering them in their simplest form, and we shall explain in very general terms their mode of operation. We shall then give a concise and popular theory of their operation, furnishing principles to direct us in their construction; and we shall conclude with the description of a few peculiarities which may contribute to their improvement or perfection.

There are but two sorts of pumps which essentially differ; and all the varieties that we see are only modifications of these. One of these original pumps has a solid piston; the other has a piston with a perforation and a valve. We usually call the first a forcing pump, and the second a lifting or sucking pump.

Fig. 5. is a sketch of the forcing pump in its most simple form and situation. It consists of a hollow cylinder, **ACc a**, called the working barrel, open at both ends, and having a valve **G** at the bottom, opening upwards. This cylinder is filled by a solid piston **EF**, covered externally with leather or tow, by which means it fits the box of the cylinder exactly, and allows no water to escape by its sides. There is a pipe **KHD**, which communicates laterally with this cylinder, and has a valve at some convenient place **H**, as near as possible to its junction with the cylinder. This valve also opens upwards. This pipe, usually called the rising pipe, or main, terminates at the place **D**, where the water must be delivered.

Now suppose this apparatus set into the water, so that the upper end of the cylinder may be under or even with the surface of the water **AB**; the water will open the valve **G**, and after filling the barrel and lateral pipe, will also open the valve **H**, and at last stand at an equal height within and without. Now let the piston be put in, at the top of the working barrel, and thrust down to **K**. It

will push the water before it. This will shut the valve G, and the water will make its way through the valve H, and fill a part B *b* of the rising pipe, equal to the internal capacity of the working barrel. When this downward motion of the piston ceases, the valve H will fall down by its own weight and shut this passage. Now let the piston be drawn up again: the valve H hinders the water in the rising pipe from returning into the working barrel. But now the valve G is opened by the pressure of the external water, and the water enters and fills the cylinder as the piston rises. When the piston has got to the top, let it be thrust down again: the valve G will again be shut, and the water will be forced through the passage at H, and rise along the main, pushing before it the water already there, and will now have its surface at L. Repeating this operation, the water must at last arrive at D, however remote, and the next stroke would raise it to *e*; so that during the next rise of the piston the water in *e* D will be running off by the spout.

The effect will be the same whatever is the position of the working barrel, provided only that it be under water. It may lie horizontally or sloping, or it may be with its mouth and piston rod undermost. It is still the same forcing pump, and operates in the same manner and by the same means, viz. the pressure of the surrounding water.

The external force which must be applied to produce this effect is opposed by the pressure exerted by the water on the opposite face of the piston. It is evident, from the common laws of hydrostatics, that this opposing pressure is equal to the weight of a pillar of water, having the face of the piston for its base, and the perpendicular height *d* A of the place of delivery above the surface of the water AB in the cistern for its height. The form and dimensions of the rising pipe are indifferent in this respect, because heavy fluids press only in the proportion of their perpendicular height. Observe that it is not *d* F, but *d* A, which measures this pressure, which the moving force must balance and surmount. The whole pressure on the under surface F *f* of the piston is indeed equal to the weight of the pillar *d* F *f* *b*; but part of this is balanced by the water AF *f* *a*. If indeed the water does not get into the upper part of the working barrel, this compensation does not obtain. While we draw up the piston, this pressure is removed, because all communication is cut off by the valve H, which now bears the whole pressure of the water in the main. Nay, the ascent of the piston is even assisted by the pressure of the surrounding water. It is only during the descent of the piston therefore that the external force is necessary. This however merely regards the state of equilibrium, and not that of actual working.

The simplest form and situation of the lifting pump is represented by the sketch fig. 6. The pump is immersed in the cistern till both the valve G and piston F are under the surface AB of the surrounding water. By this means the water enters the pump, opening both valves, and finally stands on a level within and without.

Now draw up the piston to the surface A. It must lift up the water which is above it (because the valve in the piston remains shut by its own weight); so that its surface will now be at *a*. A *a* being made equal to AF. In the mean time, the pressure of the surrounding water forces it into the working barrel, through the valve G; and the barrel is now filled with water. Now, let the piston be pushed down again; the valve G immediately

shuts by its own weight, and in opposition to the endeavours which the water in the barrel makes to escape this way. This attempt to compress the water in the barrel causes it to open the valve F in the piston: or rather, this valve yields to our endeavour to push the piston down through the water in the working barrel. By this means we get the piston to the bottom of the barrel; and it has now above it the whole pillar of water reaching to the height *a*. Drawing up the piston to the surface A a second time, must lift this double column along with it, and its surface now will be at *b*. The piston may again be thrust down through the water in the barrel, and again drawn up to the surface; which will raise the water to *c*. Another repetition will raise it to *d*; and it will now show itself at the intended place of delivery. Another repetition will raise it to *e*; and while the piston is now descending to make another stroke, the water in *e* *d* will be running off through the spout D; and thus a stream will be produced, in some degree continual, but very unequal. This is inconvenient in many cases: thus, in a pump for domestic uses, such a hobbling stream would make it very troublesome to fill a bucket. It is therefore usual to terminate the main by a cistern LMNO, and to make the spout small. By this means the water brought up by the successive strokes of the piston rises to such a height in this cistern, as to produce an efflux by the spout nearly equable. The smaller we make the spout D the more equable will be the stream; for when the piston brings up more water than can be discharged during its descent, some of it remains in the cistern. This, added to the supply of next stroke, makes the water rise higher in the cistern than it did by the preceding stroke. This will cause the efflux to be quicker during the descent of the piston, but perhaps not yet sufficiently quick to discharge the whole supply. It therefore rises higher next stroke: and at last it rises so high, that the increased velocity of efflux makes the discharge precisely balance the supply. Now the quantity supplied in each stroke is the same, and occupies the same room in the cistern at top; and the surface will sink the same number of inches during the descent of the piston, whether that surface has been high or low at the beginning. But because the velocities of the efflux are as the square roots of the heights of the water above the spout, it is evident that a sink of two or three inches will make a smaller change in the velocity of efflux when this height and velocity are great.

It is evident that the force necessary for this operation must be equal to the weight of the pillar of water *d* A A D, if the pipe be perpendicular. If the pump be standing aslope, the pressure which is to be balanced is still equal to the weight of a pillar of water of this perpendicular height, and having the surface of the piston for its base.

Such is the simplest, and, we may add, by far the best, form of the forcing and lifting pumps; but it is not the most usual. Circumstances of convenience, economy, and more frequently of fancy and habit, have caused the pump-makers to deviate greatly from this form. It is not usual to have the working barrel in the water; this, especially in deep wells, makes it of difficult access for repairs, and requires long piston rods. This would not do in a forcing pump, because they would bend.

We have supposed, in our account of the lifting pump, that the rise of the piston always terminated at the surface of the water in the cistern. This we did in order that the barrel might always be filled by the pressure of the surrounding water. But

## P U M P.

let us suppose that the rise of the piston does not end here, and that it is gradually drawn up to the very top: it is plain that the pressure of the atmosphere is by this means taken off from the water in the pipe (see PNEUMATICS), while it remains pressing on the water of the cistern. It will therefore cause the water to follow the piston as it rises through the pipe, and it will raise it in this way 33 feet at a medium. If, therefore, the spout D is not more than 33 feet above the surface of the water in the cistern, the pipe will be full of water when the piston is at D. Let it be pushed down to the bottom; the water will remain in the pipe, because the valve G will shut: and thus we may give the piston a stroke of any length not exceeding 33 feet. If we raise it higher than this, the water will not follow; but it will remain in the pipe, to be lifted by the piston, after it has been pushed down through it to the bottom.

But it is not necessary, and would be very inconvenient, to give the piston so long a stroke. The great use of a pump is to render effectual the reciprocation of a short stroke which we can command, while such a long stroke is generally out of our power. Suppose that the piston is pushed down only to  $b$ ; it will then have a column  $bf$  incumbent on it, and it will lift this column when again drawn up. And this operation may be repeated like the former, when the piston was always under water; for the pressure of the atmosphere will always cause the water to follow the piston to the height of 33 feet.

Nor is it necessary that the fixed valve G be placed at the lower orifice of the pipe, nor even under water. For, while things are in the state now described, the piston drawn up to  $f$ , and the whole pipe full of water; if we suppose another valve placed at  $b$  above the surface of the cistern, this valve can do no harm. Now let the piston descend, both valves G and  $b$  will shut. G may now be removed, and the water will remain supported in the space  $bG$  by the air; and now the alternate motions of the piston will produce the same effect as before.

We found in the former case that the piston was carrying a load equal to the weight of a pillar of water of the height AD, because the surrounding water could only support it at its own level. Let us see what change is produced by the assistance of the pressure of the atmosphere. Let the under surface of the piston be at  $b$ ; when the piston was at  $f$ , 33 feet above the surface of the cistern, the water was raised to that height by the pressure of the atmosphere. Suppose a partition made at  $b$  by a thin plate, and all the water above it taken away. Now pierce a hole in this plate. The pressure of the atmosphere was able to carry the whole column  $fa$ . Part of this column is now removed, and the remainder is not a balance for the air's pressure. This will therefore cause the water to spout up through this hole and rise to  $f$ . Therefore the under surface of this plate is pressed up by the contiguous water with a force equal to the weight of that pillar of water which it formerly supported; that is, with a force equal to the weight of the pillar  $fb$ . Now, the under surface of the piston, when at  $b$ , is in the same situation. It is pressed upwards by the water below it, with a force equal to the weight of the column  $fb$ ; but it is pressed downwards by the whole pressure of the atmosphere, which presses on all bodies; that is, with the weight of the pillar  $fa$ . On the whole, therefore, it is pressed downwards by a force equal to the difference of the weights of the pillars  $fa$

and  $fb$ ; that is, by a force equal to the weight of the pillar  $ba$ .

It may be conceived better perhaps in this way. When the piston was under the surface of the water in the cistern, it was equally pressed on both sides, both by the water and atmosphere. The atmosphere exerted its pressure on it by the intervention of the water; which being, to all sense, a perfect fluid, propagates every external pressure undiminished. When the piston is drawn up above the surface of the pit-water, the atmosphere continues to press on its upper surface with its whole weight, through the intervention of the water which lies above it; and its pressure must therefore be added to that of the incumbent water. It also continues to press on the under surface of the piston by the intervention of the water; that is, it presses this water to the piston. But, in doing this, it carries the weight of this water which it is pressing on the piston. The pressure on the piston therefore is only the excess of the whole pressure of the atmosphere above the weight of the column of water which it is supporting. Therefore the difference of atmospheric pressure on the upper and under surfaces of the piston is precisely equal to the weight of the column of water supported in the pipe by the air. It is not, however, the individual weight of this column that loads the piston; it is the part of the pressure of the atmosphere on its upper surface, which is not balanced by its pressure on the under surface.

In attempting therefore to draw up the piston, we have to surmount this unbalanced part of the pressure of the atmosphere, and also the weight of the water which lies above the piston, and must be lifted by it: and thus the whole opposing pressure is the same as before, namely, the weight of the whole vertical pillar reaching from the surface of the water in the cistern to the place of delivery. Part of this weight is immediately carried by the pressure of the atmosphere; but, in lieu of it, there is an equal part of this pressure of the atmosphere abstracted from the under surface of the piston, while its upper surface sustains its whole pressure.

So far, then, these two states of the pump agree. But they differ exceedingly in their mode of operation; and there are some circumstances not very obvious which must be attended to, in order that the pump may deliver any water at the spout D. This requires, therefore, a serious examination.

Let the fixed valve G (fig. 7.) be supposed at the surface of the cistern water. Let  $Mn$  be the lowest, and  $Nz$  the highest, positions of the piston, and let  $HA = h$  be the height of a column of water equiponderant with the atmosphere.

When the pump is filled, not with water, but with air, and the piston is in its lowest position, and all in equilibrio, the internal air has the same density and elasticity with the external. The space  $MA\ a m$ , therefore, contains air of the common density and elasticity. These may be measured by  $h$ , or the weight of a column of water whose height is  $h$ . Now, let the piston be drawn up to  $Nz$ . The air which occupied the space  $MA\ a m$  now occupies the space  $NA\ a n$ , and its density

is now  $\frac{MA\ a m}{NA\ a n}$ . Its elasticity is now diminished,

being proportionable to its density (see PNEUMATICS), and no longer balances the pressure of the atmosphere. The valve G will therefore be forced up by the water, which will rise to some height

# P U M P.

SA. Now, let the piston descend again to Mm. It cannot do this with its valve shut; for when it comes down so far as to reduce the air again to its common density, it is not yet at M, because the space below it has been diminished by the water which got into the pipe, and is retained there by the valve G. The piston valve, therefore, opens by the air which we thus attempt to compress, and the superfluous air escapes. When the piston has got to M, the air is again of the common density, and occupies the space MS sm. Now draw the piston up to N. This air will expand into the space NS sn, and its density will be reduced to  $\frac{MS sm}{NS sn}$ , and its elasticity will no longer balance

the pressure of the atmosphere, and more water will enter, and it will rise higher. This will go on continually. But it may happen that the water will never rise so high as to reach the piston, even though not 33 feet above the water in the cistern: for the successive diminutions of density and elasticity are a series of quantities that decrease geometrically, and therefore will have a limit. Let us see what determines this limit.

At whatever height the water stands in the lower part of the pipe, the weight of the column of water SA as, together with the remaining elasticity of the air above it, exactly balances the pressure of the atmosphere (see PNEUMATICS). Now the elasticity of the air in the space NS sn is equal to

$h \times \frac{MS sm}{NS sn}$ . Therefore, in the case where the

limit obtains, and the water rises no further, we

must have  $h = AS + h \frac{MS sm}{NS sn}$ , or, because the

column is of the same diameter throughout,  $h =$

$AS + h \frac{MS}{NS}$  and  $\frac{MS}{NS} h = h - AS$ , = HS, and

NS: MS = HA: HS, and NS-MS: NS = HA-HS: HA, or NM: NS = AS: AH, and NM × AH = NS × AS.—Therefore, if AN, the distance of the piston in its slightest position from the water in the cistern, and NM the length of its stroke, be given, there is a certain determined height AS to which the water can be raised by the pressure of the air: for AH is a constant quantity; and therefore when MN is given, the rectangle AS × SN is given. If this height AS be less than that of the piston in its lowest position, the pump will raise no water, although AN may be less than AH. Yet the same pump will raise water very effectually, if it be first of all filled with water; and we have seen professional engineers much puzzled by this capricious failure of their pumps. A little knowledge of the principles would have prevented their disappointment.

To insure the delivery of water by the pump, the stroke must be such that the rectangle MN × AH may be greater than any rectangle that can be made of the parts of AN, that is, greater than the square of half AN. Or, if the length of the stroke be already fixed by other circumstances, which is a common case, we must make AN so short that the square of its half, measured in feet, shall be less than 33 times the stroke of the piston.

Suppose that the fixed valve, instead of being at the surface of the water in the cistern, is at S, or any where between S and A, the performance of the pump will be the same as before: but if it be placed any where above S, it will be very dif-

ferent. Let it be at T. It is plain that when the piston is pushed down from N to M, the valve at T prevents any air from getting down; and therefore, when the piston is drawn up again, the air contained in the space MT tm will expand into the

space NT tn, and its density will be  $\frac{MT}{NT}$ . This is less than  $\frac{MS}{NS}$ , which expresses the density of

the air which was left in the space TS st by the former operations.—The air, therefore, in TS st will also expand, will open the valve, and now the water will rise above S. The proportion of NS to NT may evidently be such that the water will even get above the valve T. This diminishes the space NT tn; and therefore, when the piston has been pushed down to M, and again drawn up to N, the air will be still more rarefied, and the water will rise still higher. The foregoing reasoning, however, is sufficient to show that there may still be a height which the water will not pass, and that this height depends on the proportion between the stroke of the piston and its distance from the water in the cistern. We need not give the determination, because it will come in afterwards in combination with other circumstances. It is enough that the reader sees the physical causes of this limitation: and, lastly, we see plainly that the utmost security will be given for the performance of the pump, when the fixed valve is so placed that the piston, when in its lowest position, shall come into contact with it. In this case the rarefaction of the air will be the completest possible; and, if there were no space left between the piston and valve, and all were perfectly air-tight, the rarefaction would be complete, and the valve might be any thing less than 33 feet from the surface of the water in the cistern.

But this perfect contact and tightness is unattainable; and though the pump may be full of water, its continual downward pressure causes it to filtrate slowly through every crevice, and the air enters through every pore, and even disengages itself from the water, with which a considerable portion had been chemically combined. The pump by this means loses water, and it requires several strokes of brisk working to fill it again: and if the leathers have become dry, so much admission may be given to the air, that the pump will not fill itself with water by any working. It is then necessary to pour water into it, which shuts up these passages, and soon sets all to rights again. For these reasons, it is always prudent to place the fixed valve as low as other circumstances will permit, and to make the piston-rod of such a length, that when it is at the bottom of its stroke it shall be almost in contact with the valve. When we are not limited by other circumstances, it is evident that the best possible form is to have both the piston and the fixed valve under the surface of the water of the cistern. In this situation they are always wet and air-tight. The chief objection is, that by this disposition they are not easily come at when needing repair. This is a material objection in deep mines. In such situations, therefore, we must make the best compensation of different circumstances that we can. It is usual to place the fixed valve at a moderate distance from the surface of the water, and to have a hole in the side of the pipe, by which it may be got out. This is carefully shut up by a plate firmly screwed on, with leather or cement between the parts. This is called the *clack door*. It would, in every case,

be very proper to have a fixed valve in the lower end of the pipe. This would combine all advantages. Being always tight, the pipe would retain the water, and it would leave to the valve above it its full effect of increasing the rarefaction. A similar hole is made in the working barrel, a little above the highest position of the piston. When this needs repair, it can be got at through this hole, without the immense trouble of drawing up the whole rods.

Thus we have conducted the reader step by step, from the simplest form of the pump to that which long experience has at last selected as the most generally convenient. We might now proceed to detail the minute particulars in the construction of these pumps, as well as describe a variety of others: but as this would extend the present article beyond its assigned limits, we beg to refer the reader to Bossut's *Hydrodynamics*, Prony's *Hydraulic Architecture*, and Gregory's *Mechanics*, for much interesting information; and simply call his attention here to the two following varieties in the construction.

*Chain pump*, consists of a long chain, equipped with a sufficient number of valves, at proper distances, which working upon two wheels, one above and the other below, passes downward through a wooden tube, and returns upward through another. It is managed by a long winch or roller, whereon several men may be employed at once, and thus it discharges, in a limited time, a much greater quantity of water than the common pump, and with less fatigue and inconvenience to the labourers. This machine was formerly exposed to several disagreeable accidents, by nature of its then construction. The chain was of too complicated a fabric, and the spoked wheels, employed to wind it up from the ship's bottom, were deficient in a very material circumstance, viz. some contrivance to prevent the chain from sliding or jerking back upon the surface of the wheel, which frequently happened when the valves were charged with a considerable weight of water, or when the pump was violently worked. The links were evidently too short, and the unmechanical manner in which they were connected exposed them to a great friction in passing round the wheels. Hence they were sometimes apt to break or burst asunder in very dangerous situations, when it was extremely difficult, and sometimes impracticable to repair the chain. Of late, however, some considerable improvements have been made by Mr. Cole, under the direction of Captain Bentinck. The chain of this machine is more simple and mechanical, and less exposed to danger. It appears to have been first applied to the pump by Mr. Mylne, to exhaust the water from the caissons at Blackfriars Bridge. It was thence transferred to the marine by Captain Bentinck, after having received some material additions to answer that service. The principal superiority of this pump to the former is, 1. That the chain is more simple and easily worked, and consequently less exposed to injuries by friction. 2. That the chain is secured upon the wheel, and thereby prevented from jerking back when charged with a column of water. 3. That it may be easily taken up and repaired when broken or choked with ballast, &c. And, 4. That it discharges a much greater quantity of water with an inferior number of men. This has been proved by experience, when two men (instead of four) discharged a tun of water in fifty-five seconds.

*Double barrelled force pump*, is the same in principle as the ordinary forcing pump; only that two barrels are connected together for the advantage

of raising a constant stream of water. As the construction of a pump of this kind is important, we have appropriated the upper part of plate 124 to its explanation. Figs. 1 and 2 are plans, fig. 3 an elevation, fig. 4 a section, and figs. 5 and 6 separate figures of a valve of the pump (see Part 38). AA, figs. 1, 3, 4, are the barrels, which are bored out truly cylindrical: if the pump is small, the barrels are usually made of brass; but for larger work cast iron is used. They have a flanch or projecting ring at their lower ends to screw them to the rest of the pump. Each barrel is fitted with a piston or forcer, which consists of three metallic plates secured to a rod B, fig. 4: the middle plate is turned true and fitted as accurately as possible to the barrel: the upper and lower plates are somewhat smaller. Two round pieces of leather larger than the barrel are placed above and below the middle plate, being held fast between it and the upper and lower plates. When forced into the barrels these leathers turn up and down round the upper and lower plates, forming two cups of leather, which accurately fit the barrel, and will not permit any fluid to pass by them. The barrels are screwed down by their flanches to two chambers BD, shewn in plano in fig. 2, which are exactly similar to each other. They have each three apertures. The first is that by which they communicate with the barrel A; another immediately under this brings the water to the pump; and the third is that out of which the water issues when the forcer of the pump descends. HD, figs. 3 and 4, is the suction hamper which is common to both barrels: it has a pipe E from its lower part, terminating in a flanch to screw on the pipe to bring water to the pump. The upper flanch has two valves *gh*, fig. 2, in it, one under each barrel. One of these is shewn in the section fig. 4: it is made in the manner of figs. 5 and 6, where *aa* represents a brass ring turned out very true in the lathe, leaving a bar *b* across it, which is perforated with a hole to receive the spindle or tail of the valve *d*: the valve is fitted into the valve seat *aa* by grinding, so as to be perfectly air-tight, that it may retain any fluid which may pass through it. Another pair of these valves *ef*, fig. 2, is fitted into the chambers BD, and is covered by the forcing chamber I, which is exactly similar to the suction-piece. The parts of the pump are fastened together by screws and nuts, as will be understood by inspection of the figures. The whole pump is supported on two ground-cills GG by means of two iron bearers LL, screwed under the flanches of the pump and bolted down upon the ground-cills. The action of this pump is simple: when the piston or forcer of one barrel is raised, it causes a vacuum in it, and the pressure of the atmosphere forces the water up the suction-pipe (if not more than 30 or 33 feet), opens the valve *g* or *h* in the bottoms of the barrel, and fills it with water: on the descent of the forcer the lower valve shuts and the forcing valve *e* or *f* opens; the water the barrel contained is driven through it into the forcing chamber, and thence to any place whither the forcing pipe is carried. On the re-ascend of the forcer the lower valve opens, and the shutting of the forcing valve prevents the water returning into the barrel: the two forcers work up and down alternately, so that while one barrel is sending water up the force-pipe, the other is lifting it up the suction-pipe: in this manner the pump will raise a nearly constant stream of water if the forcers are worked in a proper manner, which is best done by means of cranks.

*Double Barrell'd Force Pump.*

*Fig. 1.*

*Plan.*

*Fig. 2.*

*Plan.*

*Elevation.*

*Fig. 3.*

*Fig. 5.*

*Fig. 6.*

*Section.*

*Fig. 4.*

*Three Barrell'd*

*Lift Pump.*

*Fig. 7.*

*Fig. 9.*

*Fig. 8.*

Figs. 7, 8, and 9, represent a *three-barrelled lift pump*, which differs from the force-pump in having the water drawn up through the barrel, instead of being taken in and forced out at the bottom again. AAA are the three barrels screwed upon the suction chamber B, which bring the water to them through the pipe D: from the top of each barrel a crooked passage *a*, fig. 8, proceeds, and the forcing chamber E covers them all. The top of each barrel is covered by a lid, containing a stuffing box *b*, which is a cavity to contain a piece of leather and a screw to hold it firmly round the pump rod *d*, that the water may not leak round the rod, though at the same time it may move freely up and down through the stuffing box. The bucket *e*, fig. 9, which is fixed to the pump rod *d*, is fitted round with leather that it may not leak, and contains a valve in it similar to those of the force-pump. In the bottom of each barrel a leather valve is placed closing a hole in the top of the suction chamber B, and preventing the return of any water that the barrel may contain. Another leather valve is placed over each of the passages *a*. When the pumps are full of water, by drawing up the bucket, its valve closes, and the water contained above the bucket is lifted through the valves in the forcing chamber E into the pipes: at the same time a vacuum is caused in the barrel below the piston, which causes the water to pass through the lower valve to refill it. On the descent of the bucket, its valve opens, and it passes down through the water which the barrel contains ready for another stroke. The forcing valves in E are not absolutely necessary to the operation of the pump, as the lower valves would retain the water in the barrels equally well; but they are useful as a security in case the lower valves should fail: and when the lids of the barrels are removed for the purpose of repairing the leather of the buckets, they prevent the descent of the water contained in the force-pipe. This pump, like the others, should be worked by means of cranks; but by having three barrels a more equable flow of water can be obtained than in a two-barrelled engine.

**PUMP (Air).** See **AIR-PUMP**.

**PUMP**, denotes also a shoe with a thin sole and low heel.

**To PUMP. v. n.** (*pompen*, Dutch.) To work a pump; to throw out water by a pump (*Deceit of Piety*).

**To PUMP. v. a.** 1. To raise or throw out as by means of a pump (*Blackmore*). 2. To examine artfully by sly interrogatories, so as to draw out any secrets (*Otway*).

**PUMPER. s.** (from *pump*.) The person or the instrument that pumps (*Boyle*).

**PUMPKIN**, or **PUMPKIN**, in botany. See **CUCURBITA**.

**PUN. s.** An equivocation; a quibble; an expression where a word has at once different meanings (*Addison*).

**To PUN. v. n.** (from the noun.) To quibble; to use the same word at once in different senses (*Dryden*).

**To PUNCH. v. a.** (*poingonner*, French.) To bore or perforate by driving a sharp instrument (*Wiseman*).

**PUNCH**, an instrument of iron or steel, used in several arts, for the piercing or stamping holes in plates of metals, &c. being so contrived as not only to perforate, but to cut out and

take away the piece. The punch is a principal instrument of the metal button-makers, shoe-makers, &c.

**PUNCH**, is also a name for a sort of compound drink, much used here, and in many parts abroad, particularly in Jamaica, and several other parts of the West Indies. Its basis is spring-water; which being rendered cooler, brisker, and more acid, with lemon or lime juice, and sweetened again to the palate with fine sugar, makes what they call sherbet; to which a proper quantity of spirituous liquor, as brandy, rum, or arrack, being added, the liquor becomes punch.

**PUNCH** signifies, 1. The buffoon or harlequin of the puppet-show (*Gay*). 2. In contempt or ridicule, a short fat fellow.

**PUNCHEON, PUNCHIN, or PUNCHION**, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraven either in creux or relievo, impressions whereof are taken on metal, or some matter, by striking it with a hammer on the end not engraven. There are various kinds of these puncheons used in the mechanical arts; such, for instance, are those of the goldsmiths, cutlers, pewterers, &c. The puncheon in coining, is a piece of iron steeled, whereon the engraver has cut in relievo the several figures, arms, effigy, inscription, &c. that there are to be in matrices, wherewith the species are to be marked. Minters distinguish three kinds of puncheons, according to the three kinds of matrices to be made; that of the effigy, that of the cross or arms, and that of the legend or inscription. The first includes the whole portrait in relievo; the second are small, such only containing a piece of the cross or arms; for instance, a fleur-de-lis, a harp, a coronet, &c. by the assemblage of all which the entire matrix is formed. The puncheons of the legend only contain each one letter, and serve equally for the legend on the effigy side and the cross side.

**PUNCHEON** is also used for several iron tools, of various sizes and figures, used by the engravers en creux on metals. Seal-engravers particularly use a great number for the several pieces of arms, &c. to be engraven, and many stamp the whole seal from a single puncheon.

**PUNCHEON**, is also a common name for all those iron instruments used by stone-cutters, sculptors, blacksmiths, &c. for the cutting, incising, or piercing their several matters. Those of sculptors and statuary serve for the repairing of statues when taken out of the moulds. The locksmiths use the greatest variety of puncheons; some for piercing hot, others for piercing cold; some flat, some square, some round, others oval, each to pierce holes of its respective figure in the several parts of locks.

**PUNCHEON**, in carpentry, is a piece of timber placed upright between two posts, whose bearing is too great; serving, together with them, to sustain some large weights. This term is also used for a piece of timber raised upright, under the ridge of a building, wherein the legs of a couple, &c. are jointed.

**PUNCHEON**, is also the name of a measure

for liquids. Rum is brought from the colonies in puncheons, which are large casks containing about 130 gallons.

**PUNCHER.** *s.* (from *punch*.) An instrument that makes an impression or hole (*Grew*).

**PUNCTA LACHRYMALIA**, in anatomy. Two small orifices, one of which is conspicuous in each eyelid, at the extremity of the tarsus, near the internal canthus.

**PUNCTATE LEAF.** Dotted leaf. See **PERFORATE**.

**PUNCTILIO.** *s.* A small nicety of behaviour; a nice point of exactness (*Addison*).

**PUNCTILIOUS.** *a.* (from *punctilio*.) Nice; exact; punctual to superstition (*Rog.*).

**PUNCTILIOUSNESS.** *s.* (from *punctilious*.) Nicety; exactness of behaviour.

**PUNCTO.** *s.* (*punto*, Spanish.) 1. Nice point of ceremony (*Bacon*). 2. The point in fencing (*Shakspeare*).

**PUNCTUAL.** *a.* (*punctuel*, French.) 1. Comprised in a point; consisting in a point (*Milton*). 2. Exact; nice; punctilious.

**PUNCTUALITY.** *s.* (from *punctual*.) Nicety; scrupulous exactness (*Howel*).

**PUNCTUALLY.** *ad.* (from *punctual*.) Nicely; exactly; scrupulously (*Ray*).

**PUNCTUALNESS.** *s.* (from *punctual*.) Exactness; nicety (*Felton*).

**PUNCTUATION**, the art of dividing a written composition into sentences, or parts of sentences, by points or stops, for the purpose of marking the different pauses which the sense requires.

The comma (,) represents the shortest pause; the semicolon (;) a pause double that of the comma; the colon (:) double that of the semicolon; and the period (.) double that of the colon. The precise duration of these pauses must depend on the degree of slowness or rapidity observed in reading; but the proportion between them should be ever invariable.

In order to determine clearly the application of the points, it is necessary to distinguish between a simple sentence and a compound sentence. A simple sentence contains only one finite verb: as, "Virtue refines the affections." A compound sentence has more than one finite verb expressed or implied, and therefore consists of two or more simple sentences connected together: as, "Virtue refines the affections; but vice debases them."

The comma is used to mark the pauses which occur in a simple sentence; the semicolon and the colon divide a compound sentence into the members which compose it; and the period is placed at the end of a sentence to denote that it is complete, and unconnected with that which follows.

In a simple sentence, when two or more words of the same sort, or belonging to the same part of speech, occur, they are parted by a comma: as, "Husband, wife, and children;" "open, generous, sincere;" "to read, mark, learn;" "to live soberly, righteously, and godly," &c.

Where the connection of the different parts

of a simple sentence is interrupted by necessary adjuncts, either to the subject or to the verb, the separation is generally marked by a comma: as, "To rouse mankind, when sunk in ignorance or superstition, and to encounter the rage of bigotry, armed with power, required the utmost vehemence of zeal, and a temper daring to excess."

The semicolon is used for dividing a compound sentence, and hence it occurs most generally in cases where the comma has preceded, and a greater pause is necessary: as, "Tribulation worketh patience; and patience, experience; and experience, hope." "He knew how to conciliate the most enterprising spirit, with the coolest moderation; the most obstinate perseverance, with the easiest flexibility; the most severe justice, with the greatest lenity; the greatest rigour in command, with the greatest affability of deportment; the highest capacity and inclination for science, with the most shining talents for action." In each of these examples the first clause forms a complete sentence, and what is expressed in it is understood in those which follow.

The colon divides a compound sentence into parts less connected than those which are separated by a semicolon. It may be properly applied in the three following cases:

1. When a member of a sentence is complete in itself, but is followed by some supplemental remark, or further illustration of the subject: as, "The knowledge of nature is only half the task of a poet: he must be acquainted likewise with all the modes of life."

2. When several semicolons have preceded: as, "Those who propagate evil reports frequently invent them; and it is no breach of charity to suppose this to be always the case; because no man who spreads detraction would scruple to produce it: and he who should diffuse poisons in a brook would scarce be acquitted of a malicious design, though he should allege that he received it of another who is doing the same elsewhere."

3. Where an example, a quotation, or a speech is introduced: as, "He was often heard to say: 'I have done with the world.'"

The period is employed to separate sentences which are not connected in construction; but it may be sometimes admitted, though they are joined by a copulative or disjunctive conjunction: as, "In passing judgment upon the characters of men, we ought to try them by the principles and maxims of their own age, and not by those of another. For, although virtue and vice are at all times the same, manners and customs vary continually."

Besides the points which mark the pauses in discourse, there are others, which denote a different modulation of voice in correspondence to the sense. These are,

The interrogation point ?

The exclamation point !

The parenthesis ( )

The interrogation and exclamation points are sufficiently explained by their names: they are indeterminate as to their duration, and may

in that respect be equivalent to a semicolon, a colon, or a period, as the sense requires. They generally mark an elevation of the voice.

The parenthesis is a clause introduced into the body of a sentence without affecting the construction. It marks a moderate depression of the voice, and may be marked with every point which the sense would require if the parenthetical characters were omitted. It ought to terminate with the same kind of stop which the member has that precedes it; and to contain that stop within the parenthetical marks: as, "He found them asleep again; (for their eyes were heavy;) neither knew they what to answer him."

Mr. J. Warburton has proved in the *Monthly Magazine* for September 1798, that the art of punctuation is not wholly modern, as many authors have affirmed. His proofs are as follows:

"Some species of pauses and divisions of sentences in speaking and writing must have been coeval with the knowledge of communicating ideas by sound or by symbols. Suidas says, that the period and the colon were discovered and explained by Thrasy-machus, about 380 years before the Christian era. Cicero says, that Thrasy-machus was the first who studied oratorical numbers, which entirely consisted in the artificial structure of periods and colons. It appears from a passage in Aristotle, that punctuation was known in his time. The learned Dr. Edward Bernard refers the knowledge of pointing to the time of that philosopher, and says, that it consisted in the different positions of one single point. At the bottom of a letter, thus, (A.) it was equivalent to a comma: in the middle (A.) it was equal to a colon; at the top (A) it denoted a period, or the conclusion of a sentence.

"This mode was easily practised in Greek manuscripts, while they were written in capitals. But when the small letters were adopted, that is, about the 9th century, this distinction could not be observed; a change was therefore made in the scheme of punctuation. 'Unciales literas hodierno usu dicimus eas in vetustis codicibus, quæ priscam formam servant, ac solutæ sunt, nec mutuo colligantur. Hujus modi literæ unciales observantur in libris omnibus ad nonum usque sæculum.'—*Montf. Palæog. Recens.* p. xii.

"According to Cicero, the ancient Romans, as well as the Greeks, made use of points. He mentions them under the appellation of 'librariorum notæ;' and in several parts of his works he speaks of 'interpunctæ clausulæ in orationibus,' of 'clausulæ atque interpuncta verborum,' of 'interpunctiones verborum,' &c.

"Seneca, who died A. D. 65, expressly says, that Latin writers, in his time, had been used to punctuation. 'Nos, cum scribimus interpungere consuevimus.' Muretus and Lipsius imagined that these words alluded to the insertion of a point after each word: but they certainly were mistaken; for they must necessarily refer to marks of punctuation in the division of sentences, because in the passage in which these

words occur, Seneca is speaking of one Q. Haterius, who made no pauses in his orations.

"According to Suetonius, in his *Illust. Gram.* Valerius Probus procured copies of many old books, and employed himself in correcting, pointing, and illustrating them; devoting his time to this and no other part of grammar. 'Multa exemplaria contracta emendare, ac distinguere et adnotare curavit; soli huit, nec ulli præterea, grammatices parti deditus.'

"It appears from hence, that in the time of Probus, or about the year 68, Latin manuscripts had not been usually pointed, and that grammarians made it their business to supply this deficiency.

"Quintilian, who wrote his celebrated treatise on oratory, about the year 88, speaks of commas, colons, and periods; but it must be observed, that by these terms he means clauses, members, and complete sentences, and not the marks of punctuation.

"Ælius Donatus published a treatise on grammar in the 4th century, in which he explains the distinctio, the media distinctio, and the subdistinctio; that is, the use of a single point in the various positions already mentioned.

"Jerom, who had been the pupil of Donatus, in his Latin Version of the Scriptures, made use of certain distinctions or divisions, which he calls cola and commata. It has, however, been thought probable, that these divisions were not made by the addition of any points or stops; but were formed by writing, in one line, as many words as constituted a clause, equivalent to what we distinguish by a comma or a colon. These divisions were called *στίχοι* or *ῥήματα*; and had the appearance of short irregular verses in poetry. There are some Greek manuscripts still extant, which are written in this manner."

**TO PUNCTULATE.** *v. n.* (*punctulum*, Latin.) To mark with small spots (*Woodward*).

**PUNCTUM DUPLEX** (Double point), in the higher geometry, a point where two branches of a curve intersect each other. See **CURVE**, **LEMNISCATE**, &c.

**PUNCTURE.** *s.* (*punctus*, Lat.) A small prick; a hole made with a very sharp point (*Brown*).

**PUNBLE.** *s.* A short and fat woman (*Ain.*).

**PUNDITS**, or **PENDITS**, learned Bramins devoted to the study of the Shanscrit language, and to the ancient science, laws, and religion of Hindustan.

**PUNGENCY.** *s.* (from *pungent*.) 1. Power of pricking (*Arbutnot*). 2. Heat on the tongue; acridness. 3. Power to pierce the mind (*Hammond*). 4. Acrimoniousness; keenness (*Stillingfleet*).

**PURGENT.** *a.* (*purgens*, Latin.) 1. Pricking (*Pope*). 2. Sharp on the tongue; acrid (*Newton*). 3. Piercing; sharp (*Swift*). 4. Acrimonious; biting (*Dryden*).

**PUNICA.** Pomegranate tree. In botany, a genus of the class icosandria, order monogynia. Calyx superior, five-cleft; petalless;

pome many-celled, many-seeded. Two species, as follow :

1. *P. granatum*. Common pomegranate tree. Stem arboreous, eighteen or twenty feet high, armed with a few thorns; leaves lanceolate; flowers terminal, scarlet; fruit a pome-berry, covered with a hard coriaceous rind including a pulp. A native of the South of Europe. The bark, under the name of *granatum*, is used as an astringent in medicine. See *GRANATUM*.

2. *P. nana*. Dwarf pomegranate. Stem shrubby, five or six feet high; leaves linear; flower smaller than in the preceding; fruit not larger than a nutmeg, and of little flavour. A native of the Antilles.

Both sorts are cultivated, and may be best increased by layers: the former will bear the external atmosphere; the second requires the warmth of a greenhouse.

**PUNICEOUS.** *a.* (*punicus*, Latin.) Purple.

**PUNICUM BELLUM.** The first Punic war was undertaken by the Romans against Carthage, B. C. 264, and the ambition of Rome gave origin to it. For upwards of 240 years, the two nations had beheld with secret jealousy each other's power, when Sicily, an island of the highest consequence to the Carthaginians, as a commercial nation, became the seat of the first dissensions. From a private quarrel the war became general. The Romans obtained a victory in Sicily, but, as their enemies were masters at sea, the advantages they gained were inconsiderable. To make themselves equal to their adversaries, they aspired to the dominion of the sea, and in 60 days timber was cut down, and a fleet of 120 gallees completely manned and provisioned. The successes they met by sea were trivial. Duilius at last obtained a victory, and was the first Roman who ever received a triumph after a naval battle. The Carthaginians sued for peace, and the Romans, whom an unsuccessful descent upon Africa, under Regulus (see *REGULUS*), had rendered diffident, listened to the proposal, and the first Punic war was concluded B. C. 241. After this, the Carthaginians, who had lost, by the treaty of peace, the dominion of Sardinia and Sicily, made new conquests in Spain, and soon began to repair their losses by industry and labour. The Romans, not insensible of their successes in Spain, stipulated with them not to cross the Iberus, or molest the cities of the Saguntines. This was for some time observed, but, when Annibal succeeded to the command of the Carthaginian armies in Spain, he took Saguntum, whereupon complaints were carried by the Romans to Carthage, and war was determined upon, by the influence of Annibal in the Carthaginian senate. Without delay, B. C. 218, Annibal marched an army of 90,000 foot and 12,000 horse towards Italy. For the farther operations of this war, which was terminated 201 B. C. (see *ANNIBAL* and *SCIPIO*.) During the 50 years which followed the conclusion of the second Punic war, the Carthaginians were

employed in repairing their losses by unwearied application, but they found still in the Romans a jealous rival, and in Masinissa, the ally of Rome, an intriguing monarch. The king of Numidia made himself master of one of their provinces; but, as they were unable to make war without the consent of Rome, the Carthaginians sought relief by embassies, and made continual complaints in the Roman senate of the tyranny of Masinissa. Commissioners were appointed to examine the cause of their complaints; but the interest of the Carthaginians was neglected. Upon this the Carthaginians entered the field against the Numidians, and were defeated in a bloody battle by Masinissa, then 90 years old. By this bold measure they had broken the peace, and when the news of Masinissa's victory reached Italy, forces were sent to Sicily, and from thence ordered to pass into Africa. The Romans acted with the deepest policy: no declaration of war had been made, though hostilities appeared inevitable; and, on their arrival, demanded of the Carthaginians that they should deliver into their hands 300 hostages, all children of senators, and of the most noble and respectable families, all their ships, their arms, engines of war, with all their naval and military stores. To this rigid requisition the Carthaginians submissively agreed. But when they were told, that, to avoid hostilities, they must leave their ancient habitations, and retire into the inland parts of Africa, and found another city, at the distance of not less than ten miles from the sea, they determined to sacrifice their lives for the protection of the place which had given them birth. A regular siege then began, and two years were spent in useless operations, when Scipio, the descendant of the great Scipio, who finished the second Punic war, was sent to conduct the siege. The vigour of his operations soon baffled the efforts of the besieged. Despair and famine now raged in the city, and having at length carried the fortifications, he set fire to the houses. During 17 days, Carthage was in flames, 147 B. C. This remarkable event happened about the year of Rome 606, and the news of this victory caused the greatest rejoicings at Rome. Commissioners were appointed by the Roman senate, not only to raze the walls of Carthage, but even to demolish and burn the very materials with which they were made; and in a few days, that city, which had been once the seat of commerce, and one of the most powerful states of the world, left behind no traces of its splendour, its power, or even of its existence.

**PUNINESS.** *s.* (from *puny*.) Pettiness; smallness.

**TO PUNISH.** *v. a.* (*punio*, Latin.) 1. To chastise; to afflict with penalties or death for some crime (*Leviticus*). 2. To revenge a fault with pain or death.

**PUNISHABLE.** *a.* (*punissable*, Fr.; from *punish*.) Worthy of punishment; capable of punishment (*Taylor*).

**PUNISHABLENESS.** *s.* (from *punish*.)

*able*.) The quality of deserving or admitting punishment.

**PUNISHER.** *s.* (from *punish*.) One who inflicts pains for a crime (*Milton*).

**PUNISHMENT,** a penalty imposed upon the commission of some crime or offence against the laws.

It is essential to the nature of a law, that it import or decree a punishment to the transgressors thereof.

The forms and manners of punishment are various in various countries and ages, and for various crimes; as treason, felony, adultery, parricide, &c.

Among the Romans, the pecuniary punishments were the *multa* and *confisatio*. The corporal punishments were, *capitis diminutio*, *aquæ et ignis interdictio*, *proscriptio*, *deportatio*, *relegatio*, *furca*, *crux*, *carcer*, *culeus*, *equuleus*, *scalæ gemonæ*, *damnatio ad gladium*, *ad metallum*, *flagellatio*, *talio*, &c. which see described under their respective articles.

Among us the principal civil punishments are fines, imprisonments, the stocks, pillory, burning in the hand, whipping, ducking-stool, hanging, beheading, quartering, burning, transportation, &c.

The ecclesiastical punishments are censures, suspensions, deprivations, degradations, excommunications, anathemas, penances, &c. The military punishments are, being shot, running the gantelope, riding the wooden horse, the bilboes, &c. Among the Turks, &c. impaling, bastinadoes on the soles of the feet, &c. obtain.

The only two legitimate ends of human punishments seem to be the reformation of criminals, and the deterring of others from the commission of like crimes. For remarks on this subject, so important to all legislators, see the works of Montesquieu, Beccaria, Bentham, and Basil Montague.

The following return of commitments and trials in London and Middlesex, for five years, from 1805 to 1809, has been presented to the House of Commons, viz.

Committed. Indicted. Convicted.

|                |                |                |     |

**PUNITION.** *s.* (*punition*, French; *punitio*, Latin.) Punishment (*Ainsworth*).

**PUNITIVE.** *a.* (from *punio*, Lat.) Awarding or inflicting punishment (*Hammond*).

**PUNITORY.** *a.* (from *punio*, Latin.) Punishing; tending to punishment.

**PUNK.** *s.* A whore; a common prostitute (*Shakspeare*).

**PUNSTER.** *s.* (from *pun*.) A quibbler; a low wit who endeavours at reputation by double meaning (*Arbutnot*).

**To PUNT.** *v. a.* To play at basset and ombre (*Addison*).

**PUNTA DEL GUDA**, the capital of St. Michael, one of the Azores, with a strong castle. It is situate on the S. side, and contains 12,000 inhabitants. The streets are regular, and of convenient width; and the churches, religious houses, and public edifices may be deemed elegant. There is no harbour in the vicinity of the town, and vessels usually anchor at a distance from the shore in an open road. Lon. 25. 42 W. Lat. 37. 47 N.

**PUNY.** *a.* (*puis ne*, French.) 1. Young. 2. Inferiour; petty; of an under rate (*Shakspeare*).

**PUNY.** *s.* A young and unexperienced unseasoned wretch (*South*).

**To PUP.** *v. n.* (from *puppy*.) To bring forth whelps: used of a bitch bringing young.

**PUPIENUS** (Marcus Claudius Maximus), a man of an obscure family, who raised himself by his merit to the highest offices in the Roman armies. His father was a blacksmith. After the death of the Gordians, Pupienus was elected with Balbinus to the imperial throne, and immediately marched against the Maximini, but being informed that they had been sacrificed to the fury of their own soldiers, he retired to Rome. He soon after prepared to make war against the Persians, who insulted the majesty of Rome, but was prevented, and was massacred, A. D. 236, by the pretorian guards. Balbinus shared his fate. He was esteemed the constant friend of justice, moderation, and clemency.

**PUPIL.** *s.* (*pupillus*, Latin.) 1. A scholar; one under the care of a tutor (*Locke*). 2. A ward; one under the care of a guardian (*Dryden*).

**PUPIL.** (from *pupa*, a babe; because it reflects the diminished image of the person who looks upon it like a puppet.) The round opening in the middle of the iris, in which we see ourselves in the eye of another. See **EYE**.

**PUPILAGE.** *s.* (from *pupil*.) 1. State of being a scholar (*Locke*). 2. Wardship; minority (*Spenser*).

**PUPILARY.** *a.* (*pupillaris*, Latin.) Pertaining to a pupil or ward.

**PUPILLA.** See **PUPIL**.

**PUPPET.** *s.* (*poupée*, French; *pupus*, Latin.) 1. A small image moved by wire in a mock drama; a wooden tragedian (*Pope*). 2. A word of contempt (*Shakspeare*).

**PUPPETMAN.** *s.* (*puppet* and *man*.) Master of a puppetshow (*Swift*).

**PUPPETSHOW.** *s.* (*puppet* and *show*.) A

mock drama performed by wooden images moved by wire (*Swift*).

**PUPPY**. *s.* (*poupée*, French.) 1. A whelp; progeny of a bitch (*Gay*). 2. A name of contemptuous reproach to a man (*Shakspeare*).

**TO PUPPY**. *v. a.* (from the noun.) To bring whelps.

**PURBACH** (George), a German, eminent as a divine and philosopher. He made several astronomical observations, for the improvement of which he invented some instruments, and calculated useful tables. He translated Ptolemy's almagest, and died at Vienna 1462, aged 39. An interesting account of this eminent man is given in Dr. Hutton's Mathematical Dictionary.

**PURBECK** (Isle of), a rough and heathy tract in Dorsetshire, to the S. of Poole bay. It is insulated by the sea and rivers, and is famous for its stone quarries. The principal of these lie at its eastern extremity, near Swanage, whence the stone is exported. It is of the calcareous kind, but distinguished into numerous sorts, the finest of which deserve the name of marble, and are used for chimneypieces, hearths, &c. The coarser kinds are made use of in paving. Tobacco-pipe clay is dug up in several parts of this island, the finest near Corfe castle, of which much is exported, particularly for the Staffordshire potteries.

**PURBLIND**. *a.* (corrupted from *poreblind*.) Nearsighted; shortsighted (*Shakspeare*).

**PURBLINDNESS**. *s.* Shortness of sight.

**PURCELL** (Henry), a celebrated musical composer, born in 1658. At 18 he was organist of Westminster, and in 1682 was made one of the organists of the chapel royal. He published some sonatas and anthems, and divided his services between the church and the theatre. Dryden, some of whose poetry he set to music, has highly complimented his powers. He died of a consumptive disorder, 1695. His works were published by subscription, under the title of Orpheus Britannicus, 1698. His brother Daniel, a famous punster, was organist of Magdalen college, Oxford, and of St. Andrew's, Holborn.

**PURCHASABLE**. *a.* (from *purchase*.) That may be purchased, bought, or obtained (*Locke*).

**TO PURCHASE**. *v. a.* (*purchasser*, Fr.) 1. To acquire, not inherit. 2. To buy for a price (*Shakspeare*). 3. To obtain at any expence, as of labour or danger (*Milton*). 4. To expiate or recompense by a fine or forfeit (*Shaksp.*).

**PURCHASE**. *s.* (*pourchas*, old French.) 1. Any thing bought or obtained for a price (*Locke*). 2. Any thing of which possession is taken any other way than by inheritance (*Shakspeare*).

**PURCHASER**. *s.* (from *purchase*.) A buyer; one that gains any thing for a price (*Addison*).

**PURE**. *a.* (*pur*, *pure*, French; *purus*, Lat.) 1. Clear; not dirty; not muddy (*Sidney*). 2. Not filthy; not sullied (*Proverbs*). 3. Unmingled; not altered by mixtures (*Tay.*). 4. Genuine; real; unadulterated (*James*). 5.

Not connected with any thing extrinsic: as, pure mathematics (*Watts*). 6. Free; clear (*Philips*). 7. Free from guilt; guiltless; innocent (*Milton*). 8. Incorrupt; not vitiated by any bad practice or opinion (*Ticket*). 9. Not vitiated with corrupt modes of speech (*Ascham*). 10. Mere: as, a pure villain (*Clarendon*). 11. Chaste; modest: as, a pure virgin.

**PURELY**. *ad.* (from *pure*.) 1. In a pure manner; not dirtily; not with mixture (*Isa.*). 2. Innocently; without guilt. 3. Merely; completely; totally (*Clarendon*).

**PURENESS**. *s.* (from *pure*.) 1. Clearness; freedom from extraneous or foul admixtures (*Temple*). 2. Simplicity; exemption from composition (*Dryden*). 3. Innocence; freedom from guilt (*Common Prayer*). 4. Freedom from vitious modes of speech (*Ascham*).

**PURFILE**. *s.* (*pourfilée*, French.) A sort of ancient trimming for women's gowns (*Bailey*).

**TO PURFILE**. *v. a.* (*pourfiler*, French.) To decorate with a wrought or flowered border (*Spenser*).

**PURFILE**. *s.* (*pourfilée*, Fr.) A border of embroidery.

**PURGATION**. *s.* (*purgation*, French.) 1. The act of cleansing or purifying from vitious mixtures (*Burnet*). 2. The act of cleansing the body by downward evacuation (*Bacon*). 3. The act of clearing from imputation of guilt.

**PURGATIVE**. *a.* (*purgatif*, Fr. *purgativus*, Lat.) Cathartic; having the power to cause evacuation downward (*Bacon*).

**PURGATORY**, a place in which the just, who depart out of this life, are supposed to expiate certain offences which do not merit eternal damnation. Broughton has endeavoured to prove that this notion has been held by Pagans, Jews, and Mahometans, as well as by Christians; and that in the days of the Macca-bees the Jews believed that sin might be expiated by sacrifice after the death of the sinner, cannot be questioned.

Much abuse has been poured upon the church of Rome for her doctrine of purgatory, and many false representations have been made of the doctrine itself. The following view of it is taken from a work which is considered as a standard by the British Catholics. 1. Every sin, how slight soever, though no more than an idle word, as it is an offence to God, deserves punishment from him, and will be punished by him hereafter, if not cancelled by repentance here. 2. Such small sins do not deserve eternal punishment. 3. Few depart this life so pure as to be totally exempt from spots of this nature, and from every kind of debt due to God's justice. 4. Therefore few will escape without suffering something from his justice for such debts as they have carried with them out of this world; according to that rule of divine justice, by which he treats every soul hereafter according to its works, and according to the state in which he finds it in death. From these propositions, which the Papist con-

siders as so many self-evident truths, he infers that there must be some third place of punishment; for, since the infinite goodness of God can admit nothing into heaven which is not clean and pure from all sin both great and small; and his infinite justice can permit none to receive the reward of bliss, who as yet are not out of debt, but have something in justice to suffer; there must of necessity be some place or state, where souls departing this life, pardoned as to the eternal guilt or pain, yet obnoxious to some temporal penalty, or with the guilt of some venial faults, are purged and purified before their admittance into heaven. And this is what he is taught concerning purgatory. Which, though he knows not where it is, of what nature the pains are, or how long each soul is detained there; yet he believes, that those that are in this place, being the living members of Jesus Christ, are relieved by the prayers of their fellow members here on earth, as also by alms and masses offered up to God for their souls. And as for such as have no relations or friends to pray for them, or give alms, or procure masses for their relief; they are not neglected by the church, which makes a general commemoration of all the faithful departed in every mass, and in every one of the canonical hours of the divine office.

Such is the Popish doctrine of purgatory, which is built chiefly upon 2 Macc. xii. 43, 44, 45; St. Matth. xii. 31, 32; and 1 Cor. iii. 15. By Protestants the books of Maccabees are not acknowledged to be inspired scripture; but if they were, the texts referred to would rather prove that there is no such place as purgatory, since Judas did not expect the souls departed to reap any benefit from his sin-offering till the resurrection. Our Saviour, in St. Luke, speaks of remission in this world and in the world to come; but surely neither of these is purgatory. The world to come is the state after the resurrection, and the remission spoken of is the sentence of absolution to be pronounced on the penitent from the seat of general judgment.

**TO PURGE.** *v. a.* (*purgo*, Latin.) 1. To cleanse; to clear (*Bacon*). 2. To clear from impurities (*Woodward*). 3. To clear from guilt (*Hebrews*). 4. To clear from imputation of guilt (*Shakspeare*). 5. To sweep or put away impurities (*Decay of Piety*). 6. To evacuate the body by stool (*Camden*). 7. To clarify; to defecate.

**TO PURGE.** *v. n.* 1. To grow pure by clarification. 2. To have frequent stools.

**PURGE.** *s.* A cathartic medicine; a medicine that evacuates the body by stool (*Arbuthnot*).

**PURGER.** *s.* (from *purge*.) 1. One who clears away any thing noxious (*Shakspeare*). 2. Purge; cathartic (*Bacon*).

**PURGING;** an evacuation procured from the intestines by means of cathartic substances.—It is often had recourse to both as a preventive and as a cure for diseases actually existing. As a preventive it is also frequently employed in veterinary practice. So serviceable indeed is it to

cattle of various kinds and especially to horses, that a season for purging is deemed almost as necessary as a season for work. Mr. Clark of Edinburgh, in his Treatise on the prevention of diseases in horses, has well described the principles on which purgative medicines should be exhibited. "The action of purging," he observes, "consists in irritating the sensible fibres of the stomach and intestines, by which means, not only the peristaltic motions of the latter are considerably quickened, but also the secretions of mucous and lymphatic juices, and vapours, which ooze every where into the cavities of the intestines, are increased, together with unusual quantities of pancreatic juice and bile from their several sources; hence it will be obvious, how great a quantity of the soundest humours, or even the chyle that is derived from the food, before it is mixed with the blood, may be carried off by purging medicines, and how much the whole mass of fluids, in general, may be decreased and drawn off.

"Since, therefore, purging is occasioned by giving such medicines as are found, by their irritating quality, to stimulate the coats of the stomach and guts, and, at the same time, quicken the peristaltic motion of the latter, so as to cause them to shake or throw off their contents by stool, it would appear, that the different kinds of purging medicines differ only in degrees of strength, and that they operate no otherwise upon the different humours of the body than as they stimulate the first passages more or less, and hence cause a greater or lesser evacuation by stool. So that, by this operation, we only lessen the quantity of the fluids, and clear or scour the first passages from any offending matters that may be lodged there. From hence it may likewise be inferred, that there is no such thing as elective purgation, that is, by giving certain medicines, we drain off this or that particular humour from the body. This may be further illustrated in the following case or example. When a horse, that has swelled legs or greasy heels, gets purging medicines, they do not act immediately on the fluids contained in the legs, by carrying them off only, they act by revulsion, that is, by drawing away the fluids, &c. from the stomach and intestines; those that are in the legs are, at the same time, absorbed or drawn away from the extremities by the absorbent vessels, to supply the want in the former; and hence the swelling in the legs, &c. subsides."

Our author, in the introductory part of his chapter, having taken notice of the great length of the intestines in the horse, says, "This, together with the horizontal or prone position of the body of a horse, is unfavourable to the operation of purging medicines, which, on that account, remain in the intestines a considerable time before they operate, being from 18 to 28 or 30 hours, according to the state of the bowels at the time, and, in some constitutions, even longer. In these cases, it is not advisable to give any medicines in order to quicken or hasten their operation; walking exercise, but not long continued at a time; together with plenty of warm water, if the horse will drink, is the best and safest means to forward their operation. At the same time, it will be necessary to notice whether the horse stales more than usual, as purging medicines are found sometimes to operate in that way, without any considerable evacuation by dung."

A proper caution in giving purging balls, is, "that the operator should push the ball over the roof of the tongue, and that he be certain of the

## P U R G I N G.

ball's being swallowed entire, and not broken or thrown out of the mouth. Mistakes of this kind have frequently occurred: when the ball breaks, one-half, perhaps, is only swallowed, the other drops out of the mouth, or it may happen that the whole ball drops out unperceived. In these cases, it is concluded, from the purge not operating in due time, that it has been too weak, and therefore the next dose is made considerably stronger, and hence a superpurgation ensues, attended with great sickness, loss of strength, and other bad consequences. Therefore, when purging balls are given to horses, the head should be kept up, and care taken that the ball passes down the gullet, which may easily be discovered sliding down from the outside; but, if any doubt remains of its being swallowed, a little water may be given the horse to drink, and one gulp or two will put it out of all doubt."

In adverting to the common practice of giving purging balls upon an empty stomach, our author observes that this, in some constitutions, occasions great sickness, faintness, griping, &c. long before they begin to operate. To prevent which he recommends a mash of bran to be given about an hour or more before the ball, which contributes to the effects of the purge, and causes it to operate in the most gentle and easy manner.

"Another error," continues he, "which many people fall into is, that although a purge operates very well, yet, if the horse is not very sick during its operation, they conclude that it will not be of any benefit to him; and they therefore give the next purge made a good deal stronger, in order, as they say, to stir up the humours; for they conclude that the sicker a horse is under this operation, the humours are the more stirred up, and the easier carried off by the purge, without considering the danger to which they expose the animal.

"When purging medicines are intended to be given to horses, it is necessary that they should be kept quiet and at rest for some time before, that is, from any very violent exercise; and the same rule should be observed for some days after their operation is over, walking exercise only excepted. It is owing to the want of these, and such-like precautions, already mentioned, that so many accidents happen daily in the purging of horses."

Having proceeded thus far, our author next considers that part of the subject which relates to the practice of purging horses, by way of preparing them for running, hunting, &c. "It must be acknowledged," says he, "there is a difficulty in combating a practice which too generally prevails, although there are a number of facts which will serve to demonstrate, that the purging of horses indiscriminately is not necessary in order to prepare them for these active exercises. On the contrary, it must, and indeed is, in many cases, exceedingly hurtful, on account of the too frequent repetition of them, together with the too short intervals generally allowed between each purgation.

"It is well known, that horses, by good feeding, regular exercise, &c. may be brought to perform the most active exercises; and that many instances daily occur of horses both running and hunting, without undergoing any previous preparation by purging medicines; and it is likewise well known, that, even when purging medicines are given, still regular exercise is found to be absolutely necessary, in order to habituate the horse to this kind of active labour.

"Post horses likewise furnish a further proof of what has been advanced. It is well known how they can be brought to travel very long stages, and with great speed, without any preparation, farther than good feeding, and inuring them by degrees to this violent labour." Bracken, who understood this subject well, and who was likewise a great sportsman, took great pains, in hopes of exploding this absurdity. He has given it as his opinion, that in most cases, good feeding, regular exercise, &c. will make a horse fit to start for a plate, without the use of many purgative compositions to carry off grease, and mend his wind; for the jockeys, he says, are too fond of giving purges to horses, by which they certainly weaken their constitutions, by causing the fibres of the stomach and guts to become lax and flabby. To strengthen this assertion, he mentions the case of a mare of his own, that he had run for six years, having in that time given her only two purges; "neither," says he, "had she an ounce of any kind of medicine during that time, except every morning, and mostly every evening, a bout the bigness of a pigeon's egg of my cordial ball; and, I fancy, she performed as well as most of her neighbours, for she won eight plates out of nine, and four out of six, every year."

Mr. Clark next speaks of the vulgar opinion of humours falling down into this or that particular part of the body, if a horse be not properly purged, &c. before he undertakes any active exercises, such as racing, hunting, &c.

"It may be of use to the young practitioner," he says, "to explain what is meant by the phrase of humours falling down; but at the same time, I must inform him, that this phrase is so generally in use, that, when a horse's eyes are affected, the humours are said to fall down into them, although they are situated nearly in the most elevated part of the body. But to explain their falling down to the extremities, I shall take a case that frequently occurs. When a horse, that is in the highest state of health, but too fat and full of juices, &c. and accustomed to stand much at rest, is suddenly put to violent or long-continued exercises, his legs will be apt to swell soon after; they will perhaps continue in that state for some time; they may at last break out in running sores about the heels, and form cracks, &c.; when in this situation, it is said, that the humours have fallen down to the legs. Here a question naturally occurs, Where were these humours before the horse got this severe exercise, and how came they to fall down on this occasion only?"

Unless a horse has been gradually habituated to exercise previous to his undergoing that which is violent or long continued, his vessels will be too full of fluids, and these, especially the finer capillaries, from the force and rapidity of the circulation during the exercise, will admit the grosser fluids that do not usually circulate in them. They likewise are liable, in these cases, to be ruptured: hence the fluids they contain escape into the cellular membrane, where they stagnate, and, being then out of the course of circulation, occasion a swelling. "If this happens in the legs," says Mr. Clark, "as they are the most depending parts of the body, the humours are then said to have fallen down, the swelling causes a distension of the skin, &c.; the cuticular pores are then enlarged, and admit through them the thinner parts of the fluids to the outward surface of the skin, which, on being exposed to the external air, are then changed in their quality, and acquire, according to circum-

## PURGING.

stances; either a soapy, clammy, or greasy nature, or else a sharp fetid ichorous quality, that erodes the skin, and, by lodging there, form small ulcers.

"It ought always to be remembered, that great evacuations weaken an animal body, and, if they are repeated too frequently, and too close upon one another, without allowing a proper interval between each, or, if they are carried to excess, which is sometimes the case, the weakness in the animal system is thereby increased, the powers of life are quite overcome, and death follows, of course."

The author however would not be understood to mean, that purging medicines are never to be used on these occasions. On the contrary, he expresses himself fully sensible of their good effects, when judiciously administered, the horse being at the same time properly managed during their operation. "But," says he, "I do not approve of repeating purge after purge, merely because this or that horse is to run or hunt, without first considering whether the animal be fat or lean, or whether he has been kept at hard meat, with proper exercise, or whether he has run a considerable time, or late in the season, at grass; all these, and a number of other circumstances necessary to be attended to, ought to be duly weighed and maturely considered, before any purging medicines are administered: for example, if a horse has run long at grass, and is of a plethoric or full habit of body, evacuations by purging, and diuretic medicines to a certain degree, are necessary, together with length of time, good feeding, and regular exercise, to bring his body into that proper habit to enable him to perform with freedom such active exercises. But if a horse is of a lean, low, or dry habit of body, whether it may proceed from the want of proper food, from fatigue, or any other cause, are we to reduce him still lower by repeated evacuations of any kind? There is such an inconsistency in this practice, that it would not even deserve to be noticed, were it not too much practised every day; for, with some people, it is no matter of consideration with them what state of body a horse may be in, that is, whether he be of a fat, or full, or lean, dry habit of body; still he is said to be full of humours, and which must be purged off before he is fit for hunting or running, &c. Horses, in the latter situation, require only good feeding, and regular exercise, to strengthen and improve their constitutions, which cannot fail of taking place, if the viscera are sound, and the horse otherwise in a healthy state. And, even although a horse should be a little inclined to the full, or what is called the plethoric habit, yet, from the use of diuretic medicines, which are commonly given on these occasions, together with regular airings and proper exercise, good feeding, dressing, &c. he may be brought into that proper habit of body which will enable him to perform the most violent labour with the greatest ease to himself, and without any bad consequences."

After a variety of other arguments calculated to show, that repeated evacuations, of any kind, are not necessary for horses in training either for the turf or the field, Mr. Clark suggests, that if those horses that are intended for hunting were only allowed the spring-grass, and taken up about the middle or towards the latter end of June, before the grass becomes too rank, although it may be

rather inconvenient to have them in the house at that season, yet the owner would find his account in it. The allowance of oats, he observes, must be but small for some little time, but it might be increased, together with the horse's exercise, as the hunting season approaches. "Running horses might be treated in the same manner, according to the season in which they are to run, allowing both a greater length of time in the habitual practice of these exercises, together with proper feeding, dressing, &c. This treatment, together with the use of those alterative and diuretic medicines, which are usually given on these occasions, would render horses much stronger and fitter for these active exercises, without wearing out their constitutions by the repeated use of purging medicines."

Mr. Clark next adverts to the use of purging, as a remedy in diseases. "The substances," says he, "that are used for purging or emptying the alimentary canal, may be distinguished into two kinds, the lenient, which open the belly gently; and the drastic, which purge more briskly. The lenient ought always to be preferred when there appears any unusual commotion in the vascular system, which may easily be known by the quickness of the pulse, &c.; for, although purging medicines increase the motion of the pulse during their operation, yet they afterwards abate or lessen the motion of the blood, by drawing off a considerable quantity of the animal fluids by stool; they likewise clear the intestines of sharp stimulating matters or worms, which occasion an unusual degree of irritation in the system; they likewise may be given with different intentions, as circumstances may require, in small doses, to keep the body open, and prevent an accumulation of feces or dung in the intestines, which happens in diseases. In cases of frequent returns of the gripes or cholice, but not during the fit, lest the guts should then be inflamed, they should therefore be given in the intervals, in order to prevent the return of the complaint."

"But, in cases where it is thought necessary to clear the intestines thoroughly, in strong robust horses, the drastic purges may be given, provided there is no great commotion in the circulation of the blood at the time. Purging medicines are of great service in cases where the intestines appear to be loaded with viscid or thick slime, or when it appears, by long-continued costiveness, that the peristaltic motion of the intestines is in some degree suspended; in gross habits, especially where there is any tendency to swellings in the legs, attended with running sores, &c.; in dropsical swellings in any part of the body; in diseases of the head, rheums, or defluxions about the eyes; in rheumatic lameness, when the pains seem to move from one limb to another; in the jaundice; in obstinate coughs, especially when the horse is of a full habit of body; in most cutaneous diseases, or when a number of small pimples or lumps arise on the skin, and suddenly disappear again, or when the lumps discharge a sharp fluid of an ichorous quality; in plethoric or full habits, when the horse is intended for violent or active exercises, as running, hunting, &c.; in cases where it is judged necessary to lessen the general mass of fluids, or to divert them from flowing to any particular place in too great a quantity, as in inflammations of the lungs; in this last case, liquid purges are most proper, as they operate more expeditiously, in

very delicate constitutions, rhubarb should constitute the greatest part of their purging medicines; they are likewise most proper in cases of want of appetite: no doubt there may be other cases where purging medicines may be necessary; but these must depend on the discretion and judgment of the prescriber.

"On the other hand, it will be prudent to avoid giving purging medicines during extreme cold weather; likewise in all feverish complaints, when the pulse beats strong and quick, till such time as these symptoms are considerably abated; in all cases of extreme weakness, whether arising from fatigue or long-continued diseases; in all lean dry habits, unless there is reason to apprehend it proceeds from worms; in cases of very obstinate costiveness, till such time as that complaint is in some degree removed by clysters, soft feeding, &c.; in cases when a horse labours under any violent acute complaint; in diarrhoea or looseness. Aloetic purges, or those in which aloes enter into the composition, are to be avoided likewise in severe cholics or griping pains, although liquid purges, that are quicker in their operation, and less irritating, may be given with safety in the intervals, when it is observed that horses are subject to frequent attacks of this complaint.

"Previous to the giving of purging medicines to horses, especially to those that have been kept on hard meat, it will be prudent to keep them from all violent exercises for some days before the purge is given. If they are fat, and of a full habit, it will be necessary to draw some blood, to lower their feeding, and to give them that which is soft and relaxing, as boiled barley, mashies of bran, malt, &c. When horses are to be purged at grass, no preparation is necessary, farther than in plethoric or full habits, to treat them as above, observing, at the same time, that they be not costive, as this frequently happens although feeding on grass; in that case, they are to be taken into the stable, and treated as if they had been on hard feeding.

"In giving purging medicines to horses, it will always be most prudent to begin at first by giving mild lenient purges, in order to find out the strength of the constitution, &c. as very strong robust horses, to appearance, are sometimes easier purged than those of a more delicate make; and it frequently happens, that the same horse is easier purged at one time than at another, according to the state of the stomach and the intestines at the time the purge is given.

"Mild purges are therefore much safer at all times, and of more benefit to the constitution, than too strong ones; for the latter cause too great an irritation of the stomach and bowels; whence follow griping pains, great sickness, &c. and sometimes inflammation of the intestines; they likewise may occasion a superpurgation, by which the bowels are so much weakened, that they never afterwards recover their former tone; and hence follow loss of appetite, general weakness, and, perhaps, an habitual diarrhoea or looseness."

On the subject of mild purging, it may be proper here to advert to a practice very judiciously used by Mr. Professor Coleman, and recommended in his lectures. In the opinion of that gentleman there is no substance in the *materia medica* more appropriately used for purging horses than aloes, and its operation may be reduced to almost any degree of mildness by its administration in small and repeated doses: for instance one drachm con-

tinued at proper intervals, till its effects begin to take place, but not afterwards.

**PURGING FLAX.** See **LINUM CATHARTICUM**.

**PURGING NUT.** See **RICINUS MAJOR**, and **JATROPHA**.

**PURIFICATION.** *s.* (*putrificatio*, Lat.)

1. The act of making pure (*Boyle*). 2. The act of cleansing from guilt or pollution (*Taylor*).

**PURIFICATION**, in matters of religion, denotes an offering made the priest by women rising out of child-bed, before they are re-admitted into the church.

By the law of Moses, a woman, after bringing forth a male child, was unclean forty days; after a female eighty days; during which time, she was not to touch any thing holy, nor to go near the temple, but was to continue within doors, separate from all company, and commerce of others.

This term expired, she was to present herself at the temple, and at the door of the tabernacle, to offer a lamb, as an holocaust, and a pigeon or turtle; which the priest taking, offered to God, and prayed for her, that she might be purified.

This ceremony, which consisted of two things, an holocaust, and a sacrifice of expiation, was called טוהר טהרה, *purificatio*, *pur-gatio*.

The holy Virgin, though, according to the fathers, exempt from the terms of the law, yet complied therewith, and, at the time prescribed, went to the temple, and accomplished the law; in commemoration whereof, the church yearly solemnizes the feast of the purification of the Virgin, on the second of February; called also the feast of Candlemas.

**PURIFICATIVE.** *PU'RIFICATORY.* *a.* (from *purify*.) Having power or tendency to make pure.

**PURIFIER.** *s.* (from *purify*.) Cleanser; refiner (*Malachi*).

To **PURIFY.** *v. a.* (*purifier*, French; *purifico*, Latin.) 1. To make pure. 2. To free from any extraneous admixture (*Dryden*). 3. To make clear (*Sidney*). 4. To free from guilt or corruption (*South*). 5. To free from pollution, as by lustration (*Job*). 6. To clear from barbarisms or improprieties (*Sprat*).

To **PURIFY.** *v. n.* To grow pure (*Burnet*).

**PURIST.** *s.* (*puriste*, French.) One superstitiously nice in the use of words.

**PURITANS** is a term anciently used for the Calvinists of Great Britain, from their professing to follow the pure word of God, in opposition to all traditions, human constitutions, and other authorities.

The separation, whence this distinguishing appellation took its rise, commenced on the following occasion. Upon the accession of queen Mary, it is well known that popery revived in this kingdom; the statutes of king Edward were repealed, and the penal laws against heretics were put in execution against the reformers. Many suffered at home; and others escaped the fury of persecution by seeking refuge in foreign countries. Some went into France and Flanders; some to Geneva

## PURITANS.

and others into those parts of Germany and Switzerland, where the reformation had taken place, and where the magistrates received them with great humanity, and allowed them places for public worship. The exiles were most numerous at Francfort; and there that contest and division began, which gave rise to the Puritans, and to that separation from the church of England, which continues to this day. In the year 1554, some of the English fugitives settled in this city; and agreed to conduct their worship, without answering aloud after the minister, and without using the liturgy and surplice; to begin the public service with a general confession of sins, then to sing a psalm, after which the minister prayed for the divine assistance, and next proceeded to the sermon; after sermon, a general prayer for all estates, and particularly for England, at the end of which was subjoined the Lord's prayer, and a rehearsal of the articles of belief; then the people were to sing another psalm, and the minister to dismiss them with a blessing. Such was the order which they had unanimously adopted; and having chosen a minister and deacons, they invited their dispersed brethren to join with them. In the year 1556, Dr. Cox, afterwards bishop of Ely, came to settle at Francfort with several of his friends; who, interrupting the public service by answering aloud after the minister, and reading the whole litany, in violation of the agreement upon which the congregation was formed, overpowered the first settlers; and obtaining leave of the magistrates for the free use of king Edward's service book, performed divine worship according to the rites that had been authorised by that prince; while others, who preferred the Genevan method of worship, as more pure and simple, left the city of Francfort, and removed to Basil and Geneva. Thus commenced the distinction of Puritans and Conformists, by which the two parties were afterwards known. The former were called Conformists, on account of their compliance with the ecclesiastical laws enacted by Edward VI. and the denominations of Nonconformists and Puritans were given to the latter, from their insisting upon a form of worship, more exempt from superstition, and of a purer kind than the liturgy of Edward seemed to them to be. Upon the accession of queen Elizabeth, the exiles returned to England, where each party strove to advance the reformation according to their own standard. The queen, with those who had weathered the storm at home, were only for restoring king Edward's liturgy; but the majority of the exiles were for the worship and discipline of the foreign churches, and refused to comply with the old establishment, declaiming loudly against the popish habits and ceremonies. However, the queen's party prevailed; and in 1559 a committee of divines was appointed to review king Edward's liturgy, who were instructed to strike out all offensive passages against the pope, and to make people easy about the belief of the corporal presence of Christ in the sacrament. But no alterations were made in favour of those who now began to be called Puritans, from their attempting a purer form of worship and discipline than had yet been established; and whose sentiments in many points were agreeable to those maintained by John Wickliffe, the first reformer. For they agreed with him in opinion, that in the sacrament of orders there ought to be but two degrees, presbyters or bishops, and deacons; that all human traditions are superfluous and sinful; that we

must practise and teach only the laws of Christ; that mystical and significant ceremonies in religious worship are unlawful; and that to restrain men to a prescribed form of prayer is contrary to the liberty granted them by God. The old festivals, with their eves and the popish habits, were continued as they were in the second year of king Edward VI. In 1558 the act of supremacy was passed, in which there is a remarkable clause, that gave rise to the court of high commission, which proved afterwards so oppressive; and in 1559 was passed an act for the uniformity of common prayer, and service in the church, and administration of the sacraments. The Puritans remonstrated against these proceedings, and complained, that the gross superstitions of popery, which they had looked upon as abrogated and abolished, were now revived, and even imposed by authority. Some required nothing less than that the church of England should be exactly modelled after that of Geneva; others only desired liberty of conscience, with the privilege of celebrating divine worship in their own way; but neither party obtained the object of their wishes. The queen, intent upon the suppression of this troublesome sect (as she was used to call it), permitted its enemies to employ for that purpose all the resources of artifice, and all the severity of the laws. The court reformers pleaded, that every prince had authority to correct all abuses of doctrine and worship within his own territories; the Puritans, on the other hand, whilst they disowned all foreign authority and jurisdiction over the church, could not admit of that extensive power which the crown claimed by the supremacy; apprehending it unreasonable, that the religion of a whole nation should be at the disposal of a single lay person. However, they took the oath, with the queen's explication in her injunctions, as restoring her majesty only to the ancient and natural rights of sovereign princes, over their subjects.

Farther, the court reformers allowed, that the church of Rome was a true church, though corrupt in some points of doctrine and government; that all her ministrations were valid, and that the pope was a true bishop of Rome, though not of the universal church. But the Puritans affirmed the pope to be antichrist, the church of Rome to be no true church, and all her ministrations to be superstitious and idolatrous; they renounced her communion, and durst not suspend the validity of their ordinations upon an uninterrupted line of succession from the apostles through her hands. Moreover it was agreed by all, that the holy scriptures were a perfect rule of faith; but the bishops and court reformers did not allow them to be the standard of discipline or church government; affirming that our Saviour and his apostles left it to the discretion of the civil magistrate, in those places where Christianity should obtain, to accommodate the government of the church to the policy of the state. But the Puritans apprehended the holy scriptures to be a standard of church discipline as well as of doctrine; at least that nothing should be imposed as necessary but what was expressly contained in, or derived from them by necessary consequence; and, besides, they maintained that the discretionary power was not lodged with the civil magistrate, but with the spiritual officers of the church. Farther, the court reformers maintained, that the practice of the primitive church for the first four or five centuries was a proper standard of church govern-

## PURITANS.

ment and discipline, and in some respects a better than that of the apostles, which (according to them) was only accommodated to the infant state of the church while it was under persecution, whereas theirs was suited to the grandeur of a national establishment. Whereas the Puritans were for adhering to the Bible in the main principles of church government, and for admitting no church officers or ordinances, but such as are herein mentioned; and they apprehended, that the apostles, in establishing the first Christian church on the aristocratical plan then observed in the Jewish sanhedrim, designed it as an unchangeable model to be followed in all times and places. The court reformers also maintained, that things indifferent in their own nature, which are neither forbidden nor commanded in the holy scriptures, such as rites, ceremonies, habits, &c. might be settled, determined, and made necessary by the command of the civil magistrate, and that in such cases it was the indispensable duty of all subjects to observe them. But the Puritans insisted, that those things which Christ had left indifferent ought not to be made necessary by any human laws, and that such rites and ceremonies as had been abused to idolatry, and had a manifest tendency to lead men back to popery and superstition, were no longer indifferent, but to be rejected as unlawful. Nevertheless, both parties agreed too well in asserting the necessity of an uniformity of public worship, and of calling in the sword of the magistrate for the support and defence of their several principles; which they made an ill use of in their turns, as they could grasp the power into their hands. The standard of uniformity, according to the bishops, was the queen's supremacy, and the law of the land; according to the Puritans, the decrees of provincial and national synods, allowed and enforced by the civil magistrate; but neither party were for admitting that liberty of conscience, and freedom of profession, which is every man's right, as far as is consistent with the peace of the government under which he lives.

In the year 1564, upon a report that the habits, enjoined on the clergy, were generally neglected, and also of inattention to other imposed forms, the queen directed the ecclesiastical commissioners to consult some proper methods to reduce them to an exact uniformity; upon which they agreed on certain advertisements (as they were called) partly for due order in preaching and administering the sacraments, and partly for the apparel of ecclesiastical persons. To these advertisements certain protestations were annexed, to be made, promised, and subscribed by such as should hereafter be admitted to any office or cure in the church. The queen, though she would give no authority to the advertisements, which had occasioned much remonstrance and complaint, issued out a proclamation in 1565, peremptorily requiring uniformity in the habits, upon pain of prohibition from preaching, and deprivation. Parker, the archbishop of Canterbury, was violent and unrelenting; and by various methods of severity harassed, silenced, and deprived many of those who scrupled the use of the habits. The suspended ministers, finding that renewed applications to the queen and her commissioners were ineffectual, published in 1566 a small treatise in vindication of their conduct; in which they allege, that neither the prophets of the Old Testament, nor the apostles in the New, were distinguished by their garments; that a distinction of garments in the Chris-

tian church did not generally obtain till long after the rising of antichrist; that the garments against which they objected had been abused to idolatry, sorcery, and all kinds of conjurations; that they were an offence to weak Christians, an encouragement to ignorant and obstinate papists, and the use of them an affectation of returning to their communion; that at best they were only human appointments, subject to the apostle's reproof; Col. ii. 20—22. that allowing them to be indifferent (which they did not grant) yet they ought not to be imposed, because it was an infringement of the liberty with which Christ had made them free; and finally they urged the suffrage of foreign divines, who all condemned the habits, though they were not willing to hazard the reformation in its infancy, on account of them.

If, at this time, the habits and a few ceremonies had been left indifferent, both ministers and people would have acquiesced; but it was the compelling of these things by law that made them separate from the established church. Accordingly, in 1566, they came to a resolution, alleging it to be their duty, in their present circumstances, to break off from the public churches, and to assemble, as they had opportunity, in private houses, or elsewhere, to worship God in a manner that might not offend against the light of their consciences; and it was debated among them, whether they should use as much of the common prayer and service of the church as was not offensive, or resolve at once, since they were cut off from the church of England, to set up the purest and best form of worship, most consonant to the holy scriptures, and to the practice of the foreign reformers. The latter of these measures was concluded upon; and accordingly they laid aside the English liturgy, and made use of the Geneva service book. However, it is necessary to observe, that though all the Puritans of these times would have remained in the church, if they might have been indulged in the habits and a few ceremonies, yet they were far from being satisfied with the hierarchy. They had other objections besides those for which they were deprived; of which we shall here subjoin a summary. They complained of the bishops affecting to be thought a superior order to presbyters, and claiming the sole right of ordination, and the use of the keys; and assuming, in connection with their office, temporal dignities, titles, and employments. As long, however, as the English bishops pretended to derive their dignity and authority from no other source than the laws of their country, and pleaded a right, merely human, to the rank they held in church and state, the controversy was carried on without excessive animosity and zeal; but the flame broke out with redoubled fury in the year 1588, when Bancroft, afterwards archbishop of Canterbury, ventured to assert that the order of bishops was superior to the body of presbyters, not in consequence of any human institution, but *jure divino*, or by the express appointment of God himself. Farther, the Puritans excepted against the titles and offices of archdeacons, deans, chapters, and other officials, belonging to cathedrals, as having no foundation in scripture, or primitive antiquity, and intrenching upon the privileges of the presbyters in the several dioceses. They complained of the exorbitant power and jurisdiction of the bishops and their chancellors in their spiritual courts, as derived from the canon law of the pope, and not from the word of God, or the statute law of the land. They lamented

## PURITANS.

the want of a godly discipline, and were uneasy at the promiscuous and general access of all persons to the Lord's table. Though they did not dispute the lawfulness of set forms of prayer, provided a due liberty was allowed for prayers of their own composure before and after sermon, yet they disliked the frequent repetition of the Lord's prayer in the liturgy, the interruption of the prayers by the frequent responses of the people, some passages in the office of marriage, as With my body I thee worship, and in that of burial, as In sure and certain hope of the resurrection to eternal life, pronounced over the worst of men, if not excommunicated, &c. They also objected against the reading of the apocryphal books in the church, while some parts of canonical scripture were omitted; and though they did not dislike the homilies, they thought that no man should be ordained a minister in the church, who was not capable of preaching and expounding the holy scriptures. They disapproved of several of the church festivals or holidays, as having no foundation in scripture, or primitive antiquity; and they disallowed of the cathedral mode of worship; nor did they approve of musical instruments in the church service. Finally, they scrupled conformity to certain rites and ceremonies, which were enjoined by the rubric, or the queen's injunctions; as the sign of the cross in baptism, baptism by midwives or other women, in cases of sickness, and the mode of churching women; the use of god fathers and god-mothers, to the exclusion of parents from being sureties for the education of their own children; the custom of confirming children, as soon as they could repeat the Lord's prayer and their catechism, by which they had a right to come to the sacrament, without any other qualification, and the imposition of hands, as a sign of the divine favour, which seemed to them to imply a sacramental efficacy in this ceremony; kneeling at the sacrament of the Lord's supper, whilst they considered that Christ gave it to his disciples rather in a posture of feasting than of adoration; that it had no foundation in antiquity; that it had been grossly abused by the papists to idolatry in their adoration of the host, and that, if the posture were indifferent, it ought not to be imposed as a necessary term of communion; nor did they approve of administering either of the sacraments in private, even in cases of danger; bowing at the name of Jesus; giving the ring in marriage, which they considered as derived from the papists, who make marriage a sacrament, and the ring a sort of sacred sign or symbol; the prohibition of marriage during certain times of the year, and the licensing it for money; and, lastly, the wearing of the surplice, and other vestments to be used in divine service.

In points of doctrine there was, at this time, no difference between the Puritans and Conformists; and if we add one article more to the preceding, we shall have the principal heads of controversy between the church of England and the Protestant dissenters at this day; viz. the natural right which every man has to judge for himself, and make profession of that religion he apprehends most agreeable to truth, as far as it does not affect the peace and safety of the government under which he lives; without being determined by the prejudices of education, the laws of the civil magistrate, or the decrees of councils, churches, or synods.

Towards the latter end of queen Elizabeth's reign, there arose a party, which were first for softening, and then for overthrowing, the received opinions concerning predestination, perseverance, free-will, effectual grace, and the extent of Christ's redemption. The clergy of the episcopal church began to lean towards the notions concerning these intricate points, which Arminius propagated some time after this; while, on the other hand, the Puritans adhered rigorously to the system of Calvin. Several episcopal doctors remained attached to the same system in the reign of James I., &c. and all these abettors of Calvinism, whether episcopal or presbyterian, were called doctrinal Puritans. At length, according to Mr. Fuller (Church Hist. book ix. p. 97. book x. p. 100) the name was extended to stigmatise all those who endeavoured in their devotions to accompany the minister with a pure heart, and who were remarkably holy in their conversation; so that a Puritan was a man of severe morals, a Calvinist in doctrine, and a non-conformist to the ceremonies and discipline of the church, though he did not totally separate from it.

Queen Elizabeth was violent in her opposition to the Puritans through the whole course of her reign; and besides the ordinary courts of the bishops, she erected, as we have already observed, a new tribunal, called the court of high commission, which suspended and deprived men of their livings, not by the verdict of twelve men upon oath, but by the solemn determination of three commissioners of her own nomination, founded not upon the statute law of the realm, but upon the canon law; and instead of producing witnesses in open court to prove the charge, they assumed a power of administering an oath *ex officio*, whereby the prisoner was obliged to answer all questions the court should put to him, though never so prejudicial to his own defence. If he refused to swear, he was imprisoned for contempt; and if he took the oath, he was convicted upon his own confession.

During the reign of James I. from whom the Puritans expected more indulgent treatment, they were treated with great severity, and many of them obliged to leave the kingdom, and retire to Holland; and from thence considerable numbers migrated to America, in the year 1620. All were Puritans, in the estimation of king James, who adhered to the laws of the land in opposition to his arbitrary government, though otherwise ever so good churchmen. These were called Puritans in the state; and those who scrupled the ceremonies, and adhered to the doctrines of Calvin, were church Puritans, who, though comparatively few, yet being joined by those of the other class, became the majority of the nation. The success that attended the first emigrators, who settled in that part of America afterwards called New Plymouth, engaged great numbers of Puritans, who groaned under the oppression of the bishops, and the severity of a court, by which this oppression was authorised, to follow the fortunes of these religious adventurers; and this produced a second emigration in the year 1629, which gave birth to the second grand colony, commonly known by the name of the Massachusetts Bay. The colony of Connecticut was formed by emigrants of the same class in 1636, and that of New Haven in 1637, who fled from the persecution of Laud, and the oppressions of the star-chamber and high-commission courts. Afterwards, when the Puri-

tans were not allowed to transport themselves to New England, many of them removed, with their families, into the Low Countries.

After the restoration of Charles II. in the year 1662, the name of Puritans, says bishop Burnet, was changed into that of Protestant Non-conformists, who were subdivided into Presbyterians, Independents, Baptists, and Quakers. At this time a public law, called the Act of Uniformity, was enacted, by which all who refused to observe the rites, and subscribe the doctrines, of the church of England, were entirely excluded from its communion. From this period until the reign of king William III. the Non-conformists were in a precarious and changing situation, sometimes involved in calamity and trouble, and at other times enjoying some intervals of tranquillity and certain gleams of hope, according to the varying spirit of the court and ministry, but never entirely free from perplexities and fears. But in the year 1689 their affairs took a favourable turn, when a bill for the toleration of all Protestant Dissenters from the church of England, except the Seceders, passed in parliament almost without opposition, and delivered them from the penal laws to which they had been subjected by the act of uniformity, and other acts passed under the house of Stuart.

For the other acts, see NON-CONFORMISTS, TOLERATION, &c.: from which it will appear, that every separate congregation which is held in a place duly licenced, and where a minister who has legally qualified officiates, is as completely established by the laws of England, as the Episcopalian church itself.

**PURITANICAL.** *a.* (from *puritan.*) Relating to puritans (*Walton*).

**PURITANISM.** *s.* (from *puritan.*) The notions of a puritan (*Wotton*).

**PURITY.** *s.* (*purité*, Fr. *puritas*, Lat.) 1. Cleanness; freedom from foulness or dirt (*Thomson*). 2. Freedom from guilt; innocence (*Wake*). 3. Chastity; freedom from contamination of sexes (*Shakspeare*).

**PURL.** *s.* (contracted from *purgle*.) 1. An embroidered and puckered border (*Bacon*). 2. A kind of medicated malt liquor, in which wormwood and aromatics are infused.

**To PURL.** *v. n.* To murmur; to flow with a gentle noise (*Milton*).

**To PURL.** *v. a.* To decorate with fringe or embroidery (*Ben Jonson*).

**PURLIEU.** *s.* The grounds on the borders of a forest; border; enclosure; district (*Speculator*).

**PURLINS.** *s.* In architecture, those pieces of timber that lie across the rafters on the inside to keep them from sinking in the middle of their length (*Bailey*).

**To PURLOIN.** *v. a.* (*pour* and *loin*, Fr.) To steal; to take by theft (*Denham*).

**PURLOINER.** *s.* (from *purloin.*) A thief; one that steals clandestinely (*L'Estrange*).

**PURNEAH,** a town of Hindustan, in Bengal, on a river that flows into the Ganges, 125 miles N.N.W. of Moorshedabad. Lon. 87. 40 E. Lat. 25. 47 N.

**PURPARTY.** *s.* (*pour* and *parti*, French.) Share; part in division (*Davies*).

**PURPLE.** *a.* (*poupre*, Fr. *purpureus*, Lat.)

1. Red tinged with blue (*Wotton*). 2. In poetry, red (*Dryden*).

**To PURPLE.** *v. a.* (*purpuro*, Lat.) To make red; to colour with purple (*Milton*).

**PURPLE.** *s.* The purple colour; a purple dress (*Milton*).

**PURPLE APPLE,** in botany. See ANNONA.

**PURPLE FISH,** in helminthology. See MUREX.

**PURPLES.** *s.* (without a singular.) Spots of livid red, which break out in malignant fevers; a purple fever.

**PURPLISH.** *a.* (from *purple*.) Somewhat purple (*Boyle*).

**PURPORT.** *s.* (*pourporte*, Fr.) Design; tendency of a writing or discourse (*Norris*).

**To PURPORT.** *v. a.* (from the noun.) To intend; to tend to show (*Rowe*).

**PURPOSE.** *s.* (*propos*, Fr. *propositum*, Lat.) 1. Intention; design (*Knolles*). 2. Effect; consequence (*Baker*). 3. Instance; example (*L'Estrange*).

**To PURPOSE.** *v. a.* (from the noun.) To intend; to design; to resolve (*Hooker*).

**PURPOSELY.** *ad.* (from *purpose*.) By design; by intention (*Pope*).

**PURPRISE.** *s.* (*pourpris*, old Fr. *purprism*, law Lat.) A close or enclosure; as also the whole compass of a manor (*Bacon*).

**PURPURE,** in heraldry. The colour so called, which signifies purple, is in engraving represented by diagonal lines, from the left to the right. See HERALDRY.

**PURPUREUS.** See CONVULVULUS.

**To PURR.** *v. n.* To murmur as a cat or leopard in pleasure.

**PURRE,** in ornithology. See CHARADRIUS and TRINGA.

**PURSE.** *s.* (*bourse*, Fr. *pwrs*, Welsh.) A small bag in which money is contained (*Shakspeare*).

**To PURSE.** *v. a.* (from the noun.) 1. To put into a purse (*Dryden*). 2. To contract as a purse (*Shakspeare*).

**PURSENET.** *s.* (*purse* and *net*.) A net of which the mouth is drawn together by a string.

**PURSEPROUD.** *a.* (*purse* and *proud*.) Puffed up with money.

**PURSER,** an officer aboard a man of war, appointed by the lords of the admiralty, who receives her victuals from the victualler; and is to take care, that it be in good condition, and well laid up, and stowed. He is also to see that they are carefully distributed to the officers and crew, according to the instructions which he has received from the commissioners of the navy for that purpose. To him also belongs the distribution of the slops, &c.

He is also to keep a list of the men and boys belonging to the ship, and to set down, exactly, the day of each man's admittance into pay; that the paymaster or treasurer of the navy may issue out his disbursements, and pay off the men according to the muster-book.

**PURSINESS.** **PURSVENESS.** *s.* (from *pursey*.) Shortness of breath.

**PURSIVENESS**, among farriers, a disorder common to horses, accompanied with difficulty of respiration beyond that of a common cold or cough, but short of broken-wind. It generally proceeds from a cold neglected or treated improperly, and hereby rendered chronic; and is to be attacked by the remedies best employed in obstinate colds, such as bleedings, detergents, attenuants, mercurial purges, &c.

**PURSLANE**, in botany. See **PORTULACA**.

**PURSLANE** (Sea). See **ATRIPLEX**.

**PURSLANE-TREE**. See **PORTULACARIA**.

**PURSU'ABLE**. *a.* (from *pursue*.) What may be pursued.

**PURSU'ANCE**. *s.* (from *pursue*.) Prosecution; process.

**PURSU'ANT**. *a.* (from *pursue*.) Done in consequence or prosecution of any thing.

*To PURSU'E. v. a.* (*poursuivre*, Fr.) 1. To chase; to follow in hostility (*Shakspeare*). 2. To prosecute; to continue (*Proverbs*). 3. To imitate; to follow as an example (*Dryden*). 4. To endeavour to attain (*Prior*).

*To PURSU'E. v. n.* To go on; to proceed. A gallicism (*Boyle*).

**PURSU'ER**. *s.* (from *pursue*.) One who follows in hostility (*Denham*).

**PURSU'IT**. *s.* (*poursuite*, Fr.) 1. The act of following with hostile intention (*Milton*). 2. Endeavour to attain (*Dryden*). 3. Prosecution (*Clarendon*).

**PURSUIVANT**. *s.* (*poursuivant*, Fr.) A state messenger; an attendant on the heralds (*Dryden*).

**PURSY**. *a.* (*poussif*, Fr.) Shortbreathed and fat (*Shakspeare*).

**PUR'TENANCE**. *s.* (*appertenance*, Fr.) The pluck of an animal (*Exodus*).

*To PURVEY. v. a.* (*pourvoir*, Fr.) 1. To provide with conveniences (*Spenser*). 2. To procure (*Thomson*).

*To PURVEY. v. n.* To buy in provisions (*Milton*).

**PURVEYANCE**. *s.* (from *purvey*.) 1. Provision (*Spenser*). 2. Procurement of victuals. 3. An exaction of provisions for the king's followers (*Bacon*).

**PURVEYOR**. *v.* (from *purvey*.) 1. One that provides victuals (*Raleigh*). 2. A procurer; a pimp (*Addison*).

**PURVIEW**. *s.* (from *pourvoir*, Fr.) Proviso; providing clause (*Hale*).

**PURULENCE**. **PURULENCY**. *s.* (from *purulent*.) Generation of pus or matter (*Arbuthnot*).

**PURULENT**. *a.* (*purulent*, Fr. *purulentus*, Lat.) Consisting of pus or the running of wounds (*Arbuthnot*).

**PURYSBURG**, a town of S. Carolina, in Beaufort district, built by a colony of Swiss, with a view to the culture of silk. It is seated on the river Savanna, 20 miles N.N.W. of the town of Savanna. Lon. 81.5 W. Lat. 32. 12 N.

**PUS**. A whitish, bland, cream-like fluid, heavier than water, found in phlegmonous abscesses, or on the surface of sores. It is dis-

tinguished, according to its nature, into laudable or good pus, serophulous, serous, and ichorous pus, &c.

The most generally established opinion of the nature of pus, till within the last thirty years, has been, that it was composed both of solids and fluids; nor is the opinion even now entirely exploded. It was called true, or laudable pus, to distinguish it from a similar discharge, supposed to be composed wholly of fluids, called mucus. Yet the distinctions between pus and mucus have been very ill defined: there was thought to be a difference in their appearance to the eye; but the principal mark of distinction arose from a breach of surface being believed necessary to the formation of pus, but not of mucus; consequently, when there was no breach in the solids, the discharge was considered to be only mucus.

This notion of pus must have taken its rise from an idea that the solids of the parts were broken down into pus.

The physiologists who formed this theory cannot, however, be said to have made their distinctions with great accuracy, since the discharge, in consequence of a blister being applied to the surface of the body, was admitted to be pus; although in such cases there is no loss of substance, and therefore the discharge should have been called mucus.

To ascertain a real difference between the fluid formed where there is a breach in the solids, and that met with where the surface is entire, has been considered an object meriting the attention of some of our most eminent surgeons, although the fluid formed under both these circumstances will be found to be precisely the same. This inquiry must have arisen from their adhering to the hypothesis which has been mentioned, and which not being founded upon the principles of the animal economy, can never explain, satisfactorily, any of the operations in the living body.

It will be found, upon investigation, that the appearance of a discharge produced from the secreting surface of an internal canal, or excretory duct, when the produce of the suppurative inflammation, is exactly similar to a discharge, in consequence of inflammation in any other part of the body. The only respect in which they differ is, that, in the one case, there is no breach of surface, and in the other, there most commonly appears to be one. The one is suppuration alone, the other suppuration attended by ulceration.

Mr. Home has been at considerable pains to collect those properties and circumstances which have been ascertained respecting pus; and has endeavoured, by investigating others not so well understood, to render the history of these observations, which are extracted from his work, pus will be considered as a fluid, whose formation depends upon a process in the animal economy analogous to glandular secretions. Its production, Mr. Home observes, depends upon inflammation having previously taken place in some part of the

body, either in the common reticular membrane, upon the internal surface of circumscribed cavities, or the surfaces of internal canals, which form excretory ducts of the body.

Inflammation is necessary for the formation of pus; and although a fluid, somewhat similar, is produced without any preceding inflammation, such fluids, not having all the properties of true pus, can be readily distinguished from it.

Pus, whether it is formed in the cellular membrane upon an investing membrane, or on the internal surface of an excretory duct, has exactly the same appearance and general properties. No distinctions will, therefore, be made between pus produced under this or that peculiar circumstance; believing it, when preceded by the same degree of inflammation in a healthy constitution, and when free from any extraneous substances, to be the same fluid. But as a difference in pus may arise from a variety of causes, it will be proper first to mark those properties which really belong to it in a healthy state of body, and afterwards mention the variations to which it is liable.

Pus taken from an healthy ulcer, near the source of circulation, as on the arm or breast, readily separates from the surface of the sore, the granulations underneath being small, pointed, and of a florid red colour, and has the following properties: it is nearly of the consistence of cream; is of a white colour; has a mawkish taste; and when cold, is inodorous; but when warm, has a peculiar smell. Examined in a microscope, it is found to consist of two parts, of globules, and a transparent colourless fluid; the globules are probably white, at least they appear to have some degree of opacity. Its specific gravity is greater than that of water. It does not readily go into putrefaction. Exposed to heat, it evaporates to dryness; but does not coagulate. It does not unite with water in the heat of the atmosphere, but falls to the bottom; yet, if kept in a considerable degree of heat, rises and diffuses through the water, and remains mixed with it, even after having been allowed to cool, the globules being decomposed.

Pus varies in its appearance, according to the different circumstances which affect the ulcer that forms it; such as, the degree of violence of the inflammation, also its nature, whether healthy or unhealthy; and these depend upon the state of health, and strength of the parts yielding pus. These changes arise more from indolence and irritability, than from any absolute disease; many specific diseases, in healthy constitutions, producing no change in the appearance of the matter from their specific quality. Thus, the matter from a gonorrhœa, from the small-pox pustules, the chicken-pox, and from an healthy ulcer, has the same appearance, and seems to be made up of similar parts, consisting of globules floating in a transparent fluid, like common pus; the specific properties of each of these poisons

being superadded to those of pus. Matter from a cancer may be considered as an exception; but a cancerous ulcer is never in a healthy state.

In indolent ulcers, whether the indolence arise from the nature of the parts, or the nature of the inflammation, the pus is made up of globules and flaky particles, floating in a transparent fluid; and globules and flakes are in different proportions, according to the degree of indolence: this is particularly observable in serophulous abscesses, preceded by a small degree of inflammation. That this flaky appearance is no part of true pus, is well illustrated by observing, that the proportion it bears to the globules is greatest where there is the least inflammation; and in those abscesses that sometimes occur, which have not been preceded by any inflammation at all, the contents are wholly made up of a curdy or flaky substance, of different degrees of consistence, which is not considered to be pus, from its not having the properties stated in the definition of that fluid.

The constitution and part must be in health to form good pus; for very slight changes in the general health are capable of producing an alteration in it, and even of preventing its being formed at all, and substituting in its place coagulating lymph.

This happens most readily in ulcers in the lower extremities, owing to the distance of the parts from the source of the circulation, rendering them weaker. And it is curious to observe the influence that distance alone has upon the appearance of pus.

A man had a compound fracture of the right leg, and an ulcer on the ankle of the left. He was in tolerable health, the ulcer looking well. An attack of fever came on soon after, when the ulcer on the ankle ceased to form good pus, the matter not separating readily from its surface, while the compound fracture continued to look very well; but in twelve hours more the same change had taken place in the opening of the compound fracture, which was about six inches higher up the leg than the ulcer. In irritable ulcers, the discharge is often thin, being principally made up of an aqueous fluid, possessed of an irritating quality, and containing few globules; such ulcers are commonly attended with hemorrhage from the smaller vessels, by which the discharge is very materially altered in its properties, is rendered acrid, and more ready to run into putrefaction than true pus. We find, however, in many irritable constitutions, the same appearances that were mentioned to take place in the indolent, the coagulating lymph being thrown out, and adhering firmly to the surface of the ulcer; therefore the appearance of an ulcer alone will not lead us to a correct judgment of its nature, but will only inform us whether it be healthy or unhealthy.

Although these different appearances of pus have been noticed, from their being so connected with its history as to deserve attention, they are not to be considered as belonging to

true pus, but as arising from a defect in the process, whatever it is, by which pus is formed.

Pus differs from chyle in its globules being larger, not coagulating by exposure to the air, nor by heat, which those of chyle do.

The pancreatic juice contains globules; but they are much smaller than those of pus.

Milk is composed of globules, nearly of the same size as those of pus, but much more numerous. Milk coagulates by rennet, which pus does not; and contains oil and sugar, which are not to be discovered in pus.

The cases in which pus is formed are, properly speaking, all reducible to one, which is, the state of parts consequent to inflammation. For, as far as we yet know, pus has in no instance been met with unless preceded by inflammation; and although, in some cases, a fluid has been formed independent of preceding inflammation, it differs from pus in many of its properties, as has been already observed.

In inflammation, the smaller blood-vessels become considerably enlarged; and what is curious, this takes place in the greatest degree in the veins; the small vessels are not only enlarged, but become more numerous; which does not proceed entirely from the blood being propelled further than usual in the old veins, but from new ones being formed; and this takes place in a much shorter time than has been imagined. It is highly probable, that these new vessels are so constructed, as to make the blood undergo certain changes, by which the fluid that afterwards constitutes pus is formed.

It has been long ascertained, that new vessels are generated in extravasated coagula of blood, and exudations of coagulating lymph. The following case ascertains the period in which this effect can be produced to be within twenty-four hours; and we know, that pus commonly requires a much longer time for its formation, under the same circumstances, and in similar parts.

Mr. Home performed the operation for the strangulated hernia upon a man in other respects in health, at seven o'clock in the morning. The hernial sac was laid open, and the gut, which proved to be a portion of the ilium about six inches in length, was attentively examined, previous to its being returned into the cavity of the belly. It had the natural polished surface peculiar to an intestine; and although its vessels were turgid with blood, it did not appear that they were uncommonly numerous. After the operation, the symptoms did not abate so much as might have been expected; and during the afternoon he complained of pain in the lower part of his belly. He had no passage by stool; and next morning, about seven o'clock, his pulse was scarcely perceptible to the touch; his skin cold and clammy; and about twelve o'clock at noon he died, having lived twenty-nine hours after the operation.

The body was opened, and the portion of gut which had been strangulated was found considerably inflamed, the external surface having lost its natural polish, and having seve-

ral small portions of exudated coagulating lymph adhering to it. The vessels of the gut were minutely injected, the arteries with a red-coloured injection, and the veins with a yellow one. Upon examination afterwards, all these adhering portions of coagulating lymph were found to be injected, having a considerable artery going to each of them, and a returning vein, which was larger than the artery. It is evident, therefore, that the coagulating lymph was laid upon the external surface of the gut after the operation; and we cannot suppose, that any such process as the forming new vessels could have been going on during the last five hours of his life, when the pulse in the wrist was scarcely to be felt, and the powers of life were so much weakened in every respect. We must therefore conclude, that the whole operation of throwing out coagulating lymph, and supplying it with blood-vessels after it had become solid, was effected in less than twenty-four hours.

This shows, that inflammation forms a vascular surface previous to the secretion of pus. Is it not, therefore, highly probable, that the newly formed parts are so organized as to secrete that fluid?

In considering the time required for the formation of pus, it is necessary to take notice of the periods which are found, under different circumstances, to intervene between a healthy or natural state of the parts, and the presence of that fluid after the application of some irritating substance to the skin.

In cases of wounds made into muscular parts, where blood vessels are divided, the first process which takes place is the extravasation of red blood; the second is the exudation of coagulating lymph, which afterwards becomes vascular; and the third, the formation of matter, which last does not, in common, take place in less than two days; the precise time will, however, vary exceedingly, according to the nature of the constitution, and the state of the parts at the time.

If an irritating substance be applied to a cuticular surface, upon which it raises a blister, pus will be formed in about twenty-four hours.

It is sometimes of very great consequence, and especially in cases of doubtful phthisis, to distinguish pus from mucus; and hence the means of distinguishing these two fluids was lately proposed as the subject of a prize disputation by the Æsculapian society of Edinburgh. The prize was gained by Mr. Charles Darwin, student of medicine from Lichfield.

The conclusions drawn from his experiments were, 1. Pus and mucus are both soluble in the vitriolic acid, though in very different proportions, pus being by far least soluble. 2. The addition of water to either of these compounds decomposes it. The mucus thus separated either swims in the mixture, or forms large flocculi in it; whereas the pus falls to the bottom, and forms, on agitation, an uniform turbid mixture. 3. Pus is diffusible through a diluted vitriolic acid, though mucus

is not. The same also occurs with water, or with a solution of sea-salt. 4. Nitrous acid dissolves both pus and mucus. Water added to the solution of pus produces a precipitate, and the fluid above becomes clear and green, while water and the solution of mucus form a turbid dirty-coloured fluid. 5. Alkaline lixivium dissolves, though sometimes with difficulty, mucus, and generally pus. 6. Water precipitates pus from such a mixture, but does not mucus. 7. Where alkaline lixivium does not dissolve pus, it still distinguishes it from mucus, as it then prevents its diffusion through water. 8. Coagulable lymph is neither soluble in concentrated nor diluted vitriolic acid. 9. Water produces no change on a solution of serum in alkaline lixivium, until after long standing, and then only a very slight sediment appears. 10. Corrosive sublimate coagulates mucus, but does not pus.

From the above experiments, it appears that strong sulphuric acid and water, diluted sulphuric acid, and caustic alkaline lixivium and water, will serve to distinguish pus from mucus; that the vitriolic acid can separate it from coagulable lymph, and alkaline lixivium from serum. Hence, when a person has any expectorated matter, the decomposition of which he wishes to ascertain, let him dissolve it in vitriolic acid, and in caustic alkaline lixivium; and let him add pure water to both solutions. If there is a fair precipitation in each, he may be assured that some pus is present. But if there is a precipitation in neither, it is a certain test that the mixture is entirely mucus. If the matter cannot be made to dissolve in alkaline lixivium by time and trituration, we have also reason to believe that it is pus.

**TO PUSH. v. a. (pousser, Fr.)** 1. To strike with a thrust (*Exodus*). 2. To force or drive by impulse (*Job*). 3. To force not by a quick blow, but by continued violence (*Shakspeare*). 4. To press forward: as, to push a prosecution (*Addison*). 5. To urge; to drive (*Addison*). 6. To enforce; to drive to a conclusion (*Swift*). 7. To importune; to tease.

**TO PUSH. v. n.** 1. To make a thrust (*Addison*). 2. To make an effort (*Dryden*). 3. To make an attack (*Daniel*). 4. To burst out with violence.

**PUSH. s. (from the verb.)** 1. Thrust; the act of striking with a pointed instrument (*Knolles*). 2. An impulse; force impressed (*Addison*). 3. Assault; attack (*Watts*). 4. A forcible onset; a strong effort (*Shakspeare*). 5. Exigence; trial; extremity (*Atterbury*). 6. A sudden emergence (*Shakspeare*). 7. A pimple; an efflorescence; a wheal (*Bacon*).

**PUSHER. s. (from push.)** He who pushes forward.

**PUSHING. a. (from push.)** Enterprising; vigorous.

**PUSHPIN. s. (push and pin.)** A child's play, in which pins are pushed alternately (*L'Estrange*).

**PUSILLANIMITY. s. (pusillanimité, Fr.)** Cowardice; meanness of spirit (*South*).

**PUSILLA'NIMOUS. a. (pusillanime, Fr.)** Meanspirited; narrowminded; cowardly (*Ba.*).

**PUSILLA'NIMOUSNESS. s. (from pusillanimous.)** Meanness of spirit.

**PUSS. s.** 1. The fondling name of a cat (*L'Estrange*). 2. The sportsman's term for a hare (*Gay*).

**PUSTULA. (pustula, of pus, matter.)** See **PUSTULE**.

**PUSTULE.** An elevation of the cuticle, sometimes globate, sometimes conoidal in its form, and containing pus, or a lymph which is in general discoloured. Pustules are various in their size, but the diameter of the largest seldom exceeds two lines. There are many different kinds of pustules, properly distinguished in medical authors, by specific appellations, as 1. Phlyzaciū, a small pustule containing pus, and raised on a hard, circular, inflamed base, of a vivid red colour. It is succeeded by a thick, hard, dark-coloured scab. 2. Psudracriū, a minute pustule, irregularly circumscribed, producing but a slight elevation of the cuticle, and terminating in a laminated scab. Many of these pustules usually appear together, and become confluent. When mature they contain pus; and after breaking, discharge a thin watery humour.

**PŪSTULOUS. a. (from pustule.)** Full of pustules; simply.

**TO PUT. v. a. (putter, to plant, Danish.)**

1. To lay or reposit in any place (*Milton*). 2. To place in any situation (*L'Estrange*). 3. To place in any state or condition (*Shakspeare*). 4. To repose (*Chronicles*). 5. To trust; to give up. 6. To expose; to apply to any thing (*Locke*). 7. To push into action (*Swift*). 8. To apply (*Dryden*). 9. To use any action by which the place or state of any thing is changed (*Wake*). 10. To cause; to produce (*Locke*). 11. To compromise; to consign to writing. 12. To add (*Ecclus.*). 13. To place in a reckoning (*Locke*). 14. To reduce to any state (*Shakspeare*). 15. To oblige; to urge (*Boyle*). 16. To incite; to instigate; to exhort; to urge by influence (*Addison*). 17. To propose; to state (*Swift*). 18. To form; to regulate. 19. To reach to another (*Habakkuk*). 20. To bring into any state of mind or temper (*Locke*). 21. To offer; to advance (*Atterbury*). 22. To unite; to place as an ingredient (*Locke*). 23. **TO PUT by.** To turn off; to divert (*Taylor*). 24. **TO PUT by.** To thrust aside (*Sidney*). 25. **TO PUT down.** To baffle; to repress; to crush (*Shakspeare*). 26. **TO PUT down.** To degrade (*Spenser*). 27. **TO PUT down.** To bring into disuse (*Dryden*). 28. **TO PUT down.** To confute (*Shakspeare*). 29. **TO PUT forth.** To propose (*Judges*). 30. **TO PUT forth.** To extend (*Genesis*). 31. **TO PUT forth.** To emit, as a sprouting plant (*Bacon*). 32. **TO PUT forth.** To exert (*Taylor*). 33. **TO PUT in.** To interpose (*Collier*). 34. **TO PUT in.** To drive to harbour (*Chapman*). 35. **TO PUT in practice.** To use; to exercise (*Dryden*). 36. **TO PUT off.** To divest; to lay aside (*Addison*). 37. **TO PUT off.** To defeat or delay with some artifice or excuse

(Boyle). 38. To **PUT** off. To delay; to defer; to procrastinate (*Wake*). 39. To **PUT** off. To pass fallaciously (*Swift*). 40. To **PUT** off. To discard (*Shakspeare*). 41. To **PUT** off. To recommend; to vend or obtrude (*Bacon*). 42. To **PUT** on or upon. To impute; to charge. 43. To **PUT** on or upon. To invest with, as clothes or covering (*Ben Jonson*). 44. To **PUT** on. To forward; to promote; to incite (*Shakspeare*). 45. To **PUT** on or upon. To impose; to inflict (*L'Estrange*). 46. To **PUT** on. To assume; to take (*Shakspeare*). 47. To **PUT** over. To refer (*Shakspeare*). 48. To **PUT** out. To place at usury (*Child*). 49. To **PUT** out. To extinguish (*Milton*). 50. To **PUT** out. To emit, as a plant (*Bacon*). 51. To **PUT** out. To extend; to protrude (*Genesis*). 52. To **PUT** out. To expel; to drive from (*Spenser*). 53. To **PUT** out. To make public (*Dryden*). 54. To **PUT** out. To disconcert (*Bacon*). 55. To **PUT** to. To kill by; to punish by (*Shakspeare*). 56. To **PUT** to. To refer to; to expose (*Bacon*). 57. To **PUT** to it. To distress; to perplex; to press hard (*Addison*). 58. To **PUT** to. To assist with (*Sidney*). 59. To **PUT** to death. To kill (*Bacon*). 60. To **PUT** together. To accumulate into one sum or mass (*Burnet*). 61. To **PUT** up. To pass unrevenged (*L'Estrange*). 62. To **PUT** up. To emit; to cause to germinate, as plants (*Bacon*). 63. To **PUT** up. To expose publicly: as, these goods are put up to sale. 64. To **PUT** up. To start from a cover (*Addison*). 65. To **PUT** up. To hoard (*Spelman*). 66. To **PUT** up. To hide (*Shakspeare*). 67. To **PUT** upon. To impose; to lay upon (*Shakspeare*). 68. To **PUT** upon trial. To expose or summon to a solemn and judicial examination (*Arbutnot*).

To **PUT** v. n. 1. To go or move (*Bacon*). 2. To steer a vessel (*Addison*). 3. To shoot or germinate (*Bacon*). 4. To **PUT** forth. To leave a port (*Shakspeare*). 5. To **PUT** forth. To germinate; to bud (*Shakspeare*). 6. To **PUT** in. To enter a haven (*Pope*). 7. To **PUT** in. To offer a claim (*Shakspeare*). 8. To **PUT** in for. To claim; to stand candidate for (*Locke*). 9. To **PUT** off. To leave land (*Addison*). 10. To **PUT** over. To sail cross (*Abbot*). 11. To **PUT** to sea. To set sail; to begin the course (*Bacon*). 12. To **PUT** up. To offer one's self a candidate (*L'Estrange*). 13. To **PUT** up. To advance to; to bring one's self forward (*Swift*). 14. To **PUT** up with. To suffer without resentment.

**PUT** s. (from the verb.) 1. An action of distress (*L'Estrange*). 2. A rustic; a clown (*Bramston*). 3. A game at cards. 4. **PUT** off. Excuse; shift (*L'Estrange*).

**PUT**, a game on playing cards, played with a complete pack, generally by two people, sometimes by three, and often by four, is a game at which the cards rank differently from all others, tray being the best, next the deuce, then ace, king, and so on in the usual order as at whist. After cutting for deal, &c. at which the highest put-card wins, three cards, by one

at a time, are given to each player, then the game is played in the following way. If the non-dealer throw up his cards, he loses a point, if he play, and the dealer does not lay down another to it, he gains a point; but, should the dealer either win the same, pass fit, or lay down one of equal value, forming what is styled a tie, the non-dealer is still at liberty to put, that is play, or not, and his opponent then only gains a point; then if both parties agree to go on, whoever gains all the tricks or two out of three, wins five points, which are the game; if each player obtains one trick, and the third is a tie, then neither party scores.

Four-handed put differs only in that any two of the players give each their best card to his partner, who then lays out one of his, and the game is afterwards played as in two-handed put.

If the dealer turn up any of his adversary's cards, another deal may be demanded; but, when he shews his own, he is to abide by them: and should a faced card occur, the pack must be shuffled and dealt again: when more cards than necessary are given to the non-dealer, he may either claim a fresh deal, or have the extra cards drawn out; but should the dealer give himself too many, then his opponent is entitled to a point, and may either have another deal, or draw the supernumerary cards. By-standers ought never to interfere, under penalty of paying the stakes. Either party saying *I put*, must abide the event of the game, or pay the stakes.

**PUTAGE** s. (*putain*, Fr.) In law, prostitution on the woman's part.

**PUTAMEN**. The shell of a nut and other fruits allied to it.—Hence

**PUTAMINEÆ**. The name of the thirty-first order in Linnéus's fragments, and of the twenty-fifth in his natural orders.

**PUTANISM** s. (*putanisme*, Fr.) The manner of living, or trade of a prostitute.

**PUTATIVE** a. (*putatif*, Fr. from *puto*, Lat.) Supposed; reputed (*Ayliffe*).

**PUTEOLI** (*Livy*, *Strabo*), a town of Campania; so called either from its wells, there being many hot and cold springs thereabouts, or from its stench, *putor*, caused by sulphureous exhalations (*Varro*, *Strabo*). It is now called *Puzzuoli*, and is pleasantly and advantageously situated for trade. In a very remote age, the Cumeans made it their arsenal and dockyard; and to this naval establishment gave the sublime appellation of *Dicearchia* or Just Power.

The Romans were well aware of the utility of this port, and took great pains to improve its natural advantages. Nothing remains of their works but a line of piers, built to break the force of a rolling sea: they are vulgarly called the bridge of *Caligula*, because that madman is said to have marched in triumph from *Puzzuoli* to *Baia* on a bridge, but his was a bridge of boats.

The ruins of its ancient edifices are widely spread along the adjacent hills and shores. An amphitheatre still exists entire in most of its

parts, and the temple of Serapis offers many curious subjects of observation; half of its buildings are still buried under the earth thrown upon it by volcanical commotions, or accumulated by the crumbings of the hill; the inclosure is square, environed with buildings for priests and baths for votaries; in the centre remains a circular platform, with four flights of steps up to it, vases for fire, a central altar, rings for victims, and other appendages of sacrifice, entire and not displaced; but the columns that held its roof have been removed to the new palace of Caserta. Behind this round place of worship stand three pillars without capitals, part of the pronaos of a large temple; they are of cipolline marble, and at the middle of their height are full of holes eaten in them by the file-fish.

The present city contains near 10,000 inhabitants, and occupies a small peninsula; the cathedral was a pagan temple, dedicated to the divinities that presided over commerce and navigation. Lon. 14. 40 E. Lat. 41. 15 N.

In the neighbourhood of Puteoli are many relics of ancient grandeur, of which none deserves more attention than the Campanian way paved with lava, and lined on each side with venerable towers, the repositories of the dead, which are richly adorned with stucco in the inside. This road was made in a most solid expensive manner by order of Domitian, and is frequently the subject of encomium in the poems of Statius.

**PUTEOLANA**, in mineralogy, a genus of the class earths, order argillaceous. Consisting of alumina, silica and iron, with generally some carbonat of lime; friable; mixed up with water and quicklime becoming so hard as not to be penetrated by water; easily melting in the fire into a black scoria. Three species.

1. *P. genuina*. Puzzolano; pozzolano; pouzzolano. Of a dull colour, tinged, readily obeying the magnet. Found in the volcanic mountains of Italy, even in those that are extinct, chiefly about Naples and Rome, where it is collected into tumular masses; colour dull red, brown or black; surface rough, uneven, and of a baked appearance; fracture uneven, or earthy and porous; not diffusible in cold water, but in boiling water gradually depositing a fine earth; with a small portion of lime it makes an excellent mortar, which hardens even under water.

2. *P. assimilis*. Of a dull colour, tinged, hardly obeying the magnet. Found near Chernavari in France, in Germany, and Franconia, and probably originates from decayed argillaceous stones.

3. *P. Cineres*. Volcanic ashes. Cinereous, in the form of ashes. Found in the neighbourhood of most volcanic mountains, from which they are ejected with vast force, and often to a great height and distance, frequently covering extensive surfaces, and sometimes burying whole cities; occasionally so subtle as to fill up the minutest crevices; colour brownish or reddish-grey; they effervesce

slightly with acids, have frequently a magnetic power, and usually contain about half their weight of argil, a small proportion of calx, magnesia and iron, the remainder is silex.

**PUTID.** *a.* (*putidus*, Lat.) Mean; low; worthless (*L'Estrange*).

**PUTIDNESS.** *s.* (from *putid*.) Meanness; vileness.

**PUTLOG.** *s.* *Putlogs* are pieces of timber or short poles, about seven feet long, to bear the boards they stand on to work, and to lay bricks and mortar upon (*Moxon*).

**PUTRE'DINOUS.** *a.* (from *putredo*, Lat.) Stinking; rotten (*Floyer*).

**PUTREFACTION.** The spontaneous process of decomposition which takes place in all the soft parts of animals, and in some vegetables under proper circumstances of temperature and moisture, by which they are finally disorganized, and are chiefly resolved, when with access of air, into a variety of gaseous and volatile compounds, which mingle with the atmosphere.

The doctrine of this process is still very obscure; or in other words though we know the requisite circumstances and many of the products, we are very far from possessing exact ideas concerning the mode in which the constituent parts of the animal body break up their former combinations, and produce new ones altogether different. The process of putrefaction is indeed extremely slow; and the insuperable disgust and loathing attending it seem almost to forbid a very minute inquiry into its progress. Yet it has not been altogether neglected. Becher and Stahl have described with fidelity the phenomena with which it is attended, and the circumstances necessary for its taking place. To sir John Pringle we are indebted for some important experiments on the method of retarding putrefaction; neither are the experiments of Dr. Macbride less valuable, though the consequences which he drew from them were erroneous. We are indebted also to Crell and Priestley for many valuable facts; and to Berthollet and Lavoisier for the first attempts to determine the real changes which take place, and the manner in which the new products which appear during putrefaction are formed. But notwithstanding the labours of these philosophers, and of many others, much is still wanting to enable us to trace the complicated changes which take place during putrefaction, and to account for them in a satisfactory manner.

It has been ascertained long ago, that putrefaction never takes place in those animal substances which contain only two or three ingredients, such as oils, resins, sugar; they must always be more complicated in their texture; and, perhaps, in all cases, a mixture of two or more compound bodies is necessary for speedy decomposition. But however complicated the animal substance may be, it does not putrefy unless moisture is present; for dry animal substances are not susceptible of alteration. A certain degree of heat is also necessary. Animal bodies may be kept without decomposing

## PUTREFACTION.

for any length of time at the freezing temperature. In general the higher the temperature, the more rapid is the putrefaction, provided the heat is not great enough to reduce the animal body to dryness. It has been observed, too, that putrefaction advances with more rapidity in the open air; but exposure to the air is not necessary, though it modifies the decomposition.

When these conditions are observed, and dead animal matter is left to itself, its colour becomes gradually paler, and its consistence diminishes; if it is a solid part, such as flesh, it softens, and a serous matter sweats out, the colour of which quickly changes; the texture of the part becomes relaxed, and its organization destroyed; it acquires a disagreeable smell; the substance gradually sinks down, and is diminished in bulk; its smell becomes stronger and ammoniacal. If the subject is contained in a close vessel, the progress of putrefaction, at this stage, seems to slacken; no other smell but that of a pungent alkali is perceived; the matter effervesces with acids, and converts syrup of violets to a green. But if the communication with the air is admitted, the urinous exhalation is dissipated, and a peculiar putrid smell is spread around with a kind of impetuosity; a smell of the most insupportable kind, which lasts a long time, and pervades every place, affecting the bodies of living animals after the manner of a ferment, capable of altering the fluids; this smell is corrected, and in a manner confined, by ammonia. When the latter is volatilized, the putrefactive process becomes active a second time, and the substance suddenly swells up, becomes filled with bubbles of air, and soon after subsides again. Its colour changes, the fibrous texture of the flesh being then scarcely distinguishable; and the whole is changed into a soft brown, or greenish matter, of the consistence of a poultice, whose smell is faint, nauseous, and very active on the bodies of animals. The odorant principle gradually loses its force; the fluid portion of the flesh assumes a kind of consistence, its colour becomes deeper, and it is finally reduced into a friable matter, rather deliquescent; which being rubbed between the fingers, breaks into a coarse powder like earth. This is the last state observed in the putrefaction of animal substances; they do not arrive at this term but at the end of a considerable time.

During this decomposition, a variety of gaseous bodies are emitted; these vary according to the substance exposed to putrefaction; but they consist chiefly of hydrogen gas, holding sulphur, phosphorus, and carbon, in solution; of ammonia, water, and carbonic acid, and perhaps also of azotic gas. Nitric acid seems in some cases to be formed and emitted. The earthy-like residuum, which remains after the decomposition is completed, consists of the fixed parts of the animal substance, mixed with charcoal, oil, and ammonia. Thus it appears that putrefaction consists in a total decomposition of the animal body; the elements of

which combine together two and two, and thus form a new set of less complicated bodies. But any attempt to explain the manner in which these changes take place would be exceedingly imperfect indeed; not only because we are ignorant of the strength of the affinities of the different elementary parts of animal bodies for each other, but because we do not even know the manner in which these elements are combined, and consequently we cannot know by what particular forces these compounds are destroyed.

In carcases buried in the earth, putrefaction takes place much more slowly; but it is scarcely possible to observe its progress with accuracy. The abdomen is gradually dilated with elastic fluids which make their appearance in it, and at last it bursts and discharges a horribly fetid and noxious gas; at the same time a dark-coloured liquid flows out. If the earth is very dry, and the heat considerable, the moisture is often absorbed so rapidly, that the carcase, instead of putrefying, dries, and is transformed into what is called a mummy.

Such are the phenomena when dead bodies are left to putrefy separately; but when great numbers of carcases are crowded together in one place, and are so abundant as to exclude the action of external air and other foreign agents, their decomposition is entirely the consequence of the reciprocal action of their ingredients themselves upon each other, and the result is very different. The body is not entirely dissipated or reduced to mould, but all the soft parts are found diminished remarkably in size, and converted into a peculiar saponaceous matter. This singular change was first accurately observed in the year 1786. See ADIPOCIRE.

The burial-ground of the Innocents in Paris having become noxious to those who lived in its neighbourhood, on account of the disagreeable and hurtful odour which it exhaled, it was found necessary to remove the carcases to another place. It had been usual to dig very large pits in the burial-ground, and to fill them with the carcases of the poorer sort of people, each in its proper bier; and when they were quite full, to cover them with about a foot deep of earth, and to dig another similar pit, and fill it in the same manner. Each pit held between one thousand and fifteen hundred bodies. It was in removing the bodies from these pits that this saponaceous substance was found. The grave-diggers had ascertained by long experience, that about thirty years were required before all bodies had undergone this change in its full extent. Every part of the body acquired the properties of this substance. The intestines and viscera of the thorax had completely disappeared; but what is singular enough, the brain had lost but little of its size or appearance, though it was also converted into the same substance.

This saponaceous matter was of a white colour, soft and unctuous to the touch, and melted, when heated, like tallow. It exhibited all the properties of a soap, containing,

# PUTREFACTION.

however, an excess of fatty matter. Fourcroy, who analysed it, found that it was composed of a fatty matter combined with ammonia, and that it contained also some phosphat of lime and ammonia. Diluted acids decomposed it, and separated the fatty matter; alkalies and lime, on the other hand, drove off the ammonia. When exposed to the air, it gradually lost its white colour; the ammonia, in a great measure, evaporated; and what remained had something of the appearance of wax. It absorbed water with great avidity, and did not part with it readily. Its white colour was owing to the presence of that liquid. The oily matter, when separated by means of a diluted acid, was concrete, and of a white colour, owing to the mixture of a quantity of water. When dried, it acquires a greyish-brown colour, with a lamellar and crystalline texture, like that of spermaceti; but if it has been rapidly dried, it assumes the appearance of wax. It melts when heated to 126°; when properly purified, by passing it through a linen cloth while fluid, it has scarcely any smell. Alcohol does not act upon it while cold, but at the temperature of 120° it dissolves it: when the solution cools, the fatty matter precipitates, and forms a gritty mass. With alkalies it forms a soap; and when set on fire it burns precisely like oil or fat, only that it exhales a more unpleasant odour.

Mr. Smith Gibbes found the same substance in the pit into which animal matters are thrown at Oxford after dissection. A small stream of water constantly passes through this pit; a circumstance which induced him to try whether animal muscle exposed to the action of a running stream underwent the same change. The experiment succeeded completely: he attempted, in consequence, to render this substance, to which he gave the name of spermaceti, useful in those manufactures which require tallow; but the fetid odour which it constantly exhales was an insurmountable objection. Attempts were indeed made to get over it; and a manufacture of Mr. Smith Gibbes's spermaceti was even established at Bristol.

Many attempts have been made to retard the destructive progress of putrefaction, in order to preserve animal bodies either as food or for other useful purposes; and several methods have been ascertained which prevent it from operating for a considerable time.

1. The freezing temperature is a complete preservation from putrefaction, as long as the animal substance is exposed to it. Hence the common practice of keeping meat in snow in the frozen climates of the north; and of packing fish in ice, and sending them in that state from Scotland to the London market.

2. Almost all bodies which have a strong affinity for water retard putrefaction for a longer or shorter time, doubtless by depriving the animal substances of their water, or preventing that liquid from acting upon these bodies in its usual manner. In this way the acids, sugar, alcohol, &c. seem to prevent or retard putrefaction.

3. It is well known that common salt is a powerful antiseptic. Hence the practice of salting meat, and the length of time which meat that has undergone this operation may be kept. Several other salts, especially nitre, possess the same property. In what manner these bodies act has not been ascertained; but they undoubtedly produce some chemical change upon the meat; for they alter its taste, its colour, and other sensible properties.

4. Many aromatics, such as camphor, resins, volatile oils, bitumens, and other similar bodies, act with considerable efficacy in preserving animal bodies from putrefaction. Hence their utility in embalming. In what the action of these substances consists has not been ascertained. Part of their efficacy is doubtless owing to the rapidity with which the animal substances to which they are applied lose their moisture; and something may be ascribed likewise to their odour, which keeps insects at a distance, and thus prevents the lodging of excrementitious matter, which always acts powerfully as a putrefactive ferment.

Some kinds of air are remarkably antiseptic, though this subject has not been so fully inquired into as could be wished. The most powerful of them in this respect is the nitrous air; next to it is fixed air; but the powers of the other airs are not so well known. It is probable that the antiseptic properties of fixed and nitrous air are owing to their quality of extinguishing fire, or at least that the principle is the same; but, till the nature of these two kinds of air be better known, little can be said with certainty on the subject.

Sir John Pringle made experiments to determine the powers of certain substances to promote or to prevent putrefaction. From these experiments he formed the following table, showing the relative antiseptic powers of the saline substances mentioned. Having found that two drams of beef put in a phial with two ounces of water, and placed in a heat equal to 90° of Fahrenheit's thermometer, became putrid in 14 hours, and that 60 grains of sea-salt preserved a similar mixture of beef and water more than 30 hours, he made the antiseptic power of the sea-salt a standard, to which he compared the powers of the other salts. The algebraic character + signifies that the substance to which it is annexed had a greater antiseptic power than is expressed by the numbers;

|                           |   |   |     |
|---------------------------|---|---|-----|
| Sea-salt, or the standard | - | - | 1   |
| Sal gem                   | - | - | 1 + |
| Vitriolated tartar        | - | - | 2   |
| Spiritus Mindereri        | - | - | 2   |
| Soluble tartar            | - | - | 2   |
| Sal diureticus            | - | - | 2 + |
| Crude sal ammoniac        | - | - | 3   |
| Saline mixture            | - | - | 3   |
| Nitre                     | - | - | 4 + |
| Salt of hartshorn         | - | - | 4 + |
| Salt of wormwood          | - | - | 4 + |
| Borax                     | - | - | 12  |
| Salt of amber             | - | - | 20  |
| Alum                      | - | - | 30  |

The quantities of spiritus Mindereri and of the saline mixture were such, that each of them contained as much alkaline salt as the other neutral salts.

Myrrh, aloes, asafoetida, and terra Japonica, were found to have an antiseptic power 30 times greater than the standard. Gum ammoniacum and sagapenum showed little antiseptic power.

Of all resinous substances, camphor was found to resist putrefaction most powerfully. Sir John Pringle believes that its antiseptic power is 300 times greater than that of sea-salt.

Camomile flowers, Virginian snake-root, pepper, ginger, saffron, contrayerva-root, and galls, were found to be 12 times more antiseptic than sea-salt.

Infusions of large quantities of mint, angelica, ground-ivy, green tea, red roses, common wormwood, mustard, and horseradish, and also decoctions of poppy heads, were more antiseptic than sea-salt.

Decoctions of wheat, barley, and other farinaceous grains, checked the putrefaction by becoming sour.

Chalk, and other absorbent powders, accelerated the putrefaction, and resolved meat into a perfect mucus.

**PUTREFACTIVE. a.** (from *putrefacio*, Lat.) Making rotten (*Wiseman*).

**To PUTREFY. v. a.** (*putrifier*, Fr. *putrefacio*, Lat.) To make rotten; to corrupt with rottenness (*Temple*).

**To Pu'TREFY. v. n.** To rot (*Bacon*).

**PUTRESCENCE. s.** (from *putresco*, Lat.) The state of rotting (*Brown*).

**PUTRESCENT. a.** (*putrescens*, Latin.) Growing rotten (*Arbuthnot*).

**PUTRID. a.** (*putride*, Fr. *putridus*, Lat.) Rotten; corrupt (*Waller*).

**PUTRID FERMENTATION.** The process by which a substance is decomposed and dissipated in the air, in the form of putrid gas. Every living body, when deprived of life, performs a retrograde process, and becomes decomposed. This is called fermentation in vegetables, and putrefaction in animals. The same causes, the same agents, and the same circumstances, determine and favour the decomposition in vegetables and animals, and the difference of the products which are obtained arises from the difference of the constituent parts of each. The requisites to this process are, 1. A certain degree of humidity. 2. The access of atmospheric air. 3. A certain degree of heat. See **PUTREFACTION**, as also **FERMENTATION**.

**PUTRID FEVER.** A species of typhus. See **TYPHUS GRAVIOR**.

**PUTRIDNESS. s.** (from *putrid*.) Rottenness (*Floyer*).

**PUTTTER. s.** (from *put*.) 1. One who puts (*L'Estrange*). 2. **PUTTER on.** Inciter; instigator (*Shakspeare*).

**PUTTINGSTONE. s.** In some parts of Scotland, stones are laid at the gates of great houses, which they call *puttingstones*, for trials of strength (*Pope*).

**PUTTOCK. s.** (derived by *Minshaw*, from *buteo*, Lat.) A buzzard (*Peacham*).

**PUTROCKS, or PUTTOCK SHROUDS,** in a ship, are small shrouds which go from the shrouds of the main-mast, fore-mast, and mizen-mast, to the top-mast shrouds; and if there be any top-gallant mast, there are puttocks to go from the top-mast shrouds into these. These puttocks are at the bottom seized to a staff, or to some rope which is seized to a plate of iron, or to a dead man's eyes, to which the lanniards of the fore-mast shrouds do come.

**PUTTY,** a white powder obtained by calcining an alloy of equal parts of tin and lead. The substance thus procured is true or genuine putty; it constitutes the base of most of the opaque enamels, and is used in giving a polish to metals, stones, and glass.

It is usually supposed that glaziers putty was originally composed of this genuine putty and oil; at present, however, it is nothing more than washed chalk or whiting mixed up with linseed oil; a kind of ductile paste is thus produced which is highly serviceable in fastening panes of glass into sashes, as it becomes hard after a few days exposure to the air.

**PUY,** a populous town of France, in the department of Upper Loire, seated on the mountain Anis, near the river Loire. The principal church is famous for a prodigious quantity of relics; and Our Lady of Puy is celebrated in the annals of superstition. The late canons of Puy have had kings and dauphins of France at their head. Puy has manufactures of lace and silk stuffs, and is 45 miles N.E. of Mende.

**PUYCERDA,** a strong town of Spain, in Catalonia, and capital of Cerdagna. It is seated between the Carol and Segra, in a plain, at the foot of the Pyrennees, 53 miles W. of Perpignan, and 67 N.W. of Barcelona. Lon. 1. 50 E. Lat. 42. 36 N.

**PUY-DE-DOME,** a department of France, containing part of the late province of Auvergne, and almost all Limagne, a territory 12 leagues long and six broad, one of the most fertile plains in France. The borders of this circular plain are mountains, once so many volcanoes, but now covered with habitations, herds, and flocks. Clermont is the capital.

**PUY-EN-ANJOU,** a town of France, in the department of Maine and Loire, 10 miles S.W. of Saumur, and 160 of Paris. Lon. 0. 13 W. Lat. 47. 6 N.

**PUYLAURENS,** a town of France, in the department of Tarn, eight miles S.W. of Castres, and 23 E. of Toulouse. Lon. 1. 57 E. Lat. 43. 35 N.

**To PUZZLE. v. a.** (for *postle*, from *pose*. *Skinner*.) 1. To perplex; to confound; to embarrass; to entangle; to gravel; to put to a stand; to tease (*Shakspeare*. *Clarendon*). 2. To make intricate; to entangle (*Addison*).

**To PuZZLE. v. n.** To be bewildered in one's own notions; to be awkward (*L'Estrange*).

**PuZZLE. s.** (from the verb.) Embarrassment; perplexity (*Bacon*).

**PUZZLER.** *s.* (from *puzzle*.) He who puzzles.

**PUZZOLANA**, or **POZZULANA**, a kind of earth found about Puteoli, Baiæ, and Cumæ, in the kingdom of Naples. It is thrown out from the burning mouths of volcanoes, in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it at a considerable distance. Puzzolana is of a grey, brown, or blackish colour; of a loose, granular, or dusty and rough, porous or spongy texture, resembling a clay hardened by fire, and then reduced to a gross powder. It has various heterogeneous substances mixed with it. Its specific gravity is from 2.5 to 2.8; and it is, in some degree, magnetic: it scarcely effervesces with acids, though partially soluble in them. It easily melts *per se*; but its most distinguishing property is, that it hardens very suddenly when mixed with one-third of its weight of lime and water; and forms a cement which is more durable in water than any other. According to Bergman's analysis, 100 parts of it contain from 55 to 60 of siliceous earth, 20 of argillaceous, 5 or 6 of calcareous, and from 15 to 20 of iron. Its effects, however, in cement may perhaps depend only on the iron which has been reduced into a particular substance by means of subterraneous fires; evident signs of which are observable in the places where it is obtained. See **PUTEOLANA**.

**PUZZUOLI.** See **PUTEOLI**.

**PYANEPSIA**, an Athenian festival, celebrated in honour of Theseus and his companions after their return from Crete. Some suppose, that it was observed in commemoration of the Heraclidæ.

**PYCNOGONUM**, in the entomology of Fabricius, a tribe of the genus **PHALANGIUM**, which see.

**PYCNOTYLE**, in the ancient architecture, is a building where the columns stand very close to each other; only one diameter and a half of the column being allowed for the intercolumniations. According to Mr. Evelyn, the pycnostyle chiefly belonged to the composite order, and was used in the most magnificent buildings; as at present in the peristyle at St. Peter's at Rome, which consists of near 300 columns; and in such as yet remain of the ancients, among the ruins of Palmyra.

**PYCNOTICS.** (from *πυκνω*, to condense.) Incrassant or astrigent medicines.

**PYDNA**, a town of Macedonia, where Cassander massacred Olympias the mother of Alexander the Great, his wife Roxane, and his son Alexander. Pydna is famous for a battle fought there, B. C. 168, between the Romans under Paulus and king Philip, in which the latter was conquered.

**PYGARGUS**, in ornithology. See **FALCO**.

**PYGMÆI**, a nation of dwarfs, in the extreme parts of India, or in Æthiopia. Some authors affirm, that they were no more than one foot high. Aristotle says that they lived under the earth, and that they came out in the

harvest time with hatchets to cut down the corn as if to fell a forest. They made war against certain birds, called cranes, which came yearly from Scythia to plunder them. They were originally governed by a princess, who was changed into a crane, for boasting herself fairer than Juno.

**PYGMALION**, in fabulous history, a king of Tyre, son of Belus, and brother to the celebrated Dido, who founded Carthage. He became odious by his cruelty and avarice. He murdered Sichæus, Dido's husband, because he was the most powerful and opulent of the Phœnicians, but, instead of obtaining the riches which he desired, Pygmalion was shunned by his subjects, and Dido, to avoid his cruelty, fled with her husband's treasure, and a large colony to Africa, where she founded a city. (See **CARTHAGE**.)—Pygmalion died in the 56th year of his age, and in the 47th of his reign.—2. A celebrated statuary of the island of Cyprus, who, according to the mythologists, became enamoured of a beautiful statue of marble which he had made, and at his request the goddess of beauty changed the statue into a woman, whom he married.

**PYGMÆAN.** *a.* (from *pigmy*.) Belonging to a pigmy (*Milton*).

**PYGMY.** *s.* (*pygmæe*, Fr. *πυγμαῖος*.) A dwarf; one of a nation fabled to be only three spans high, and after long wars to have been destroyed by cranes. See **PIGMÆI**.

**PYLADES.** The most celebrated of this name is a son of Strophius, king of Phocis, by one of the sisters of Agamemnon. He was educated, together with his cousin Orestes, with whom he formed the most inviolable friendship, and whom he assisted to revenge the murder of Agamemnon, by assassinating Clytemnestra and Ægisthus. He also accompanied him into Taurica Chersonesus, and for his services Orestes rewarded him, by giving him his sister Electra in marriage. The friendship of Orestes and Pylades became proverbial. See **ORESTES** and **ELECTRA**.

**PYLÆ**, a town of Asia, between Cappadocia and Cilicia (*Cic.*).—The word *Pylæ*, which signifies gates, was often applied by the Greeks to any streights or passages which opened a communication between one country and another, such as the streights of Thermopylæ, or Persia, Hyrcania, &c.

**PYLE** (Thomas), M. A. was born near Holt, Norfolk, 1674, and educated at Caius college, Cambridge. He was minister of King's Lynn, and engaged warmly in the Bangorian controversy, and for his services was made prebendary of Salisbury, by Dr. Hoadly, and two of his sons also were presented to prebends in the church of Winchester. His paraphrase on the acts, and all the epistles, is an excellent work. He published besides 3 vols. of sermons, and died 1757.

**PYLORIC ARTERY.** A branch of the hepatic artery.

**PYLORUS.** (*πυλωρος*, from *πύλω*, to guard an entrance; because it guards, as it were, the entrance of the bowels.) The inferior aperture

of the stomach, which opens into the intestines.

**PYLOS**, a town of Messenia, situate on the western coast of the Peloponnesus, opposite the island Sphacteria in the Ionian sea. It was built by Pylos, at the head of a colony from Megara.—2. A town of Elis, at the mouth of the river Alpheus, between the Peneus and the Selleis.—3. Another town of Elis. These three cities disputed their respective right to the honour of having given birth to the celebrated Nestor son of Neleus.

**PYRACANTHA**, in botany. See **MES-PILUS**.

**PYOSIS**. (from *πυος*, pus.) Suppuration. See **PUS**.

**PYRALIS**, in entomology, a tribe of the genus *phalæna geometra* in the system of Gmelin; and a distinct tribe in the system of Fabricius. See **PHALÆNA**.

**PYRAMID**, *s.* (*pyramide*, Fr. *pyramide*.) A solid figure, whose base is a polygon, and whose sides are plain triangles, their several points meeting in one, called the **vertex** of the pyramid.

Hence the superficies of a given pyramid is easily found by measuring these triangles separately; for their sum added to the area of the base, is the surface of the pyramid required.

It is no less easy to find the solid content of a given pyramid; for the area of the base being found, let it be multiplied by the third part of the height of the pyramid, or the third part of the base by the height, and the product will give the solid content, as is demonstrated by Euclid, lib. 12. prop. 7.

If the solid content of a frustum of a pyramid is required, first let the solid content of the whole pyramid be found; from which subtract the solid content of the part that is wanting, and the solid content of the frustum or broken pyramid will remain. See **FRUSTUM**.

Every pyramid is equal to one-third of its circumscribing prism, or one that has the same base and height. All pyramids are in a ratio compounded of their bases and altitudes; so that, if their bases are equal, they are in proportion to their altitudes; and vice versa.

Equal pyramids reciprocate their bases and altitudes; that is, the altitude of one is to that of the other, as the base of the one is to that of the other.

**PYRAMID**, in architecture: this form we derive from the Egyptians, a people who conceived and executed unparalleled works, which are, however, more remarkable for their strength and durability than elegance of outline, and beauty of execution. According to Herodotus, the people alluded to considered the pyramidal form as emblematic of human life, the broad base representing the commencement, and the gradation, to a point, the termination of our existence in the present state; hence they used it for sepulchral purposes: it would be absurd to contradict this assertion, as the period of their erection is too remote for enquiry, with any probable success: but there is another obvious reason for the adoption of

the shape, which of all others is most decidedly calculated to resist the operations of time. Admitting a monarch to have conceived an idea of rendering his tomb almost everlasting, it was impossible to invent an outline less liable to injury from the assaults of wind and rain, and the very disposition of the stones made it impossible that it should fall even through the operations of an earthquake, besides the immense extent of their bases, and the solidity of the workmanship made it highly improbable that his successors, or the people, would be at the trouble and expense of destroying it through disrespect to his memory; this circumstance, perhaps, united with the former consideration, were sufficient inducements for the selection of the pyramid for monuments.

Some authors derive the word from the Greek for wheat and its receptacle, and those assert that pyramids were originally built by the Patriarch Joseph as granaries; others derive it from the word *πυρ*, fire, thinking that the pyramidal shape resembles the ascent of flame. Many writers are of opinion that the Egyptian pyramids were erected by the children of Israel during their slavery. The last of them, it is well known, bears strong indications of the unfinished state in which the enterprize was left by the workmen: it appears to have been suddenly abandoned by those employed on it. Profane historians, also, name the chiefs of the Hebrew people as the builders of these mountainous works.

Of these pyramids those at Gizeh are the most gigantic; and the most enormous, or the great pyramid, is situated near Memphis. Herodotus says, he was informed the latter covered the remains of Cheops, and another adjoining those of his brother Cephrenes, who succeeded him; the first only having inner galleries, or passages. Although much dependence cannot be placed upon the further accounts of this ancient writer, it seems highly probable that an 100,000 men may have been constantly employed, for 20 years, in erecting the immense pile, and that Cheops became detested by the people, who were thus taken from more useful employments, as well as by the bulk of the population, who found the taxes demanded of them appropriated to a purpose utterly unproductive of future advantage.

When M. Savary visited the pyramids of Gizeh, the country was under the government of its present natives, whose kiaschif, or governor, for the above district, exacted a small tribute from travellers, and in return provided them with an escort, as a protection against the Arabs, who seized every opportunity to plunder them. The gentleman just mentioned, accompanied by some friends and the guards furnished by the kiaschif, departed from Gizeh at an hour after midnight, and were soon after gratified with a view of the two greatest pyramids, on the summits of which the moon shone with full splendour; as they approached them they assumed the appearance of vast pointed rocks penetrating the clouds. At half an hour past three in the morning the company

## PYRAMID.

prepared to enter the passages of the great pyramid by taking off great part of their clothing, and each taking a lighted torch in their hands, thus prepared they began a long descent, which at last became so much contracted that the party were compelled to crawl upon their hands and knees; this terminating, they commenced an ascent nearly under the same uncomfortable circumstances, except that they proceeded on their knees, and made use of their hands against the sides to facilitate their progress, and this mode of getting forward was necessary, as the stone at the bottom of the passage did not afford sufficient level for a firm step; when in this dismal gallery they were so imprudent as to discharge a pistol, the report of which long echoed and re-echoed through the place, and alarmed numbers of bats who darted against them and extinguished some of their torches. Succeeding in their efforts, they arrived at the upper termination of the second passage, where they passed through a very small door into a large oblong apartment, entirely composed of granite, seven enormous blocks of which formed the ceiling.

At one extremity of this apartment M. Savary saw an empty marble sarcophagus composed of one piece, but without a lid, and fragments of earthen vases lay scattered over the floor of the room; they also visited a second chamber, situated beneath that just described, and of smaller dimensions, which contained the entrance of a conduit then filled with rubbish. Satisfied with the progress they had made, the party descended by the passage already noticed, and with some difficulty avoided a deep and dangerous well on their left hands; on their arrival in the open air, each person observed that his companions were pale and exhausted by the heat they endured when immured within the frightful abyss they had just explored.

After having rested their weary limbs, and recovered their strength and spirits, the party began to ascend the exterior of the pyramid, which consists, according to their enumeration, of above 200 gradations of stone, varying from two to four feet in height. This operation, fatiguing, and severely laborious, occupied an hour; but on their reaching the summit they had the satisfaction of seeing that the rays of the approaching sun were darted on the points of Mokaltam, and not long after they beheld it rise from behind that mountain; the landscape, thus illuminated, they perceived, with infinite pleasure, the Nile, and the adjoining fruitful fields, Gizeh, Grand Cairo, and part of the Delta, forming a striking contrast with the remainder of the view composed of sterile hills and wide spreading sands, with the intervening pyramids of Sakkara, three leagues from their then situation.

Fully sated with the rich prospect before them, they cut their names on the upper stones of the pyramid, and descended with the utmost caution, as this was a far more dangerous undertaking than the ascent: having reached the base in safety, they paced round it and contem-

plated the rugged mass with terror, which strongly resembled a vast pile of detached rocks when near it, but at a distance, the inequalities are lost, and the sides appear plain surfaces. The form of this immense monument prevents an accurate measurement of its dimensions, without severe labour and imminent danger; consequently, those authors who give them may have judged from mere conjecture. Herodotus mentions its reputed height, in his time, to have been 800 feet, and the width of each side of the base the same; Strabo made it 625 feet; but Diodorus reduces it to 600; modern observers have agreed with Strabo, and some of those bring it below Diodorus; if, however, an average may be permitted of these various accounts, that will amount to more than 500 feet.

One cause of the difference between the assumed heights is, that the pyramid is measured or observed on different sides; the north-east angle is most frequently ascended, being the least damaged, but this part is exposed to the deserts of Libya, whence vast quantities of sand are driven by the wind against it, and the number of visible gradations are diminished by its accumulation; it is, therefore, evident, that all admeasurements should be made at the opposite angle, where it is probable the rise in the earth has been less considerable, and yet to arrive at any degree of accuracy that should be ascertained by digging. Strabo mentions that the stone which closed the entrance to the apartments within the pyramid, was situated nearly half way up one of the sides; were this the fact, a very great rise in the neighbouring earth must have occurred, as it now appears to be not more than 100 feet from the base. Herodotus informs us, that the great and next pyramid, in size, were covered with white marble; and Diodorus and Pliny supposed they were wholly formed of that rich material: enough still remains on both to confirm the truth of the former assertion, which has escaped the labours of the Arabs, to whose indefatigable researches to discover supposed treasures within we are indebted for the finding the entrance to the passage, and that the pyramid was intended as a sepulchral monument for the Egyptian princes.

Denon, who accompanied the ever-memorable expedition from France to Egypt, is the last visitor of the pyramids, and to him we are obliged for the following particulars of their present state.

General Buonaparte had determined to examine the great pyramids of Gizeh, and ordered an escort of near 300 men; Denon had the address to become one of the party, and they proceeded on the undertaking rather late in the day, owing to the difficulty of assembling the persons who composed it. Boats were procured to convey them, and they passed through the inundating trenches of the Nile to the boundary of the desert, within half a league of the pyramids. As they approached them Denon perceived that their sloping and angular forms had the effect of reducing their real height, which the eye was thus prevented from measuring with accu-

## PYRAMID.

racy; besides as there are no other objects in their vicinity by which a comparison can be made, the mind is led to think of nature's grandest production, the mountain, and in consequence the pyramid shrinks into insignificance. This impression was, however, very soon effaced, for as Denon advanced he saw an 100 persons assembled near the base, the deception instantly vanished, a comparison was formed, and the stupendous pile assumed all its appropriate majesty.

The party ascended a small heap of rubbish and sand, the probable remains of the trench of the first of these edifices which presents itself, and now conducting to the opening through which it may be reached, this aperture, said by Denon to be about 60 feet from the base, is hidden by a general facing of stone, forming the third or inner enclosure to the solitary entrenchment surrounding the pyramid. Large stones are laid horizontally on the sides of the entrance, and above those are others of enormous size, fitted at the ends so as to lean against each other, by this means rendering their fall or derangement impossible through the superincumbent weight. Hence commences the first gallery with a direction towards the centre and base of the monument; this gallery is now greatly clogged with the drifted sand of the desert, and the rubbish originally made by the efforts to explore the secrets of the edifice, it is consequently difficult of access. "At the extremity of this gallery," says Denon, "two large blocks of granite are met with, which form a second partition to this mysterious passage." The interruption made by those in the progress of past research was such, that various fruitless attempts have been made to surmount the impediment, and some have even had the folly to cut into the solid mass composing the pyramid, "but this proving unsuccessful, they have returned some way, have passed round two blocks of stone, climbed over them, and thus discovered a second gallery of so steep an ascent, that it has been necessary to hew steps in the ground in order to mount it. This gallery leads to a kind of landing-place in which is a hole usually called the well, which is the opening to an horizontal gallery leading to a chamber known by the name of the queen's chamber, without ornament, cornice, or any inscription whatever.

"Returning to the landing-place, an aperture, in a perpendicular direction, leads to the principal gallery, and this terminates in a second landing-place where a third and last partition is situated; as this is constructed with a greater degree of architectural care and propriety than the rest of the building, it may be inferred that the Egyptians considered it proper to guard the immediate deposit of their dead with peculiar attention.

"Lastly comes the royal chamber, containing the sarcophagus, a narrow sanctuary, which is the sole end and object of an edifice so stupendous, so colossal."

Mr. Bryant is of opinion that the pyramids

were temples erected in honour of the Deity; and a very ingenious writer in the Gentleman's Magazine for June 1794 has done much to prove that they were altars dedicated to the sun, the first and greatest god in every pagan calendar.

"Our English word pyramid (says he) is directly derived from the Latin *pyramis*, and mediately from the Greek *πυραμς*; all denoting the same mathematical figure. The original of the whole seems to be the Egyptian word *pyramoua*, which, we are told by Oriental scholars, signifies light, or a ray of light. From this Coptic vocable the word *πυρ* in Greek, signifying fire, is probably descended; as the flames of fire assume that conical or pyramidal form which the solar rays commonly display; and as it is natural for the mind to distinguish its objects rather by their external qualities, and those obvious and interesting appearances which they exhibit to the senses, than by their constituent and inseparable properties.

"The ancient Egyptians seem to have penetrated very far into the mysteries of nature; and although their superstition appears at first sight to be extremely gross and absurd, yet it is very probable that their deities were only emblematical personages, representing by sensible images the grand effects or presiding principles which they supposed to exist in the universe. Thus the moon was called Isis, and the sun Osiris; and to the honour of this last deity, from whose visible influence and creative energy all things seem to spring into existence, it is not improbable that the Egyptians erected those stupendous monuments, and dedicated them to him as temples or altars. It was natural to build them in that shape which the rays of the sun display when discovered to the eye, and which they observed to be the same in terrestrial flame, because this circumstance was combined in their imaginations with the attribute which they adored. If they were temples dedicated to the sun, it seems a natural consequence that they should likewise be places of sepulture for kings and illustrious men, as the space which they covered would be considered as consecrated ground. This hypothesis is common, and is not contradicted by the present reasoning. But, considering them as altars, and as most travellers agree that they were never finished, but terminate in a square horizontal surface, it would not be refining too much to venture an assertion that, in great and solemn acts of adoration, the Egyptians constructed fires, the flames of which should terminate in the vertex of the pyramid, and so complete that emanation of their deity which they admired and adored. As far, therefore, as we are justified in forming any conclusion on so dark a subject, we may venture to say, that the Egyptian pyramids were temples or altars dedicated to the sun, as the material representative of that invisible power which creates, governs, and pervades, the whole system of nature."

Another ingenious investigator, Mr. Clarkson, has been recently delivering an interesting

course of lectures on the pyramids, to the London Philosophical Society, at their rooms in Crane-court, in which he has completely established the point that they were not sepulchres, (as has been usually imagined) but temples dedicated to the mysteries of solar fire. For a tolerably copious analysis of Mr. Clarkson's disquisitions, see Tilloch's Philosophical Magazine, No. 166.

**PYRAMIDAL.** **PYRAM'DICAL.** *a.* (from *pyramid*.) Having the form of a pyramid (*Locke*).

**PYRAMIDAL NUMBERS** are the sums of polygonal numbers, collected after the same manner as the polygonal numbers themselves are extracted from arithmetical progressions. See **FIGURATE NUMBERS**.

These are particularly called first pyramidal. The sums of first pyramidal are called second pyramidal. And the sums of those third pyramidal; and so on, *ad infinitum*. Particularly those arising from triangular numbers are called prime triangular pyramidal; those arising from pentagonal numbers are called prime pentagonal pyramidal, &c.

The numbers 1, 4, 10, 20, 35, &c. formed by adding }  
the triangulars } 1, 3, 6, 10, 15, &c.  
are usually called simply by the name of pyramidal; and the general formula for finding

them is  $n \times \frac{n-1}{2} \times \frac{n-2}{3}$ ; so the 4th pyramid is found by substituting 4 for  $n$ ; the 5th by substituting 5 for  $n$ ; &c. See **FIGURATE NUMBERS**, and **POLYGONAL NUMBERS**.

**PYRAMIDALIS.** (from *πυραμις*, a pyramid.) In anatomy. Fallopius, who is considered as the first accurate describer of this muscle, first gave it the name of pyramidalis, from its shape. But Vesalius seems to have been acquainted with it, and to have described it as a part of the rectus. It is a very small muscle, situated at the bottom of the fore part of the rectus, and is covered by the same aponeurosis that forms the anterior part of the sheath of that muscle. It arises, by short tendinous fibres, from the upper and fore part of the pubis. From this origin, which is seldom more than an inch in breadth, its fibres ascend somewhat obliquely, to be inserted into the linea alba, and inner edge of the rectus, commonly at about the distance of two inches from the pubis, and frequently at a greater or less distance, but always below the umbilicus. In some subjects the pyramidalis is wanting on one or both sides, and when this happens, the internal oblique is usually found to be of greater thickness at its lower part. Now and then, though rarely, there are two at one side, and only one at the other, and M. Sabbatier has even seen two on each side. Fallopius, and many others after him, have considered it as the congener of the internal oblique; but its use seems to be to assist the lower part of the rectus.

**PYRAMIDALIS FACIEI.** See **LEVATOR LABII SUPERIORIS ALÆQUE NASI**.

**PYRAMIDICALLY.** *ad.* (from *pyramidal*.) In form of a pyramid (*Broome*).

**PYRAMIDOID**, is sometimes used for the parabolic spindle, or the solid formed by the rotation of a semiparabola about its base or greatest ordinate. See **PARABOLIC SPINDLE**.

**PYRAMUS**, in fabulous history, a youth of Babylon, became enamoured of Thisbe, a beautiful virgin, who dwelt in the neighbourhood. The flame was mutual, and the lovers, whom their parents forbid to marry, regularly interchanged sentiments through the chink of a wall, which separated their houses. They both agreed to elude the vigilance of their friends, and to meet at the tomb of Ninus, under a white mulberry tree, without the walls of Babylon. Thisbe came first to the appointed place, but the sudden arrival of a lioness frightened her away; and as she fled, she dropped her veil, which the lioness found and covered with blood. Pyramus soon arrived; he found Thisbe's veil bloody, and concluding that she had been torn to pieces by wild beasts, he stabbed himself. Thisbe, when her fears vanished, returned from the cave, and at the sight of the dying Pyramus, she fell upon the sword still reeking with his blood. The tree, as the poets mention, was stained with the blood of the lovers, and ever after bore fruit, but of the colour of blood.

**PYRBAUM**, a town of the upper palatinate of Bavaria, capital of a lordship of the same name. It is 13 miles S.E. of Nuremberg.

**PYRE.** *s.* (*pyra*, Latin.) A pile on which the dead are burnt (*Dryden*. *Pope*).

**PYRENE.** The most remarkable of this name is a daughter of Bebrycius, king of the southern parts of Spain. Hercules offered violence to her before he went to attack Geryon, and she brought into the world a serpent, which so terrified her, that she fled into the woods, where she was torn to pieces by wild beasts.—2. A small village in Celtic Gaul, near which, according to some, the river Ister took its rise.

**PYRENNEES**, mountains which form the boundaries between France and Spain, and extend from the Mediterranean to the Atlantic, about 200 miles in length, and, where widest, 100 in breadth, but under different names, and in a variety of branches. Over these mountains there are only five passages from one country to the other, the three principal of which are from St. Sebastian to St. Jean de Luz; from Pamplona to St. Jean de Luz; and from Jonqueira to Perpignan. These mountains yield great quantities of timber for shipping, which is conveyed, by means of the Ebro and other streams, to the sea, with abundance of pitch and tar. The Pyrennees give name to three of the French departments.

**PYRENNEES** (Eastern department of), one of the new divisions of France, bounded on the north by the department of the Arriege and

the Aude, on the east by the Mediterranean, on the south and west by Spain; about fifty-eight miles from east to west, and from eighteen to twenty-five from north to south. This tract was heretofore the province of Rousillon. Perpignan is the capital.

**PYRENNEES** (Lower department of), one of the divisions of France, bounded on the north by the department of the Landes and Gers, on the east by the department of the Upper Pyrennees, on the south by Spain, and on the west by the sea: seventy miles in length, and from fifteen to forty-five in breadth. It is composed of the provinces of Bearn, Navarre, and part of Gascony. Pau is the capital.

**PYRENNEES** (Upper department of), one of the divisions of France, bounded on the north by the department of the Gers, on the east by the department of the Upper Garonne, on the south by Spain, and on the west by the department of the Lower Pyrennees: fifty-three miles in length, and from twenty-five to thirty-eight in breadth; a small district towards the north is scarcely more than seven miles in breadth. This department is composed chiefly of the province of Bigorre. Tarbes is the capital.

**PYRENIUM**, in botany, a genus of the class cryptogamia, order fungi. Fungus globular, naked, entire, inclosing naked, conglomerate seeds like a nucleus. Four species; all exotics.

**PYRETHRUM**. Feverfew. In botany, a genus of the class syngenesia, order polygamia superflua. Receptacle naked; seeds crowned with a membranaceous margin; calyx hæmisphepherical, imbricate; the scales rather acute and scarious on the margin. Twenty-six species, scattered over the globe; two of them common to our own wastes or sea-coasts. They may be thus subdivided:

A. Ray of the flower white.

B. Ray of the flower yellow.

The ancient Romans, we are told, employed the root of this plant as a pickle. In its recent state it is not so pungent as when dried, yet if applied to the skin, it is said to produce inflammation. Its qualities are stimulant; but it is never used, except as a masticatory, for relieving tooth-achs, rheumatic affections of the face, and paralysis of the tongue, in which it affords relief by stimulating the excretory ducts of the salival glands.

**PYRETHRUM SYLVESTRE**. See **PTARMICA**.

**PYRETOLOGY**. (*πυρετολογία*, from *πυρ*, fire, or heat, and *λογος*, a discourse.) A discourse or doctrine on fevers.

**PYREXIA**. (*πυρεξία*, from *πυρ*, fire.) Fever.

**PYREXIE**. Febrile diseases. The first class of Cullen's nosology; characterised by frequency of pulse after a cold shivering, with increase of heat, and especially, among other impaired functions, a diminution of strength.

**PYRGOTELES**, a celebrated engraver on gems, in the age of Alexander the Great. He had the exclusive privilege of engraving the conqueror, as Lysippus was the only sculptor who was permitted to make statues of him.

**PYRIFORMIS**. (*pyriformis*, from *pyrus*,

a pear, and *forma*, a shape, shaped like a pear.) *Pyriformis*, seu *iliacus externus* of Douglas. In myology. Spigelius was the first who gave a name to this muscle, which he called *pyriformis*, from its supposed resemblance to a pear. It is a small radiated muscle, situated under the *glutæus maximus*, along the inferior edge of the *glutæus minimus*. It arises by three, and sometimes four tendinous and fleshy origins, from the anterior surface of the second, third, and fourth pieces of the *os sacrum*, so that this part of it is within the pelvis. From these origins the muscle grows narrower, and passing out of the pelvis, below the niche in the posterior part of the ilium, from which it receives a few fleshy fibres, is inserted, by a roundish tendon of an inch in length, into the upper part of the cavity at the root of the *trochanter major*. The use of this muscle is to assist in moving the thigh outwards, and in moving it a little upwards.

**PYRITES**, in mineralogy, a name first given by ancient mineralogists to the native sulphuret of iron, because, when struck against a piece of steel or other hard body, it gives out sparks of fire; and when heated red-hot, the sulphur that it contains burns with a lambent blue flame. It occurs massive, and frequently crystallized: the forms of its crystals are various, but the most common is the cube regular, or modified by truncation of the angles or edges, or acumination of three planes on the angles: the octaedron, dodecaedron, and icosaedron, also sometimes occur.

Its colour is brass-yellow, varying a little in the shade, and the lustre is always fully metallic: it is opaque. The fracture is uneven. It is brittle; its hardness is such as to strike fire with steel; its specific gravity is from 4.6 to 4.8. By friction it exhales a sulphureous smell. This odour is strong when it is heated before the blow-pipe; it gives at the same time a blue flame; and at length a globule of a brownish colour. It is soluble in nitric acid, with the disengagement of red vapours. It is not sensibly magnetic. Various analyses of it have been given: according to those executed by Mr. Hatchet, it consists of

|              |       |
|--------------|-------|
| Sulphur..... | 52    |
| Iron.....    | 48    |
|              | <hr/> |
|              | 100   |

Besides this variety, which may be named common pyrites, there are some others which differ principally in structure, or in the form under which they occur. The striated or radiated pyrites presents a striated fracture, the striae being generally diverging.

It is rather more liable to tarnish than the preceding, and decomposes more readily in a humid atmosphere. According to Mr. Hatchet's analysis, it consists of

|              |       |
|--------------|-------|
| Sulphur..... | 54    |
| Iron.....    | 46    |
|              | <hr/> |
|              | 100   |

## P Y R

The capillary pyrites occurs in delicate capillary crystals, grouped, parallel, diverging, or interwoven, slightly flexible, having a metallic lustre, and a colour passing from yellow to steel-grey. There is, lastly, the hepatic pyrites, so named from the liver-brown colour, which it assumes from exposure to the air. In the fresh fracture its colour is pale brass-yellow, inclining to steel-grey. It occurs massive, of various imitative forms, and crystallized in six-sided prisms, or six-sided pyramids; it has less lustre than the others, and is more subject to decomposition. What has been named magnetic pyrites, distinguished, as the name implies, by its magnetic quality, of which the others are destitute, has been considered as forming a distinct species. Its colour is deeper, being intermediate between brass-yellow and copper-red, and approaching even to brown, often tarnished: its lustre is also inferior, but is still metallic. It occurs only massive or disseminated. Its fracture is compact: it is hard and brittle: its specific gravity is 4.5. It appears from Mr. Hatchet's analysis of it to differ from the other iron pyrites, in containing a larger proportion of metal, to which, no doubt, its quality of being attracted by the magnet is owing.

Besides the ferruginous pyrites, modern mineralogists distinguish two other species, the cupreous and the arsenical, the former of which is a sulphuret of copper, and the latter a compound of ferruginous pyrites and arsenic. All, however, have a general resemblance in their external appearance, the colour varying in each of them from a yellowish white to a gold yellow; and they have all a high metallic lustre.

**PYRMONT**, a town of Westphalia, in a county of the same name, with a fine citadel. Near it are mineral waters, well known to all Europe, and often frequented by persons of the highest rank. It is seated in a delightful valley, between high mountains, 38 miles S.W. of Hanover. Lon. 9. 20 E. Lat. 51. 57 N.

**PYRMONT WATER.** A general view of the analysis of this water will show that it stands the first in rank of the highly carbonated chalybeates, and contains such an abundance of carbonic acid, as not only to hold dissolved a number of carbonic salts, but to show all the properties of this acid uncombined, and in its most active form. Pyrmont water is likewise a strong chalybeate, with regard to the proportion of iron; and it is besides a very hard water, containing much selenite and earthy carbonats. The diseases to which this mineral water may be advantageously applied are the same as those for which the spa and others of the acidulated chalybeates are resorted to, that is, in all cases of debility that require an active tonic that is not permanently heating; various disorders in the alimentary canal, especially bilious, vomiting, and diarrhæa, and complaints that originate from obstructed menstruation. See **MINERAL WATERS**.

**PYROCHROA.** In the entomology of Fabricius, a tribe of the genus **LAMPYRIS**, which see.

## P Y R

**PYROLA.** Winter-green. In botany, a genus of the class decandria, order monogynia. Calyx five-parted; petals five; capsule superior, five-celled, opening at the angles, many-seeded; anthers with two pores. Six species; four found wild in our own woods, one in America, and one in Europe, Asia and America.

**PYROLIGNEOUS ACID.** **PYROMUCOUS ACID.** **PYROTARTAREOUS ACID.** All these are empyreumatic acids, and differ but little from each other in taste, colour, or smell. They are obtained from a variety of vegetable substances heated strongly in close vessels so as to destroy their organization, and for the most part consist of a bitterish, pungent, and sour liquor, which is always more or less turbid and dark-coloured; incapable of crystallization; unites with alkalies, earths, and some metallic oxyds, forming, for the most part, brown and foul-looking compounds, generally deliquescent.

*Pyroligneous acid* is also called *ligneous acid*, and *acid of wood*. To procure it, distil in a glass or earthen retort any quantity of shavings of any kind of wood, as box, guaiacum, or beech, and adapt a large receiver, not closely luted. By this means, an extremely strong smelling, dark-coloured empyreumatic acid liquor will be obtained, nearly one-third of the weight of the wood. It is the sourest, and blackest, and most empyreumatic of all these acids, and seems to require a stronger heat than the rest for its production. It is obtained in large quantities near London from the preparation of charcoal for gunpowder, by distilling wood in cast-iron cylinders. It stains the hands deeply, and wood indelibly.

The *pyromucous acid* is also called *syrupous acid* and *empyreumatic acid of sugar*, which must be carefully distinguished from the proper acid of sugar or oxalic acid, which is quite another substance. The pungent acid vapour of sugar or any saccharine matter strongly heated must be familiar to all who have ever entered a sugar-baking house. It may be also prepared by putting into a glass retort any quantity of pulverized sugar of any kind, so as to fill only one eighth part of it, as the matter swells prodigiously in the process; a large, not closely luted receiver must be adapted to it; and it should be heated gradually on a sand-bath. A vast quantity of gas arises as the sugar begins to scorch, which is mostly carbonic acid mixed with an inflammable gas, probably the gaseous oxyd of carbon. In the receiver is condensed a weak acid brown liquor, coloured by an oily matter, and also apparently fouled by a portion of fuliginous matter volatilized during the distillation. The quantity of acid obtainable in this process varies according to the regulation of the fire, which should at least be pushed so as to make the retort red-hot, and to reduce the sugar to a perfect charcoal; but in general about five-eighths of the weight of sugar may be obtained of the distilled acid.

Gum mucilage, manna, honey, starch and other mucus, or muco-saccharine substances, yield by distillation the same acid as sugar.

The *pyrotartareous acid* is also sometimes called *emphyreumatic acid* of tartar, but must be carefully distinguished from proper tartareous acid, which is altogether of a different nature.

To procure the pyrotartareous acid, distil any quantity of cream of tartar in a glass or earthen retort, as in the last process; the retort in this case may be half full of the tartar. On raising the fire very slowly, the first product is a limpid, acidulous, somewhat bitterish water; after which, as the heat increases, a most prodigious volume of the inflammable gas is given out, together with a stronger acid, and more emphyreumatic liquid, and at last a black oil, and some volatile alkali. The whole quantity of liquid acid procured from tartar in this method is generally not more than about a quarter of the weight of the tartar, and is not quite so brown nor so highly emphyreumatic as in the former acid.

By purification, all these acids lose their distinctive characters, and are reduced to simple acetous acids; and as such are sometimes employed in the preparation of acetous ether; and at other times, even without much purification, in forming the acetited iron used as a mordant by the calico-printers. The distillation is one means of purifying them: newly burnt charcoal is still more powerful, and an union with lime or an alkali most of all.

**PYROMACHUS**, in mineralogy, a genus of the class earths, order siliceous. Consisting principally of silica, with a small portion of alumina, and oxyd of iron, and frequently a little carbonat of lime; hard, semi-transparent, lightish, of a conchoidal texture, breaking into indeterminate, very acute angled fragments, rarely separating into concentrically crustose fragments, with hardly any lustre, found chiefly in stratorial mountains, and rarely forming strata itself; not fusible *per se* before the blowpipe. Five species.

1. *P. cinereus*. Cinereous flint. Greyish, approaching to subopaque, and of a somewhat splintery texture. Found detached in Lusace, and on Mount Mosseburg in Westrogoth, covered with a hard, white, marmoreous crust; approaching to a petrosilex.

2. *P. striata*. White, of a texture approaching to fibrous. Found on the cretaceous hills of England.

3. *P. cretaceus*. Flint. Common flint. Tinged, semi-transparent, of a perfectly conchoidal texture. Found in Britain, France, Denmark, and other European countries, in detached pieces of various shapes and sizes, and generally covered with a white calcareous coat; most common among chalk, and often arrang-

ed in some kind of stratarial order; colour varying from honey-yellow to brownish-black, with variations often in the same specimen, in the form of veins, stripes, clouds, or dots; frequently contains petrifications, particularly of the crustaceous and small coralline kinds, and sometimes bears the impression of echinites and belemnites: when two pieces are rubbed smartly together, they phosphoresce and emit a peculiar odour; when heated, it decrepitates, and becomes white and opaque; specific gravity from 2,580 to 2,630: contains

|                        |       |
|------------------------|-------|
| Silica . . . . .       | 98,00 |
| Lime . . . . .         | 0,50  |
| Alumina . . . . .      | 0,25  |
| Oxyd of iron . . . . . | 0,25  |
| Water . . . . .        | 1,00  |

100, *Klaproth*.

4. *P. semipellucidus*. Light, nearly semi-transparent. Found in France, Wirtemberg, Franconia, and Iceland, generally mixed with the last, but more rare; colour white, honey-colour, reddish, blueish or variegated.

5. *P. crystallinus*. Crystallized in a three-sided depressed pyramid. Two varieties.

a. The pyramid simple. Found in Saxony, near Schneeberg.

b. The pyramid double. Found in Saxony, near Johanngeorgenstadt.

**PYROMANCY**. (*πυρομαντεία*.) A kind of divination performed by means of fire.

The ancients imagined they could foretel futurity by inspecting fire and flame: to this end they considered its direction, or which way it turned. Sometimes they added other matters to the fire, e. gr. a vessel full of urine, with its neck bound about with wool, watching narrowly on which side it would burst, and thence taking their augury.

**PYROMETER**. (formed of *πυρ*, fire, and *μετρον*, I measure.) In physics, the name of a machine contrived to measure the alteration of the dimensions of metals, and other solid bodies, arising from heat.

Muschenbroek was the first inventor of this instrument; though it has since received several improvements by other philosophers. He has given a table of the expansions of the different metals, with various degrees of heat. Having prepared cylindric rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; then successively with three, four, and five flames. The effects were as in the following table: where the degrees of expansion are marked in parts equal to the 12500th part of an inch.

# P Y R O M E T E R.

| Expansion of                     | Iron | Steel | Copp. | Brass | Tin | Lead |
|----------------------------------|------|-------|-------|-------|-----|------|
| By 1 flame                       | 80   | 85    | 89    | 110   | 153 | 155  |
| By 2 flames                      | 117  | 123   | 115   | 220   |     | 274  |
| placed close together            |      |       |       |       |     |      |
| By 2 flames at 2½ inches distant | 109  | 94    | 92    | 141   | 219 | 263  |
| By 3 flames close together       | 142  | 168   | 193   | 275   |     |      |
| By 4 flames close together       | 211  | 270   | 270   | 361   |     |      |
| By 5 flames                      | 230  | 310   | 310   | 377   |     |      |

Tin easily melts when heated by two flames placed close together; and lead with three flames close together, when they burn long.

It hence appears that the expansions of any metal are in a less degree than the number of flames; so two flames give less than a double expansion, three flames less than a triple expansion, and so on, always more and more below the ratio of the number of flames. And the flames placed together cause a greater expansion, than with an interval between them.

For the construction of Muschenbroek's pyrometer, with alterations and improvements upon it by Desaguliers, see Desag. Exper. Philos. vol. 1. pa. 421; see also Muschenbroek's translation of the Experiments of the Academy del Cimento, printed at Leyden in 1731; and for a pyrometer of a new construction, by which the expansions of metals in boiling fluids may be examined and compared with Fahrenheit's thermometer, see Muschenb. Introd. ad. Philos. Nat. 4to, 1762, vol. 2, pa. 610.

But as it has been observed, that Muschenbroek's pyrometer was liable to some objections, these have been removed in a good measure by Ellicott, who has given a description of his improved pyrometer in the Philos. Trans. numb. 443; and the same may be seen in the Abridg. vol. 8, pa. 464. This instrument measures the expansions to the 7200th part of an inch; and by means of it, Mr. Ellicott found, upon a medium, that the expansions of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as below:

Gold, Silver, Brass, Copper, Iron, Steel, Lead.  
73 103 95 89 60 56 149

The great difference between the expansions of iron and brass, has been applied with good success to remove the irregularities in pendulums arising from heat. Philos. Trans. vol. 47, pa. 485.

Mr. Graham used to measure the minute expansions of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very

lightly hung, was capable of agreement within the 3000 or 4000th part of an inch. And on this general principle Mr. Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw. This instrument makes the expansions sensible to the 2345th part of an inch. And when it is used, both the instrument and the bar, to be measured, are immersed in a cistern of water, heated to any degree, up to boiling, by means of lamps placed under the cistern; and the water communicates the same degree of heat to the instrument and bar, and to a mercurial thermometer immersed in it, for ascertaining that degree.

With this pyrometer Mr. Smeaton made several experiments, which are arranged in a table; and he remarks, that their result agrees very well with the proportions of expansions of several metals given by Mr. Ellicott. The following table shows how much a foot in length of each metal expands by an increase of heat corresponding to 180 degrees of Fahrenheit's thermometer, or to the difference between the temperatures of freezing and boiling water, expressed in the 10000th part of an inch.

|                                                   |     |
|---------------------------------------------------|-----|
| 1. White glass barometer tube                     | 100 |
| 2. Martial regulus of antimony                    | 130 |
| 3. Blistered steel                                | 128 |
| 4. Hard steel                                     | 147 |
| 5. Iron                                           | 151 |
| 6. Bismuth                                        | 167 |
| 7. Copper, hammered                               | 204 |
| 8. Copper 8 parts, mixed with 1 part tin          | 218 |
| 9. Cast brass                                     | 225 |
| 10. Brass 16 parts, with 1 of tin                 | 229 |
| 11. Brass wire                                    | 232 |
| 12. Speculum metal                                | 232 |
| 13. Spelter solder, viz. 2 parts brass and 1 zinc | 247 |
| 14. Fine pewter                                   | 274 |
| 15. Grain tin                                     | 298 |
| 16. Soft solder, viz. lead 2 and tin 1            | 301 |
| 17. Zinc 8 parts with tin 1, a little hammered    | 323 |
| 18. Lead                                          | 344 |
| 19. Zinc or spelter                               | 353 |
| 20. Zinc, hammered half an inch per foot          | 373 |

For a farther account of this instrument, with its use, see *Philos. Trans.* vol. 48, pa. 598.

Mr. Ferguson has constructed, and described a pyrometer (*Lect. on Mechanics*, Suppl. pa. 7, 4to), which makes the expansion of metals by heat visible to the 45000th part of an inch. And another plan of a pyrometer has lately been invented by M. De Luc, in consequence of a hint suggested to him by Mr. Ramsden: for an account of which, with the principle of its construction and use, both in the comparative measure of the expansions of bodies by heat, and the measure of their absolute expansion, as well the experiments made with it, see M. De Luc's elaborate essay on pyrometry, &c. in the *Philos. Trans.* vol. 68, pa. 419—546.

Mr. Wedgwood contrived a curious pyrometer, in which he employed small cubes of dry clay; because that species of earth has the remarkable property of contracting in its bulk when submitted to the fire, and not again expanding, on suddenly exposing it to the cold air. In order to ascertain the precise degree of heat in an oven, he puts one of his clay cubes into it; and, after having acquired the temperature of the place, he immediately plunges it into cold water. Now, the size of the cube (that was exactly adjusted to half an inch square), is measured between two brass rules, the sides of which are somewhat obliquely disposed, so as to form an inclining groove into which the cube may be slid. In proportion as the bulk of the latter has been contracted by heat, it passes down deeper between the scales, on which the various degrees of temperature have been previously marked. Thus, when the division of the scale commences from the point of red heat visible in day-light, and the whole range be divided into 240 equal parts, it will be found that Swedish copper melts at 28; gold at 32; iron at from 130 to 150 degrees: above this point, the cubes could not be heated.

But M. Fourny has, however, given in the *Journal des Mines*, a paper on this subject, in which he shows, that the effect of shrinking does not result solely and invariably from the cause to which it is ascribed, and that it is far from necessarily proportionate to it. See *Repository of Arts*, No. 38. N. S.

**PYRO-MUCOUS ACID.** *Acidum pyromucosum.* Syrupous acid! The acid liquor obtained by distillation from insipid, saccharine, gunny, farinaceous mucilages. The celebrated Gren is of opinion, that it is a mixture of acetic with oxalic acid, and does not deserve to be received in the system of chemistry as a peculiar acid. See **PYRO-LIGNEOUS ACID**.

**PYROPHORUS**, in chemistry, the name by which several of the phosphori were at first denominated, and especially those of Homberg and Kunkell. See the article **PHOSPHORUS**. It is now chiefly confined to one of the simplest and least oporose of the phosphorescent compounds, and which is prepared by exposing to

heat in an iron pot three parts of alum and one part of sugar or of flour: the mixture liquefies, and is to be stirred constantly till the whole becomes grey, and easily reducible to powder while hot.

The coarse powder is put into a coated phial, so as nearly to fill it; the mouth of the phial is stopped with a small plug of clay, and is placed in a crucible, and surrounded with sand up to the neck. The crucible is heated to redness, until a blue flame appears at the mouth of the phial; when this has continued ten minutes, the crucible is removed from the fire, and the phial, when sufficiently cold, is accurately stopped. This substance inflames in atmospheric air; in a moist atmosphere, the inflammation is much more speedy, and in a dry air, it can scarcely take place. It burns also very brilliantly in oxygen gas, in nitrous gas, and in oxy muriatic acid gas; and is inflamed by the sulphuric and nitric acids.

**PYROSIS.** (*πυρσις*, from *πυρ*, to burn.) The heart-burn. A genus of disease in the class neuroses and order spasmi of Cullen; known by a burning pain in the stomach, attended with copious eructation, generally of a watery insipid fluid.

**PYROSOMA**, in natural history, a genus of the class vermes, order mollusca. Body lengthened and tubular, open at one extremity and closed at the other; scattered over with numerous soft papillæ. One species only, *P. phosphorica*; the colour of which when at rest is a pale greenish blue; but when in motion, which is performed by the alternate contraction and dilatation of the body, the whole appears in the highest degree of phosphoric lustre, passing through all the colours of a bar of red-hot iron till it becomes of what is termed a white-heat: after which it again passes into the colour of red-hot iron, and from that gradually declines into its original greenish hue. Length from three to five inches, diameter a fourth or fifth of the length. A native of the Atlantic ocean, in some parts of which it is seen in great multitudes, and irradiates the waves with its fiery brilliancy. See *Nat. Hist. Pl.* CLXIV.

**PYROSTRIA**, in botany, a genus of the class tetrandria, order monogynia. Calyx very minute, four-toothed; corol campanulate, five-cleft, with a downy throat; drupe pear-shaped, inferior, eight-striate; nuts eight, one-seeded. One species; a small tree of Mauritius.

**PYRO-TARTRITS.** Salts formed by the combination of the pyro-tartrous acid with different bases.

**PYRO-TARTROUS ACID.** *Acidum pyrotartrosum.* See **TARTAR** (Spirit of),

**PYROTECHNICAL.** *a.* (*pyrotechnique*, Fr. from *pyrotechnics*.) Engaged or skilled in fireworks.

**PYROTECHNICS.** *s.* (*πυρ* and *τεχνη*.) The art of employing fire to use or pleasure; the art of fireworks.

**PYROTECHNY.** (*πυροτεχνια*, formed from *πυρ*, fire, and *τεχνη*, art.) The art of fire, or a

science which teaches the management and application of fire in several operations.

Pyrotechny is of two kinds, military and chemical.

*Military pyrotechny* is the doctrine of artificial fireworks, and fire-arms, teaching the structure and use both of those employed in war for the attacking of fortifications, &c. as gunpowder, cannons, bombs, granadoes, carcases, mines, fuses, &c. and of those made for amusement-sake, as squibs, crackers, rockets, wheels, Chinese-fire, water-rockets, serpents, gerbs, illuminated globes, &c.

Some call pyrotechny by the name artillery; though that word is usually confined to the instruments used in war. Others choose to call it pyrobology, or rather pyroballogy, q. d. the art of missile fires, from the Greek πυρ, fire, and βαλλειν, to cast, or throw.

Wolfius has reduced pyrotechnia into a kind of mixt mathematical art: indeed it will not allow of geometrical demonstrations; but he brings it to tolerable rules and reasons; whereas, before, it had used to be treated by authors at random, and without regard to any reasons at all.

See the elements of military pyrotechny under the several instruments and operations, **CANNON, BOMB, ROCKET, GUNPOWDER, &c.**

*Chemical pyrotechny* is the art of managing and applying fire in distillations, calcinations, and other operations of chemistry.

Some reckon a third kind of pyrotechnia, viz. the art of fusing, refining, and preparing metals.

**PYRRHA.** The most celebrated of this name is a daughter of Epimetheus and Pandora, who married Deucalion, the son of Prometheus, who reigned in Thessaly. When all mankind were destroyed by a deluge, she alone with her husband escaped in a boat which Deucalion had made. When the waters had subsided, Pyrrha, with her husband, went to the oracle of Themis, where they were directed, to repair the loss of mankind, by throwing stones behind their backs. They obeyed, and the stones which Pyrrha threw were changed into women, and those of Deucalion into men. (See **DEUCALION**.)

**PYRRHICHIUS.** (Πυρρικός.) In the Greek and Latin poetry, a foot consisting of two syllables, both short; as *deus*.

Among the ancients this foot is also called *periambus*; by others *hegemonia*.

**PYRRHO**, a philosopher of Elis, disciple to Anaxarchus, and originally a painter. He was in continual suspense of judgment, he doubted of every thing, never made any conclusions, and when he had carefully examined a subject, and investigated all its parts, he concluded by still doubting its evidence. This manner of doubting in the philosopher has been called *Pyrrhonism*, and his disciples have received the appellation of *sceptics*, &c. He pretended to have acquired an uncommon dominion over opinion and passions. He flourished B. C. 304, and died at the advanced age of 90.

**PYRRHONISM.** Scepticism. See **PYRRHO**.

**PYRRHUS.** (See **NEOPTOLEMUS**.) A celebrated king of Epirus, descended from Achilles, by the side of his mother, and from Hercules by that of his father, and son of *Æacides* and *Phthia*. When his father, who had been banished from his kingdom, was carried to the court of Glautias king of Illyricum, who educated him with great tenderness, Cassander, king of Macedonia, wished to dispatch him, but Glautias not only refused to deliver him up, but even went with an army, and placed him on the throne of Epirus, though only twelve years of age. About five years after, he was expelled his throne by Neoptolemus, and applied to his brother-in-law Demetrius for assistance. He accompanied Demetrius at the battle of Ipsus, and fought there with all the prudence of an experienced general. He afterwards attempted the recovery of his throne, and was successful in the undertaking. In the subsequent years of his reign, Pyrrhus engaged in the quarrels which disturbed the peace of the Macedonian monarchy, and was meditating new conquests, when the Terentines invited him into Italy to assist them against the Romans. He gladly accepted the invitation; but his passage into Italy, across the Adriatic, proved nearly fatal to him. He lost the greatest part of his troops in a storm. At his entrance into Tarentum, B. C. 280, he began to introduce the strictest discipline among their troops, to accustom them to despise dangers. In the first battle with the Romans, he obtained the victory, through his elephants, whose bulk and uncommon appearance astonished the Romans. The number of the slain was equal on both sides, and the conqueror said that such another victory would totally ruin him. Though victorious, he sued for peace, but his offers of peace were refused. Another battle was soon after fought near Asculum, where the Romans and their enemies reciprocally claimed the victory. His fondness of novelty, however, soon determined him to quit Italy; he accordingly left a garrison at Tarentum, and crossed over to Sicily, by whose inhabitants he had been invited, where he obtained two victories over the Carthaginians, and took many of their towns. Having returned to Tarentum, he renewed hostilities with the Romans; but when his army of 80,000 men had been defeated by 20,000 of the enemy, under Curius, he left Italy with precipitation, B. C. 274, mortified by the victories which had been obtained over one of the descendants of Achilles. In Epirus he began to repair his military character, by attacking Antigonus, and he was at last restored to the throne of Macedonia. He afterwards marched against Sparta, but was obliged to retire to Argos, where, through the treachery of Aristeus, a bloody conflict ensued, during which, a woman, who saw Pyrrhus just going to kill her son, threw from the top of the house a tile, which brought the king to the ground. His head was cut off, and carried to Antigonus,

272 years B. C. Pyrrhus has been deservedly commended for his talents as a general; and not only his friends, but also his enemies, have been warm in extolling him. The Romans passed great encomiums upon him, and Pyrrhus was no less struck with their magnanimity and valour; so much so, indeed, that he exclaimed, that if he had soldiers like the Romans, or if the Romans had him for a general, he would leave no corner of the earth unseen, and no nation unconquered.

**PYRSTEIN**, a town of Bavaria, in the principality of Passau, insulated in Austria. It is 10 miles N.W. of Lintz, and 22 E. of Passau.

**PYRUS**, in botany, a genus of the class *icosandria*, order *pentagynia*. Calyx five-cleft; petals five; styles from two to five; pome inferior, from two to five-celled; seeds two in each cell.

This character will include both the *pyrus* and *sorbus* of Linnéus: and consequently the genus will comprize twenty-four species, chiefly natives of Europe, many of America, a few of Asia; seven common to our own mountains, woods, or hedges.

The cultivated species are the following:

1. *P. communis*. Pear tree. Tree lofty; branches upright; pendulous; leaves ovate, serrate; flowers corymbed, of a snow-white colour; fruit a pome. A native of our own woods. The wild pear, however, the mother of all the orchard and garden varieties, is thorny, with white or reddish, desidious, setaceous stipules; peduncles alternate: calyx clothed with a ferruginous wool.

The varieties are almost innumerable; they may be seen in the books upon gardening, but we cannot detail them in this work.

2. *P. malus*. Apple tree. Crab tree. Spreading; twigs and branches irregular and twisting, more horizontal than in the first; umbels sessile; leaves ovate-pointed, serrate; glabrous; claws of the petals shorter than the calyx; styles glabrous. Found wild in our hedges; and in this state, like the wild pear, this also is armed with thorns: it is then called crab or wilding. Like the last, its varieties are too numerous to be detailed.

3. *P. spectabilis*. Chinese apple tree. Umbels sessile; leaves oval-oblong, serrate, smooth; claws of the petals longer than the calyx, styles woolly at the base. A native of China; highly ornamented when in blossom, which takes place about the end of April or beginning of May: flowers large, of a pale-red when open and semi-open; the buds of a much deeper hue. Fruit sparingly produced, and of little value.

4. *P. prunifolia*. Siberian crab tree. Strong woody stem, sending out many side-branches, and covered with a smooth, brown bark: umbels sessile; peduncles pubescent; styles woolly at the base; leaves ovate, pointed, serrate. A native of Siberia. There are varieties in the size of the fruit.

5. *P. coronaria*. Sweet-scented crab tree. Leaves hearted, cut, serrate, angular, glabrous;

peduncles corymbed, and together, with the calyx glabrous; flowers of a fragrant odour. A native of America, where the inhabitants plant it to graft apples upon.

6. *P. cydonia*. Quince-tree. Low, crooked, distorted in its stem, covered with a brown bark, and branchy; leaves very entire; flowers solitary, large, pale-red or white; calyx spreading; serrate; fruit a pome, varying in shape in different varieties, globular, oblong, or pear-formed: flowers in May and June; a native of Austria.

7. *P. aira*. White beam-tree. Leaves roundish-ovate, cut, serrate, with parallel veins, white-downy underneath; flowers corymbed; styles from two to four. Found wild on the rocky mountains of our own country.

8. *P. aucuparia*. Mountain-service, mountain ash, quicken-tree, quick-beam, or roan-tree. Elegant in form; of slow growth; wood tough, close-grained, not very hard; bark smooth, grey; young branches purplish-brown; leaves pinnate; leaflets equal, nearly glabrous on both sides, serrate; flowers corymbed; styles three or four; fruit bright red, or scarlet, when ripe, nearly round, size of a large pea, juicy, astringent: blackbirds and thrushes so fond of it as generally to destroy it before all its beauty is fully displayed by being perfectly coloured and ripe.

9. *P. domestica*. True service, or sorb-tree. Size middling, resembling the preceding; not flowering till of great age; wood very hard; leaves pinnate; leaflets equal, villous underneath, serrate at top; flowers in panicles; fruit pear-shaped, reddish and spotted, extremely austere, and not eatable till mellowed by frost or time, when it becomes brown and very soft. A native of our own woods, and flowers in May.

There are several varieties with apple-shaped fruit, oval fruit, turbinated fruit, compressed fruit.

10. *P. hybrida*. Bastard service, or mountain ash. Tree middle-sized; leaves pinnate at the base, white-downy underneath; flowers corymbed; styles three or four: fruit as in *pyrus aucuparia*, but somewhat larger. It is perhaps only a hybrid plant from the two preceding.

The three last species form the genus *sorbus* of several writers.

The first seven kinds are raised by grafting and budding upon any sort of pear-stocks; occasionally upon quince-stocks, and sometimes upon white-thorn stocks: the first answer best for general use and for large trees; the other two for trees of a more moderate size, for dwarfs and wall trees.

The services are generally raised by seeds or layers; the first is the best method.

Pear-trees planted either against walls or in espaliers should have thirty feet allowed as their interval. These trees commonly produce their blossom-buds first at the extremity of their last year's shoots; and hence they require a peculiar mode of pruning, as the common mode would take off the part which should bear the

fruit, and produce new shoots from the same branch that would unnecessarily crowd the tree with wood. Pear-trees ought therefore to be carefully examined in summer, and have their foreright shoots taken off, by which means the fruit will not be over-shaded, and the trees will need but little winter-pruning. The several sorts of summer-pears all ripen best in espaliers, but the winter-pears require a south-east or south-west, or else an east wall.

The several sorts of *apples* are designed either for standards, or in dwarfs, or espaliers: those that are designed for standards should be grafted on crab-stocks, and those for dwarfs or espaliers, on the codling; or some other sort, which does not shoot freely.

The best season for planting out these trees is, if the soil is dry, in October; but in a wet soil, it is best to defer it till February. The distance at which they should be planted is forty feet square, that the sun and air may have room to come every way at them. And it is a very good method in large orchards, to plough and sow the ground between them, till they are grown up. Good thriving trees, of about three years grafting, are to be chosen for planting; and they should be taken from a soil as nearly as possible of the same nature with that they are to be planted into, or rather from one that is something poorer. In preparing these trees for planting, all the broken or bruised roots are to be taken off, as also all such as cross or gall one another, and all small fibres; for they seldom survive a remove. Some of the most luxuriant branches must also be taken off at the same time, and others shortened, but the head should by no means be cut off. The holes for the planting them should be made about two feet deep, and of a breadth proportioned to the extent of the root; the bottom must be made even, and the clods and lumps all broken. The tree is then to be set in the middle of the hole, and placed as upright as possible, and the earth carefully placed about its roots; and, finally, trod down about it with the feet; and if the weather be dry, every tree should have a good watering, which will fix the earth to the roots. A stake should also be fixed by the side of each tree to tie it to, that the wind may not shake it and loosen the roots. The foot of each tree should be then surrounded with turf newly cut, with the green side downwards; which will greatly help to keep the earth moist; and if the season be very dry, the waterings must be repeated at different times; but it is a very common error to water new-set trees too much; and this should be carefully avoided. The year afterwards dig in the earth about the roots, and bury the rotted turf which was laid about the root when planted, and there needs no farther care; the orchard will then thrive of itself. Dwarf standards are of the least value of all apple-trees, never producing well-tasted fruit; and therefore the worst way of managing this tree. Espaliers are commonly planted to surround the quarters of kitchen gardens. These quarters should be made as large as the garden-room will permit. The trees should be planted at six-

teen or eighteen feet asunder, if on crab-stocks, but if on paradise-stock, twelve feet will be sufficient; when these are planted in the manner above described, they should be headed to about four eyes above the graft, and they should never be of more than two years old from the grafting when planted. The summer after they are planted, a number of small stakes must be provided, of about three feet long, to drive into the ground on each side of the trees, four to each tree; and to these stakes the new shoots must be fastened as horizontally as possible. If the trees have taken kindly, probably about Michaelmas all the four eyes will have made shoots; if so, at Michaelmas, which is the right time for pruning, the two upper shoots should be cut off to four eyes each, but the undermost may be left with six or eight; but the branches should never be shortened in summer, unless on occasion of filling up some vacancy in the espalier, and then this must not be done after May. In the second year, all the shoots must be trained horizontally, except the fore-right ones, which must be displaced as fast as they are produced: at Michaelmas, the branches in the middle of the tree, or wherever there is a want of wood, must be shortened; but after this be very careful of any great lopping, or shortening of branches, but leave them at full length, training them all horizontally.

The quince-tree affords a great variety of fruit. The several sorts are easily propagated, either by layers, suckers, or cuttings, which must be planted in a moist soil. Those raised from suckers are seldom so well rooted as the others; and are subject to produce suckers again, in a greater abundance, which is not to be wished in fruit-bearing trees. The cuttings should be planted early in the autumn; and, in dry weather, must be often watered, to assist them in rooting; the second year they should be removed into the nursery, and set in rows at three feet distance, and one foot asunder in each row. In two or three years more, they will be fit to transplant where they are to stand, which should always be near a ditch, or river, or in some moist soil; where they will produce twice the quantity of fruit that they will in a dry one, and the fruit will also be much larger; but those in a drier soil are better tasted, and are earlier ripe.

The services, when in young plants, should be kept clear from weeds and watered in dry weather: they should be exposed to the open air, and the seed being sown in the spring, the plants should be transplanted about the middle of October, into a warm, light spot of ground, two feet asunder, in rows at a foot distance from each other. In winter the roots should be covered with mulch; and in this kind of nursery the plants may continue three or four years, when they should be again transplanted to the places where they are designed to remain: they succeed best in a strong, moist soil, and a warm situation.

PYTHAGORAS, in biography, one of the greatest philosophers of antiquity, was born about the forty-seventh Olympiad, or 590 years

## P Y T H A G O R A S.

before Christ. His father's principal residence was at Samos; but being a travelling merchant, his son Pythagoras was born at Sidon, in Syria; but soon returning home, our philosopher was brought up at Samos, where he was educated in a manner that was answerable to the great hopes that were conceived of him. He was called "the youth with a fine head of hair;" and from the great qualities that soon appeared in him, he was regarded as a good genius sent into the world for the benefit of mankind.

Samos, however, afforded no philosophers capable of satisfying his thirst for knowledge; and therefore, at eighteen years of age, he resolved to travel in quest of them elsewhere. The fame of Pherecydes drew him first to the island of Syros; from hence he went to Miletus, where he conversed with Thales. He then travelled to Phœnicia, and stayed some time at Sidon, the place of his birth; and from hence he passed into Egypt, where Thales and Solon had been before him.

Having spent twenty-five years in Egypt, to acquire all the learning and knowledge he could procure in that country; with the same view he travelled through Chaldea, and visited Babylon. Returning after some time, he went to Crete; and from hence to Sparta, to be instructed in the laws of Minos and Lycurgus. He then returned to Samos; which, finding under the tyranny of Polycrates, he quitted again, and visited the several countries of Greece. Passing through Peloponnesus, he stopped at Pholius, where Leo then reigned; and in his conversation with that prince, he spoke with so much eloquence and wisdom, that Leo was at once ravished and surprised.

From Peloponnesus he went into Italy, and passed some time at Heraclea and at Tarentum; but made his chief residence at Croton; where, after reforming the manners of the citizens by preaching and establishing the city by wise and prudent counsels, he opened a school, to display the treasures of wisdom and learning he possessed. It is not to be wondered that he was soon attended by a crowd of disciples, who repaired to him from different parts of Greece and Italy. He had a college in his own house, which he denominated *μαθησιον*, in which there were two classes of students, viz. *εἰσρωτοι* (who were also called *auscultantes*) and *εὐρωτοι*. The former of these were probationers, and were kept under a long examen. A silence of five years was imposed upon them; which Apuleius thinks was intended to teach them modesty and attention; but Clemens Alexandrinus thinks it was for the purpose of abstracting their minds from sensible objects, and inuring them to the pure contemplation of the Deity. The latter class of scholars were called *genuini*, *perfecti*, *mathematica*, and, by way of eminence, Pythagoreans. They alone were admitted to the knowledge of the arcana, and depths of Pythagoric discipline, and were taught the use of ciphers and hieroglyphic writings.

Clemens observes, that these orders corresponded very exactly to those among the Hebrews: for in the schools of the prophets there were two classes, viz. the sons of the prophets, who were the scholars, and the doctors or masters, who were also called *perfecti*; and among the Levites, the novices or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the proselytes there were two orders: *exoterici*, or proselytes of the gate; and *intrinseci* or *perfecti*, proselytes of the covenant. He adds, it is highly probable that Pythagoras himself had been a proselyte of the gate, if not of the covenant. Gale endeavours to prove that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers and ancient authors, and even pointing out the tracks and footsteps of Moses in several parts of Pythagoras's doctrine. But we believe the learned author was misled by the Christian Platonists.

The necessity of concealing their mysteries induced the Egyptians to make use of three sorts of styles, or ways of expressing their thoughts: the simple, the hieroglyphical, and the symbolical. In the simple, they spoke plainly and intelligibly, as in common conversation; in the hieroglyphical, they concealed their thoughts under certain images and characters; and in the symbolical, they explained them by short expressions, which, under a sense plain and simple, included another wholly figurative. Pythagoras borrowed these three different ways from the Egyptians in all the instructions he gave; but chiefly imitated the symbolical style, which he thought very proper to inculcate the greatest and most important truths; for a symbol, by its double sense, the proper and the figurative, teaches two things at once; and nothing pleases the mind more than the double image it represents to our view. In this manner Pythagoras delivered many excellent things concerning God, and the human soul, and a great variety of precepts, relating to the conduct of life, political as well as civil; he made also some considerable discoveries and advances in the arts and sciences. Thus, among the works ascribed to him, there are not only books of physic and books of morality, like that contained in what are called his Golden Verses, but treatises on politics and theology. All these works are lost; but the vastness of his mind appears from the wonderful things he performed. He delivered, as antiquity relates, several cities of Italy and Sicily from the yoke of slavery; he appeased seditions in others; and he softened the manners, and brought to temper the most savage and unruly spirits of several people and tyrants. Phalaris, the tyrant of Sicily, it is said, was the only one who could withstand the remonstrances of Pythagoras; and he it seems was so enraged at his discourses, that he ordered him to be put to death. But though the lectures of the philosopher could make no impression on the tyrant, yet they

were sufficient to reanimate the Sicilians, and to put them upon a bold action. In short, Phalaris was killed the same day that he had fixed for the death of the philosopher.

Pythagoras had a great veneration for marriage; and therefore himself married at Croton a daughter of one of the chief men of that city, by whom he had two sons and a daughter. One of the sons succeeded his father in the school, and became the master of Empedocles. The daughter, named Damo, was distinguished both by her learning and her virtues, and wrote an excellent commentary upon Homer. It is related, that Pythagoras had given her some of his writings, with express commands not to impart them to any but those of his own family; to which Damo was so scrupulously obedient, that even when she was reduced to extreme poverty, she refused a great sum of money for them.

From the country in which Pythagoras thus settled and gave his instructions, his society of disciples was called the Italic sect of philosophers, and their reputation continued for some ages afterwards, when the Academy and the Lycæum united to obscure and swallow up the Italic sect.

Pythagoras's disciples regarded the words of their master as the oracles of a god; his authority alone, though unsupported by reason, passed with them for reason itself; they looked upon him as the most perfect image of God among men. His house was called the temple of Ceres, and his court-yard the temple of the Muses; and when he went into towns, it was said he went thither, not to teach men, but to heal them.

Pythagoras was persecuted by bad men in the last years of his life, and some say he was killed in a tumult raised by them against him; but according to others, he died a natural death at 90 years of age, about 497 years before Christ.

Beside the high respect and veneration the world has always had for Pythagoras, on account of the excellence of his wisdom, his morality, his theology, and politics, he was renowned as learned in all the sciences, and a considerable inventor of many things in them; as arithmetic, geometry, astronomy, music, &c. In arithmetic, the common multiplication table is, to this day, still called Pythagoras's table. In geometry, it is said he invented many theorems, particularly these three:—1. Only three polygons, or regular plane figures, can fill up the space about a point; viz. the equilateral triangle, the square, and the hexagon. 2. The sum of the three angles of every triangle is equal to two right angles. 3. In any right-angled triangle the square on the longest side is equal to both the squares on the two shorter sides. For the discovery of this last theorem, some authors say, he offered to the gods a hecatomb, or a sacrifice of a hundred oxen. Plutarch, however, says it was only one ox; and even that is questioned by Cicero, as inconsistent with his doc-

trine, which forbade bloody sacrifices. The more accurate therefore say, he sacrificed an ox made of flour, or of clay, and Plutarch even doubts whether such sacrifice, whatever it was, was made for the said theorem, or for that concerning the parabola, which it was said Pythagoras also found out.

In astronomy his inventions were many and great. It is reported that he discovered or maintained the true system of the world, which places the sun in the centre, and makes all the planets revolve about him: from him it is to this day called the old, or Pythagorean system; and is the same as that which was revived by Copernicus. He first discovered that Lucifer and Hesperus were but one and the same, being the planet Venus, though formerly thought to be two different stars. The invention of the obliquity of the zodiac is likewise ascribed to him. He first gave to the world the name Kosmos, from the order and beauty of all things comprehended in it; asserting that it was made according to musical proportion; for as he held that the sun, by him and his followers termed the fiery globe of unity, was seated in the midst of the universe, and the earth and planets moving around him, so he held that the seven planets had an harmonious motion, and their distances from the sun corresponded to the musical intervals or divisions of the monochord.

Pythagoras and his followers held the transmigration of souls, making them successively occupy one body after another; on which account they abstained from flesh, and lived chiefly on vegetables.

**PYTHAGOREANS**, a sect of ancient philosophers, so denominated from their being the followers of Pythagoras of Samos. See **PYTHAGORAS**.

**PYTHAGOREAN TABLE**, the multiplication table.

**PYTHEAS**, a native of Massilia, famous for his knowledge of astronomy, mathematics, philosophy, and geography. He advanced far into the northern seas, and discovered the island of Thule, and entered the sea now called the Baltic. His discoveries in astronomy and geography were ingenious, and he was the first who established a distinction of climate by the length of days and nights. Pytheas lived, according to some, in the age of Aristotle.—2. An Athenian rhetorician, who distinguished himself by his intrigues and opposition to the measures of Demosthenes, of whom he observed, that his orations smelt of the lamp. Pytheas joined Antipater after the death of Alexander the Great.

**PYTHIA**, the priestess of Apollo at Delphi. She delivered the answers of the god, and was supposed to be suddenly inspired by the sulphureous vapours issuing from a subterraneous cavity within the temple, over which she sat bare on a three-legged stool, called a tripod. At this divine inspiration, her eyes suddenly sparkled, her hair stood on end, and a shivering ran over all her body. In this convulsive state she spoke the oracles with lowd howlings, &c. The Pythia, before she placed herself on the tripod,

## P Y T

used to wash her whole body, and particularly her hair, in the waters of the fountain Castalis, at the foot of mount Parnassus. The Pythia appeared dressed in the garments of virgins to intimate their purity, and they were bound to observe the strictest laws of chastity. There was originally but one Pythia, besides subordinate priests, and afterwards two were chosen and sometimes more. The most celebrated of all these is Phemonoe, who is supposed by some to have been the first who gave oracles at Delphi. The oracles were always delivered in hexameter verses, a custom which was some time after discontinued. (See DELPHI ORACULUM.)

**PYTHIAN GAMES.** Games celebrated in honour of Apollo, near the temple of Delphi. They were first instituted, according to the more received opinion, by Apollo himself, in commemoration of the victory which he had obtained over the serpent Python, from which they received the name. Some say they were established by Agamemnon, or by Diomedes, or the council of the Amphictyons, B. C. 1263. They were originally celebrated once in nine years, but afterwards every fifth year. The Romans, according to some, intro-

## P Y X

duced them into their city, and called them Apollinares ludi.

**PYTHON**, a native of Byzantium in the age of Philip of Macedonia. He was a great favourite of the monarch, who sent him to Thebes, when that city, at the instigation of Demosthenes, was going to take up arms against Philip.—2. A celebrated serpent sprung from the mud, which remained on the earth after the deluge of Deucalion. Some suppose it produced by Juno, and sent by the goddess to persecute Latona, then pregnant by Jupiter. (See LATONA.) Apollo, as soon as born, attacked the monster, and killed him with his arrows, and in commemoration of the victory he instituted the celebrated Pythian games.

**PYTHONICE**, an Athenian prostitute greatly honoured by Harbalus, whom Alexander sometime before had intrusted with the treasures of Babylon. He married her, and according to some, she died the very moment that the nuptials were going to be celebrated.

**PYÜRIA.** (from *πύον*, pus, and *ούρος*, urine.) Purulent urine.

**PYX.** *s.* (*pyxis*, Latin.) The box in which the Romanists keep the host.

END OF THE NINTH VOLUME.
